Observations

ON

THE FUTURE OF THE CRIPPLED SAILOR AND SOLDIER.

By C. W. HUTT, M.A., M.D. CANTAB.,
D.P.H. OXON.

THE presence in our midst of crippled sailors and soldiers in ever-increasing numbers renders opportune a short account, necessarily incomplete, of what is being done and what can be done for them. His Majesty the King, when visiting the workshops at Roehampton Hospital for sailors and soldiers who have lost a limb, said: "No effort must be spared to get these men out of the unskilled labour market." The first consideration therefore should be the training of crippled ex-service men in a skilled trade. We are fortunate in this country in being able to draw upon the experience of our gallant ally, France.

THE DISABLED EX-SERVICE MAN IN FRANCE.

The education of disabled soldiers in France is carried out largely at special institutions created for the purpose, *Écoles Professionnelles de Blessés*. Their aim is to teach a new trade to men unable to follow their former occupation, or to afford others an opportunity of re-adapting themselves to their former work.

The first *École Professionnelle* was opened at Lyons in November, 1914; since then more than 20 similar schools have been formed in different parts of the country. In most the men are boarded and lodged at the institution except when they are inhabitants of the town in which the school is situated. Although the funds are in some measure obtained from private sources, the chief standby is an allowance, usually of 3 francs 75 centimes per day per man, provided by the State. It is obviously futile to expect a man in the position of a discharged soldier to take up training when he could be earning some sort of a wage unless it is made worth his while. Not only is no charge made for the training or keep, but a small wage (50 centimes a day as a rule) is paid and the men are given the money resulting from the sale of the articles they make. Dr. Carle, of the Lyons *École*, has found that his greatest difficulty hitherto has been to dispel from the minds of the men that the acceptance of training at an *École Professionnelle* will in some way result in a deduction from their pension or allowance.

The length of the courses varies considerably in the different institutions. Dr. Bourrillon, Directeur de l'Institut National Professionnel des Invalides de la Guerre de St. Maurice (Seine), near Paris, considers that at the end of six months the vast majority of the men who have undergone instruction either in harness-making, boot-making, tailoring, or tin-smithing, &c., are able to earn their living, although, of course, they are not complete masters of the craft. Arrangements should, he thinks, be made that the employer should undertake to arrange for the men to obtain practical experience of the whole of the work undertaken in his workshop.

Most of the *Ecoles Professionnelles de Blessés* arrange for longer courses of training. For example, at the *École Professionnelle* of St. Etienne (Loire) the length of the apprenticeship for the various trades is about 12 months, varying from 10 months for instruction in business methods to 18 months for tailoring. At Bordeaux, where long courses are provided for other occupations, it is considered that four to six months is sufficient to learn basket-making, and three to four months the making of *espadrilles* (shoes with a cotton upper and string sole).

As is only natural, most of the *Ecoles Professionnelles* consider it essential that a pupil should be trained in the school and not in the workshop only; they point out that the manufacturer is concerned chiefly in obtaining the maximum of production, not in creating a good all-round workman. On the other hand, the methods of the *École Professionnelle* are condemned by the manufacturer as being needlessly academic. As a matter of practice, most of the societies

No. 4858.

dealing with disabled soldiers have adopted the principle of providing training at an *École Professionnelle* except where only a few candidates for a particular trade are forthcoming. For instance, at Clermont photography, plumbing, engraving, and the setting of fine stones are taught by employers on their own premises; the school authorities, however, supervise the instruction and the men board and lodge at the school.

A complete exception to the rule occurs at Orleans, where the men are taught only in the workshops of private firms. The St. Maurice Centre not only provides an *École Professionnelle* at St. Maurice, but also an hotel-annexe at Paris for men employed in the workshops of private firms until their earnings enable them to pay their own way.

An example of the action of particular trades in France in supplying training for their trade is found at Elbeuf (Seine Inférieure), a centre of the textile industry, not far from Rouen. At the Elbeuf *École Pratique d'Industrie* free tuition is afforded to discharged soldiers or sailors who have for all practical purposes the complete use of their arms and hands. The instruction provided includes the actual making of the various materials, designing, and the necessary technical training for shop assistants and clerks engaged in the trade. Work will be found for them by a committee formed chiefly of the manufacturers of the district.

EDUCATION OF DISABLED MEN IN THE UNITED KINGDOM.

Although the work for crippled sailors and soldiers has not hitherto been organised so thoroughly in the United Kingdom as in France, yet, taken altogether, a considerable bulk of work has already been done.

Training during convalescence is being carried on to a considerable extent in England. At the Training Centre of the Duchess of Connaught Canadian Red Cross Hospital, Cliveden, Bucks, of which Major Astor, M.P., is the chairman, instruction is afforded during convalescence in land industries as well as workshop crafts. The instructors in land industries are the departmental heads of the Cliveden Estate. The subjects taught include gardening, horticulture, fence-making, horse and pig-keeping. At the workshops the men are engaged in: (i.) Woodcraft industries with and without machinery, including carpentering and toymaking. (ii.) Cigarette-making by machinery; this work is taken up so as to offer a home industry to the men who, with a machine costing from £23 to £25, can make 5000 cigarettes a week, yielding a net profit, allowing for depreciation, of 25s. to 30s. a week.

Advantage has been taken of the unique facilities available at the Heritage Craft Schools, Chailey, the well-known residential institution founded by Mrs. C. W. Kimmins for the teaching of arts and crafts to crippled boys. Part of the institution was taken over by the War Office to serve as a relief hospital for convalescent soldiers, many of whom were suffering from the loss of a limb. To each of the crippled soldiers were assigned as orderlies two crippled boys suffering from the same loss of limb; the men during their physical re-education were enabled to profit by the boys' experience. The soldiers were encouraged to enter the workshops and take advantage of the instruction afforded; they took part eventually in the woodwork, including turning and toymaking, beaten copper-work, book-binding, basket- and rug-making.

At the Roehampton and the Brighton Pavilion Hospitals for limbless sailors and soldiers (Queen Mary's Convalescent Auxiliary Hospitals) instruction is provided for patients during convalescence in: (i.) Electrical work, fitting, &c., in connexion with electric lighting, motors, telephones, and bells; (ii.) motor driving and repairs, making of spare parts, &c.; (iii.) carpentering, including woodwork and turning.

The employment bureau of the hospital places these men as chauffeurs, garage attendants, &c., assistant electricians, or lift men in business houses, hotels, and private mansions, or in positions where a certain amount of practical knowledge of carpentering is required. Many offers of employment come from owners of private estates; men who are able to make or repair five-barred gates, doors of barns, woodwork of wells, &c., can be usefully employed on a private estate. If they are also able to run a motor to supply electricity and execute any small repairs required either to the motor or electrical fittings generally their value is correspondingly greater.

P

At these hospitals, commercial classes are also held by Clark's College in book-keeping, typewriting, shorthand, &c. The men join these classes to improve their knowledge in various directions and to assist them in the work of store-keepers, time-keepers, or similar occupations. The number who join with a view of taking up work as clerks is more limited, but is gradually increasing. If for any reason the men have not taken up a situation, they are allowed to attend free of charge classes at any of the London or provincial branches of Clark's College until placed. The wages obtained by the men when placed vary from 25s. to 40s. a week.

Although this work is valuable, yet Mr. Robert Mitchell, the director of education of the Regent Street Polytechnic, who is in charge of the training at Roehampton and Brighton, is in agreement with the principle that some of the men who have commenced training in these classes should continue their instruction after leaving the hospital at technical colleges or institutes, polytechnics, &c., in the towns where they live. He has arranged for a few men to continue training in electrical fitting at the Regent Street Polytechnic.

Training Provided by City Livery Companies.

A course of training in woodwork, &c., entirely free, is afforded at the Carpenters' Company's Technical Schools, during which the Incorporated Soldiers and Sailors Help Society agreed to find the necessary maintenance money, if required, for selected candidates during the course of instruction.¹

The Cordwainers' Company are training men in leather work. A class of 12 crippled ex-service men are being taught hand-sewn boot-making and boot-repairing at the Cordwainers' Technical College, Bethnal Green-road, London, E. The course lasts 46 weeks. The Trades Advisory Committee of the Company, before the class was started, went thoroughly into the prospects of employment, and formed the conclusion that in normal times a good workman could be sure of earning good wages at hand-sewn work.² Classes to teach the making of fancy leather goods are being conducted at the college; maintenance money is provided for both sets of men.

The Incorporated Soldiers and Sailors Help Society.

The Incorporated Soldiers and Sailors Help Society has been at work since the South African War (1899-1901). In addition to assisting over 280,000 men in various other ways, the society has established workshops at Fulham (London), Brookwood (Surrey), Colchester, Birmingham, Liverpool, Bradford, Edinburgh, and Belfast, in which skilled trades are taught to men who have been permanently disabled on active service. The trades taught include carpentering, cabinet-making, polishing, carving and gilding, framing, toy-making, basket-making, metal work, building and construction, decorating, and electrical fitting.

The society has admitted over 200 disabled men from the present war to the workshops. For every £100 received in subscriptions, they are able to teach a disabled man a trade, pay him an average wage of £1 a week for the first year and 25s. a week afterwards. The men are quite unskilled when they enter the workshops, yet soon become competent workmen. They have won the highest distinction at many international exhibitions, including the Franco-British, the Japan-British, the Festival of Empire, the Coronation, and the Imperial International. The experience of the society is that for a workshop to pay its way at least 100 men should be employed in it; this enables the work to be standardised and to be turned out in fairly large quantities.

Private Firms.

An example is set by a firm who are training crippled men in metal work; among other articles, they make the parts of chemical fire-extinguishers. The firm will employ young men under 22 years of age who have the use of both hands and arms, and is prepared to indenture them for a period of three

¹ The society made up the incomes of single men, including pension and National Health Insurance benefit if any, to £1 a week, and of married men to 25s. a week, with 2s. a week for each child, during the course of their training.

² A word of caution is necessary with regard to short courses of three months only for boot-repairing, &c. While in France the village cobbler still flourishes, in England he is practically extinct. Country people nowadays buy ready-made boots; the money to be made by repairing boots is quite inadequate for a living. For instance, in one of the largest villages in Sussex boot-mending is done by a man whose chief occupation is that of a cow-keeper; he acts as a cobbler in the evening.

years without premium at good wages, and teach them metal-working in all its branches. At the end of that period they will be guaranteed regular employment as skilled mechanics at standard wages. During the first six months the men earn £1 weekly; after this period they are paid according to their ability. Up to the present 23 men have passed through their works; but, unfortunately, as soon as they learn one branch of metal-working—e.g., filing, drilling, soldering, riveting, &c.—they leave to earn the temporary high wages obtainable elsewhere, instead of staying on to become thoroughly competent workmen.

A manufacturer of fancy-leather goods (ladies' leather belts, hand-bags, purses, note and letter cases, &c.) attends twice a week at the Roehampton Hospital with some of his staff to demonstrate the manufacture of ladies' hand-bags and to interest the men in the trade. On discharge the men are trained at the workshops of members of the National Leather Goods Association, a weekly wage of £1 being paid to commence with. The work allows of the men sitting; about three months is required to learn each section of the trade. As the fancy leather goods trade was essentially a German industry before the war, about £4,000,000 worth of goods being imported annually, the trade affords abundant scope for crippled men. The Association hopes to place 500 men.

An electric-power company are prepared to train disabled ex-service men as sub-station attendants or switchmen. So far they have only one disabled soldier suffering from a smashed foot, necessitating the use of a crutch, at work (as a sub-station attendant); another discharged on account of a wound in the arm is about to commence duties. In some electric-power works, especially main-power stations, in addition to operating the switches, the men have heavier duties to perform, such as cleaning, overhauling and adjusting plant. The electric power company in question, however, consider that in stations where large units are installed more than one man should be employed on the shift when the heavy cleaning work is undertaken, men with dissimilar injuries being selected to supply one another's deficiencies. The work of overhauling and adjustment should be carried out by workmen with sound limbs. The requirements of the company are met if the disabled man can get about his work reasonably well and if he is intelligent enough to act promptly in emergencies.

Agriculture.

The Departmental Committee on the land settlement for ex-service men, presided over by Sir Harry Verney, stated that they had no doubt that the openings for disabled men in agriculture were considerable, and were of the opinion that such men could carry on poultry, pig, and calf-rearing, fruit cultivation, bee-keeping, home industries, small dairy farming, and mixed production on small holdings.

A number of disabled men are receiving training in horticulture and other work at the Holmes Chapel College of Agriculture, Cheshire, in accordance with the arrangements made by the Board of Agriculture. The men are instructed, boarded, and lodged free of charge; no deduction of any sort is made from their pension. A three months' course enables men who have had considerable agricultural experience before joining the service to obtain satisfactory employment on farms; such men take the course of training to obtain knowledge of a special branch of the work, such as cheese-making. The short course also serves to indicate those men whose work and character are sufficiently satisfactory to warrant the expenditure on a further nine months' course of training.

ABILITIES OF MEN WITH VARIOUS LESIONS.

It is impossible to lay down any hard-and-fast rules as to the occupations available for men with certain defects; the ingenuity and perseverance of some of the disabled men are such that they manage to work at trades most people would consider them unfitted for. For instance, I have seen men with one sound arm and the stump of the other arm working at electric fitting, and a man with his right arm amputated near the shoulder-joint carrying out all the repairs required to the agricultural machines of a large farm.

The man who has lost an arm is, of course, much more limited in his choice of a trade than the man who has lost one or both legs. At the Lyons Ecole, the occupations found most suitable for one-armed men are toy-making and various parts of the book-binding trade. At Montpellier

the following occupations are being taught to men who have lost, or lost the use of, an upper limb.

| Occupation. | Nature of the Patients' Lesions. |
|--|---|
| Wood-turner | Amputation of left forearm. Amputation of right forearm. Injury to right hand, two fingers amputated, other digits ankylosed. Ankylosis of right shoulder. Ankylosis of left elbow. Musculo-spiral paralysis (2 patients). |
| Tailor | Ankylosis of left elbow. Paralysis of right arm. Ankylosis of right elbow. Ankylosis of right elbow and wrist. Paralysis of right radial nerve. |
| Boot-maker | Ankylosis of right shoulder. |
| Ajusteur - mécanicien (Skilled mechanic). | Amputation of right arm and left thigh. Amputation of right arm and thigh. |

At Bordeaux, of 49 pupils learning manual occupations, 28 had sustained an injury to the arm; of these, 10 were learning basket work.

At Bourges, where drawing is taught to men whose arms have been amputated, pupils who have followed other occupations and have not previously been taught drawing except at an elementary school, have been taught to make plans, &c., sufficiently well to justify their employment in departments analogous to our Board of Works and borough surveyors' departments. Needless to say, the aim of the school is not to make artists but capable draughtsmen. The school authorities point out the openings for men who can learn to draw—designers of lace, engravers, lithographers, ticket writers, sign writers, &c.

At St. Étienne the men learning horticulture, kitchen gardening, gardening, and agriculture are, for the most part, suffering from ankylosis of an arm; two have lost an arm.

In the United Kingdom, telegraphy and telephony apparently offer possibilities for one-armed men, provided that the arrangements can be made for their obtaining occupations in the General Post Office after training.

Although manual pursuits are preferable, clerical work will be an occupation most suitable for a large number of men with loss of, or an injury to, the arm. The handling of heavy ledgers is more difficult for one-armed men, but this difficulty has always been overcome by the employers of men from Roehampton Hospital. At this institution, men who have lost their right arm have acquired in a short time an amazing degree of efficiency both in longhand and shorthand writing; they can, if they will take the trouble, learn to write well with the left hand. Typewriting can be done with one hand; if the patient can use his stump or an appliance fitted on to it to depress the space bar at the end of each word, he will be able to typewrite with practice at quite a satisfactory speed.

Very few trades are absolutely closed to men who have lost their legs. Some of the disabled men express the fear that they will not be able to undertake work involving long standing; possibly this fear is justified in the case of heavy men with an amputation near the hip. Dr. Carle of the Lyons École considers wood-work, especially joinery, unsuitable for men with an amputation of the left leg much above the knee, but I have seen a fair number of men with amputations near the left hip carrying out this work, including planing, which is supposed to be the special difficulty. The experience of the Soldiers and Sailors Help Society on the effect of the loss of a leg, is, of course, valuable. They consider that "the loss of one leg does not debar a man from being quite as useful as he would be with two legs, provided a little care is taken with him in the early stages; and we consider that if we were to take two men, the one having all his limbs and the other minus a leg, we should be more successful with the man minus a leg than with the able-bodied one, for this reason, that the man with the one leg realises that he is not quite so useful as the other man, and therefore lays himself out to be as useful as he can possibly manage to be. We can arrange suitable work for men who have lost both legs; it is only a matter of getting the man to his bench or into his chair each morning. The loss of a leg and arm is a little more difficult, but for even cases such as these we can find plenty of work."

A large sphere of semi-skilled labour exists in factories where machines are employed to carry out one particular

operation. Even a one-armed man is able to use such various machines as circular saws, band saws, drills, &c.; the man with injuries confined to the legs will experience very little difficulty in working light machines. The necessary training for such work can only be obtained in the factories of the employers; fortunately many employers have expressed their opinion to the War Pensions Statutory Committee that their foremen will be willing, and in fact anxious, to teach the disabled men the use of these machines.

The Committee appointed by the Home Secretary to consider the matter have pronounced the driving of public vehicles such as motor-cabs, motor-omnibuses, and tramway-cars unsuitable for men who have suffered the loss of an arm, hand, leg, or foot. They point out that the best of artificial limbs are liable to fracture; such an event happening at an emergency might produce serious results. The loss of an eye is also considered to debar the man from such employment. In the case of injury to one eye, provided the other eye is sound and the injured eye retains fair vision, they consider a licence might be granted, each case being, of course, decided on its merits.

As regards other minor disabilities, such as loss of one or more fingers, or other damage to the hands, limitation of movements of joints of the upper or lower extremities, or shortening of the lower extremities, and the results of injuries to nerves of limbs, they recommend that the existing practice continue to be followed, and that each case be dealt with on its merits at the discretion of the Commissioner of Police with, in doubtful cases, a power of reference to a special medical referee.

Nothing prevents the employment as garage attendants of men debarred as above from becoming drivers of public motor vehicles, but often such attendants are called upon from time to time to act as drivers. No difficulty would arise with regard to standing engagements providing the consent of the hirer were obtained to the employment of such a man as driver, but casual hirings where the condition of the man was not known to the hirer would probably not be permitted by the police authorities.

ARTIFICIAL APPLIANCES FOR THE ONE-ARMED.

At Montpellier considerable attention is being paid to the designing of artificial appliances to assist men suffering from loss of or injury to the arm. The appliances serve to hold various tools in the desired manner; they are made by crippled men and are tested and used by the crippled men working in other sections of the school.

A grip has been designed to hold a tool in any position; a modification serves to hold the instruments used in drawing and engraving. A simpler modification enables a mechanic to hold his tools in the three positions in which the screw-driver, hammer, and file respectively are used. To enable wood-turners to drill a hole, &c., the school has devised a socket fitted with springs to grasp the head of the tool firmly.

M. Bessat has designed a gauntlet³ for the use of men with musculo-spiral paralysis. M. Dronsart, the director of the technical work of the school, states that the gauntlet has enabled a carpenter to resume his former trade, and two pupils, who are learning designing, to use their instruments as efficiently as their fellow-pupils with the use of two hands.

For digging a long socket and stirrup have been combined. The socket fits over the upper part of the shaft of the spade, of which the ordinary handle is omitted. Raising and lowering the spade is permitted by a joint at each side of the socket, where the bar of the stirrup passes through it in the median plane above the top of the shaft of the spade.

At Lyons the one-armed men engaged in the stitching of books and the putting on of the covers are enabled to use their stump to hold the leaves or the cover by the use of an artificial appliance to which is fitted at the end of a rod a small wooden block surmounted by a clip; between the clip and the block is placed the article it is desired to hold. In another apparatus the movements of the chest wall are utilised to open and close a grip without the intervention of the sound hand. The school is also endeavouring to modify the classical hook and ring fitted to artificial arms so as to enable the men to hold more firmly the handles of their tools. But Dr. Carle frankly owns that he has paid unexpected visits

³ A simple apparatus for use in cases of musculo-spiral paralysis, patented in Great Britain, is described and figured in THE LANCET, vol. II., 1916, p. 624.

to the workshops and found that a workman provided with a carefully devised artificial implement has placed it on the table and is working away with his sound arm and stump. Dr. Bourrillon, of the St. Maurice Institut Professionel, also says—

"Je n'ai pas encore jusqu'ici rencontré d'appareils prothétiques qui puissent rendre de réel service dans un apprentissage quelconque."

And again—

"Je ne crois guère à l'utilisation, au point de vue professionnel, des appareils de prothèse des membres supérieurs. Ce ne peut être, à mon avis, que dans des cas très restreints que ces appareils peuvent avoir une sérieuse portée pratique. Nous n'employons donc dans nos ateliers que des moyens simples que les amputés trouvent eux-mêmes la plupart du temps, pour les aider dans l'exercice de leur profession, et il n'existe aucun dessin de ces dispositifs qui varient beaucoup suivant chaque individu."

In my experience simple appliances are of undoubted service, especially in the working and minding of machines. A one-armed man working a drill at a workshop of the Soldiers and Sailors Help Society made himself an arrangement of wire, which he attached to the stump of his arm to enable him to use it for pulling the lever into position for the drill to take effect. An artificial appliance is of considerable help in clerical work; it enables a man to hold a ruler, to steady a page, to depress the space bar of a typewriter, &c.

Various modifications of apparatus will be doubtless forthcoming and prove useful. The London School of Weaving has brought out a loom for the use of cripples who are unable to use the treadles of an ordinary hand-loom. This loom can be worked by a person with one arm. The stitching pad can be used by the man doing boot-work when he has not a sound knee to press against.

MEN NOT DESIROUS OF LEARNING SKILLED TRADES.

The Corps of Commissionaires with its London headquarters and branches in most of the largest cities of the United Kingdom is probably the largest organisation which deals with the discharged ex-service man not desirous of taking up a skilled trade. All men who have served in any branch of His Majesty's Regular Forces are eligible, provided they come up to the requisite standard of health, physique, education, and can produce a regimental discharge satisfactory as regards character. Men from the Auxiliary Forces are admitted on the same terms as other soldiers if discharged on account of wounds received in action.

The total strength is about 4500, including nearly 2000 serving with the colours; from May, 1915, to May, 1916, 277 men have been admitted to the corps, 127 of whom were discharged for wounds. Many of these latter have lost a limb, all of them have received severe injuries. At present the corps have many more applications for men from employers than they can deal with. Up to the present Major Fielden, commanding the London division of the corps, has had no difficulty in placing men who have lost an arm or the use of an arm; the placing of men who have lost a leg is more difficult. Commissionaires are employed either temporarily or permanently, part-time or whole-time as watchmen (by day or night), clerks, time- and gate-keepers, messengers, caretakers, gymnastic and drill instructors, grooms, boatmen, and porters. Some of these occupations are obviously fitted for crippled men. The average weekly rate of wages for commissionaires in London and other large cities is about 30s., in smaller towns about 28s., but men with superior physical or educational qualifications earn more.

Sir Frederick Milner has pointed out the work available in large stores, shops, and hotels for limbless men; they are capable of working the lifts, acting as attendants in cloak-rooms, &c. Doubtless similar positions and posts as park-keepers, &c., in Government and municipal departments will be filled eventually by ex-service men.

The training provided in England up to the present has been for disabled soldiers with an elementary education, but disabled men of superior education also require provision. The engineering and chemical industries in England are not only in need of men who have had technical training, such as is afforded at the Manchester School of Technology, but they recognise the need and are ready to pay them an adequate salary. It is to be hoped that in the immediate future scholarships adequate in amount will be founded to enable suitable ex-service men to take up such training.

THE RELATION OF THE ENTEROCOCCUS TO "TRENCH FEVER" AND ALLIED CONDITIONS.

By THOMAS HOUSTON, B.A., M.D. R.U.I.,
MAJOR, ROYAL ARMY MEDICAL CORPS (TEMP.);

AND

JOHN M. McCLOY, M.D. BELF., D.P.H.,
CAPTAIN, ROYAL ARMY MEDICAL CORPS (TEMP.).

THE bacteriological investigations carried out in the St. John Ambulance Brigade Hospital have revealed the presence of the enterococcus in numerous diseased conditions, and in the course of routine work evidence has been accumulated which indicates that this coccus is an infective agent in many of the cases admitted to the medical and surgical wards. This striking feature of the bacteriology of the present war has induced us to publish in a preliminary and incomplete form some of the work which has been done in this laboratory on the subject. The attention of other workers may thus be directed to the organism, and if the conclusions arrived at in this paper regarding it are confirmed efforts may be made to prevent or deal with what appears to be a very prevalent and serious infection.

The frequency with which the enterococcus is found infecting wounded men suggested the possibility of it being a cause of illness in the unwounded living under the same conditions in the trenches. To ascertain if this be so was the main object of the investigations outlined in this paper, and it would appear from what follows that the micro-organism may cause a great number of cases of continued, irregular, and intermittent fever that have been described under the title of "trench fever," that it is the infective agent in many cases of "myalgia," and that numerous cases of short fever diagnosed as "influenza" are attributable to it. The scope of this inquiry is very large, as may be inferred from the fact that out of a total number of 2200 medical cases 18 per cent. were "myalgia," 10.5 per cent. indefinite fever, 3 per cent. pleurisy, and 3 per cent. rheumatic fever and arthritis. Owing to the exigencies of a base hospital it was impossible to investigate fully more than a limited number of these cases.

The cases in which infection with the enterococcus was found do not conform to a disease of special type, having characteristic clinical features. Most of the cases, however, have certain symptoms in common, notably sudden onset with fever, headache often orbital, loss of appetite, furred tongue, and pains in the back and lower limbs, especially in the shins. During the course of the illness the patients generally suffer from constipation, bursts of profuse perspiration are of frequent occurrence, and mental depression is often present. The variations in the clinical manifestations are well exemplified by the number of different diagnoses with which the cases have been labelled. This diversity also makes their classification difficult, but for the purposes of description they have been arranged in the following groups, the members of each group bearing a close relationship to each other. Some of the cases in one group will be found resembling cases in another, thus linking the groups together.

1. Septicæmia Group (Table I.).

The cases of septicæmia, charts of which follow, exhibit one period of continuous fever lasting from 11 to 30 days. The onset is almost invariably sudden, with headache, rise of temperature, shivering—sometimes definite rigors and nausea—occasionally vomiting, and general aching pains. The patient when admitted to the hospital may be severely ill, having a temperature from 102° to 104° F., and exhibiting an appearance not unlike a case of typhoid in the early stage of the disease. The tongue is furred, there is generally some swelling or tenderness of the abdomen, and the spleen may be enlarged. The appetite is lost and constipation is almost invariably present. The skin is moist, there may even be profuse sweating. The pulse compared with the temperature is slow. After a few days the initial pains disappear, but the headache is persistent and severe. Herpes may appear on the lips during the course of the illness. The motions are highly offensive. When the temperature has become normal convalescence as a rule is rapid, and there is no recurrence of the pains which accompany the onset; but in a few cases of this type pains

TABLE I.—SEPTICÆMIC TYPE.

| No. | Original diagnosis. | Prominent symptoms. | Type of fever. | Evidence of infection. | Vaccine used. | Effect of vaccine. | Remarks. |
|-----|---------------------|--|----------------------|---|---------------|--|---|
| 1 | Pericarditis. | Sudden onset with vomiting. Classical signs of pericarditis confirmed by radiogram. | Continuous, 17 days. | Enterococcus in urine. Opsonic indices. | Auto-genous. | Fall of temperature and general improvement. | Recovery very rapid. |
| 2 | Septicæmia. | Sudden onset with headache, Headache, malaise, abdominal distension, albuminuria. | Continuous, 11 days. | Enterococcus in blood and urine. | None. | — | Severely ill for 3 days. Recovery rapid. |
| 3 | Slight G.S.W. | Sudden onset with diarrhoea. | Continuous, 12 days. | Enterococcus in blood. | " | — | Case of pyrexia occurring in surgical case. |
| 4 | Influenza. | Sudden onset with headache. Lumbar pain, pain in shins, cough, congestion of bases of lungs, spleen palpable. | Continuous, 30 days. | Enterococcus in urine and sputum. | Auto-genous. | Febrile and focal reaction. | — |
| 5 | Myalgia. | Sudden onset with headache and shivering. Lumbar pain, pain in shins, constipation, furred tongue, abdominal tenderness, rigors, frequency of micturition, restlessness. | Continuous, 17 days. | Enterococcus in urine. | " | Slight febrile and focal reaction, nausea. | Pains in lower limbs became more severe after temperature became normal. |
| 6 | P.U.O. | Sudden onset with headache, vomiting, and pain in limbs. Lumbar pain, pains in shins and ankles, spleen palpable. | Continuous, 12 days. | Enterococcus in blood. | " | Febrile and focal reaction. | This patient had a second pyrexial period of 2 days after 3 days normal temperature.] |
| 7 | " | Sudden onset with headache, giddiness, pains in knees and shins. Furred tongue, drowsiness, slight bronchitis. | Continuous, 10 days. | Enterococcus in urine. | " | " | — |
| 8 | " | Gradual onset with headache and general pains. Abdominal pain, furred tongue, slight bronchitis, roseolæ eruption on chest, arms, and back. | Continuous, 28 days. | Enterococcus in blood. | " | Febrile and general reaction. | Pains in lower limbs on admission, disappeared in a day or two, and returned after temperature became normal. |
| 9 | Myalgia. | Gradual onset with headache and pains in back and legs. | Continuous. | — | Stock. | " | Had dysentery in Gallipoli. During his convalescence he developed his first attack of "myalgia." Present attack some months afterwards. |

TABLE II.—"TRENCH FEVER" TYPE.

| | | | | | | | |
|----|---------------|---|---|--|--------------|-----------------------------|---|
| 10 | Slight G.S.W. | Sudden onset with headache and malaise. | Intermittent 3 febrile periods. | Enterococcus in blood. | None. | — | The illness occurred after the wound had healed. |
| 11 | " | Sudden onset with headache, giddiness, and pains in lower limbs. | " | Enterococcus in urine. | Stock. | Febrile and focal reaction. | The illness occurred after the wound had healed. |
| 12 | Trench fever. | Sudden onset with headache, pain in lumbar region and legs. Herpes. | " | " | " | " | This patient was very ill and had several febrile attacks before admission to hospital. |
| 13 | Myalgia. | Sudden onset with headache, cough, general pains, abdominal tenderness, tenderness of shins. | " | Enterococcus in blood (twice) and in sputum. | Auto-genous. | " | — |
| 14 | Slight G.S.W. | Sudden onset with headache, vomiting, lumbar pains, and pains in shins. | " | Enterococcus in blood. | " | " | The illness occurred after the wound had healed. |
| 15 | Trench foot. | Sudden onset with headache, pain in shins and feet. | " | — | Stock. | " | — |
| 16 | P.U.O. | Gradual onset with headache and malaise. Suddenly became much worse with cough, vomiting, pains in chest and stomach. | Intermittent 2 febrile periods. | Enterococcus in blood. | Auto-genous. | " | Some pains in shins occurred after a dose of vaccine. |
| 17 | Myalgia. | Sudden onset with headache, pain in legs, abdominal tenderness. | Intermittent 3 febrile periods. | — | Stock. | " | — |
| 18 | " | Sudden onset with headache, malaise and fever. Lumbar pains, pains in knees and shins. | Intermittent 5 febrile periods. | — | " | " | Had pains in knees for 3 months previously. |
| 19 | " | Sudden onset with headache, shivering, and general pains. Pains in legs, especially shins. | Intermittent 2 febrile periods after admission. | Enterococcus in urine (twice). | Auto-genous. | " | — |

G.S.W. = Gunshot wound.

P.U.O. = Pyrexia of unknown origin.

TABLE III.—"MYALGIC" TYPE.

| No. | Original diagnosis. | Prominent symptoms. | Type of fever. | Evidence of infection. | Vaccine used. | Effect of vaccine. | Remarks. |
|-----|-----------------------|--|----------------|----------------------------------|--------------------------------------|---|--|
| 20 | Influenza. | Sudden onset with headache, pain and weakness in legs. Gastric disturbance and tenderness of shins. | Irregular. | Enterococcus in blood and urine. | Auto-genous. | Febrile and focal reaction. | Six days' pyrexia occurred 3 weeks after admission. |
| 21 | Trench foot. | Sudden onset with pain and swelling of feet and left hand. | " | Enterococcus in urine. | " | " | This case was characterised by some swelling of knee and wrist joints. |
| 22 | Myalgia. | Gradual onset with pain in right knee, ankles, and feet. | Afebrile. | " | " | Temporary relief after each inoculation. | Previous history of pains in limbs. |
| 23 | Peritoneal adhesions. | Sudden onset with headache, pains in knees and shins. Herpes. | Irregular. | Enterococcus in blood. | " | Febrile and focal reaction. | The myalgia developed after 5 days in hospital. |
| 24 | Myalgia. | Sudden onset, with pains in back and lower limbs. | " | Enterococcus in urine. | Mixed streptococcal and autogenous | No effect from either vaccine. | There was some swelling of right great toe. History of gonorrhoea. |
| 25 | " | Sudden onset with pain in shoulders, back, and shins. Frequency of micturition. | " | " | Auto-genous. | No effect. | " |
| 26 | " | Sudden onset with headache, pain in back and legs. | Afebrile. | " | " | Febrile and focal reaction. | " |
| 27 | " | Gradual onset with headache, pain in back and legs. Frequency of micturition. | " | " | " | " | " |
| 28 | " | Sudden onset with shivering, headache, pain in back and legs. | " | " | " | " | " |
| 29 | " | Sudden onset with loss of power and sensation from knees downwards. Pain in groin and erythema of feet. | " | " | " | Focal and general reaction. | " |
| 30 | Fever. | Sudden onset with headache, general pains, and diarrhoea. Pain and swelling of shoulder, feet, and legs. Frequency of micturition. | " | " | " | Febrile and focal reaction. | Some swelling of joints occurred in this case. History of rheumatism. |
| 31 | Myalgia. | Sudden onset with vomiting and diarrhoea. Pain in back and lower limbs. | Irregular. | " | " | Fall of temperature and general improvement. | " |
| 32 | " | Sudden onset with headache, pains in arms, legs, back, and stomach. Frequency of micturition. | " | " | Stock. | Febrile and focal reaction. | " |
| 33 | " | Gradual onset with shivering and pains in shoulders, arms, and legs. Tenderness of shins. | Afebrile. | " | Mixed streptococcal and auto-genous. | Mixed streptococcal had no effect. Temporary relief after each inoculation of autogenous. | " |
| 34 | " | Sudden onset with headache and pain in back and legs. | Irregular. | " | Auto-genous. | Marked improvement after each inoculation. | " |
| 35 | " | Sudden onset with headache and pain in back and legs. | " | " | " | Improvement after each inoculation. | " |
| 36 | P.U.O. | Sudden onset with headache, rigors, and pain in back, arms, and legs. Frequency of micturition. | Irregular. | " | Stock. | Febrile and focal reaction. | " |
| 37 | Colitis. | Gradual onset with headache and malaise. Pains in shoulders, knees, and ankles. Abdominal pain. Much mucus in stools. | " | " | Auto-genous. | " | Note abdominal symptoms. |
| 38 | Influenza. | Sudden onset with shivering, headache, pain in back, arms, and legs. Marked tenderness of shins. | " | " | " | Slight general reaction. | Vaccine treatment in this case was disappointing. |
| 39 | Myalgia. | Gradual onset with pains in legs. Pains in knees and arms. Tender ness and pains in shins. | " | " | " | Febrile and focal reaction. | Previous history of rheumatism. Constipation was absent in this case. An administration of a purgative produced a sharp rise of temperature. |
| 40 | Meningitis? | Sudden onset with headache and intense pain in spine. Extreme tenderness of muscles of back and legs. | " | Enterococcus in blood. | Stock. | " | Patient was seriously ill, and at first appeared like a case of meningitis. |

FIG. 1.—Charts of Septicæmic Type (Cases 1-9).

The arrows indicate the inoculation of vaccine.

- 1.—Septicæmic type. Diagnosis—Pericarditis. 24/9/15: Enterococcus isolated from urine. 26/9/15: Opsonic index—morning 0.4, evening 0.7. 27/9/15: First and second inoculations, 5 millions each.
- 2.—Septicæmic type. Diagnosis—Septicæmia. 27/11/15: Enterococcus isolated from blood and urine.
- 3.—Septicæmic type. Diagnosis—Slight G.S.W. 23/4/16: Enterococcus isolated from blood.
- 4.—Septicæmic type. Diagnosis—Influenza. 21/3/16: Enterococcus isolated from urine and sputum. 25/3/16: First inoculation, 2 millions. 30/3/16: Second inoculation, 2 millions. 3/4/16: Third inoculation, 3 millions. 10/4/16: Fourth inoculation, 3 millions.
- 5.—Septicæmic type. Diagnosis—Myalgia. 4/2/16: Enterococcus isolated from blood. 19/2/16: Opsonic index—1.7. 14/2/16: First inoculation, 2½ millions. 19/2/16: Second inoculation, 2 millions. This patient had "myalgic" pains for three weeks after his temperature became normal.
- 6.—Septicæmic type. Diagnosis—P.U.O. 25/3/16: Enterococcus isolated from blood. 25/3/16: 2 c.c. citrated blood from the patient were injected intravenously into a rabbit; 12 days later the animal developed stiffness and tenderness of its limbs. 25/3/16: First inoculation, 2½ millions, stock. 3/4/16: Second inoculation, 1½ millions, autogenous. 13/4/16: Third inoculation, 2½ millions. 18/4/16: Fourth inoculation, 2½ millions.
- 7.—Septicæmic type. Diagnosis—P.U.O. 22/1/16: Enterococcus isolated from urine. 25/1/16: First inoculation, 5 millions. 28/1/16: Second inoculation, 10 millions. 1/2/16: Third inoculation, 20 millions. 5/2/16: Fourth inoculation, 5 millions. A large dose of vaccine gave the patient a severe headache lasting for one week.
- 8.—Septicæmic type. Diagnosis—P.U.O. 1/5/16: Enterococcus isolated from blood. 4/5/16: First inoculation, 1 million. 8/5/16: Second inoculation, 1½ millions. 13/5/16: Third inoculation, 1½ millions. 19/5/16: Fourth inoculation, 2 millions.
- 9.—Septicæmic type. Diagnosis—Myalgia. Enterococcus not found. 30/4/16: First inoculation, 60 millions stock staphylococcus vaccine. No effect produced. 3/5/16: Second inoculation, 60 millions staphylococcus vaccine and 1½ millions stock enterococcus vaccine. Reaction produced. 14/5/16: Third inoculation, 2 millions enterococcus vaccine. Reaction produced. 19/5/16: Fourth inoculation, 90 millions staphylococcus vaccine. No reaction produced. This patient suffered from furunculosis in addition. The case illustrated the use of vaccines in diagnosis.

FIG. 2.—Charts of "Trench Fever" Type (Cases 10-15 and 17-19).

- 10.—"Trench fever" type. Diagnosis—Slight G.S.W. 6/4/16: Enterococcus isolated from blood.
- 11.—"Trench fever" type. Diagnosis—Slight G.S.W. 1/4/16: Enterococcus isolated from urine. 27/3/16: First inoculation, 2½ millions stock.
- 12.—"Trench fever" type. Diagnosis—"Trench fever." 23/4/16: Enterococcus isolated from urine. 7/4/16: First inoculation, 2½ millions stock. 12/4/16: Second inoculation, 3 millions. 19/4/16: Third inoculation, 1 million. 26/4/16: Fourth inoculation, 1½ millions. In this case it would appear as if the vaccine determined two of the pyrexial periods.
- 13.—"Trench fever" type. Diagnosis—Myalgia. 23/4/16: Enterococcus isolated from blood. 28/4/16: Enterococcus isolated from blood, also from sputum. 28/4/16: 2 c.c. citrated blood from patient were injected intravenously into a rabbit. Eight days later the animal developed stiffness and tenderness of its limbs. 2/5/16: First inoculation, 1 million. 10/5/16: Second inoculation, 1½ millions. 14/5/16: Third inoculation, 2 millions.
- 14.—"Trench fever" type. Diagnosis—Slight G.S.W. 30/4/16: Enterococcus isolated from blood. 14/5/16: Opsonic index, 1.2. 8/5/16: First inoculation, 1½ millions. 12/5/16: Second inoculation, 1½ millions. 17/5/16: Third inoculation, 2½ millions.
- 15.—"Trench fever" type. Diagnosis—"Trench fever." Enterococcus not found. 30/11/15: First inoculation, 5 millions, stock. 7/12/15: Second inoculation, 2½ millions. The third pyrexial period seemed to be determined by the vaccine.
- 17.—"Trench fever" type. Diagnosis—Myalgia. Enterococcus not found. 15/3/16: First inoculation, 2½ millions, stock. 29/3/16: Second inoculation, 5 millions.
- 18.—"Trench fever" type. Diagnosis—Myalgia. Enterococcus not found. 23/5/16: First inoculation, 1 million, stock. 29/5/16: Second inoculation, ½ million. 2/6/16: Third inoculation, 1 million. 6/6/16: Fourth inoculation, 1 million. In this case the vaccine had a decided effect upon the temperature and general condition of the patient. The first dose was followed by a rise of temperature and aggravation of the symptoms. After the second dose the temperature fell to normal and the pains disappeared. The third and fourth doses produced slight rises of temperature and transient return of the pains.
- 19.—"Trench fever" type. Diagnosis—Myalgia. 22/4/16: Enterococcus isolated from urine. 24/4/16: Enterococcus isolated from urine. 1/5/16: First inoculation, 2½ millions. 9/5/16: Second inoculation, 2½ millions. 16/5/16: Third inoculation, 2½ millions.

of a myalgic character may develop and a sudden rise of temperature may occur. All the cases of this group were fully investigated for possible infection with typhoid and paratyphoid organisms, and the results of these investigations were uniformly negative. That the enterococcus was the infective agent in these cases appears from the following. It was found in the blood in 5 cases, and in 4 it was isolated from the urine, and in 1 case it occurred in the sputum. In 7 of the cases treated with vaccines the effects were quite definite—namely, there was reaction followed by improvement. (See Fig. 1.)

2. "Trench Fever" Group (Table II.).

This group contains cases of a similar character to those described as "trench fever" by various writers. McNee, Renshaw, and Blunt divide cases of this nature into two clinical types: "(a) a short fever of about a week's duration, followed frequently after a few days by a short single relapse, and (b) a longer illness characterised above all by the number, character, and periodicity of the relapses"—and give reasons for believing that both are due to the same infective agent. Although many of our cases could be placed in one or other of these divisions, some do not accurately conform to this simple classification. The onset is abrupt, as in the septicæmic type, and the early symptoms are similar but of rather less severity. The fever is not continuous, but intermittent in character. There may be only one febrile period or as many as five, possibly more. The periods of pyrexia are of brief duration, usually two or three days; but the initial period, rarely seen in a base hospital, may be longer. The febrile periods are characterised by headache, loss of appetite, sweating, and pains in the back and lower limbs. The pains are often especially severe in the shins and associated with marked tenderness. During the apyrexial periods pains are usually absent, but in some cases they persist. A few cases have been observed in which pains are absent during the entire course of the illness, the only symptoms being intermittent fever, headache, and malaise. Bacteriological investigation of these cases demonstrated the presence of the enterococcus in the blood of 3 of the patients, in the urine of 3, and in the sputum of 1, while in the remaining 3 the organism was not found. All the cases in this group except No. 10 were treated with enterococcus vaccine and definite reactions were observed in every instance. (See Fig. 2.)

3. "Myalgia" Group (Table III.).

This group contains the largest number of cases of enterococcal infection which have been investigated. The majority of these patients never suffered from any rheumatic condition before. The onset and initial symptoms are the same as in the previous groups. There is, however, only one period of pyrexia, lasting from a few days to a week. These patients do not, as a rule, reach the base hospital until the fever has almost or completely subsided. The most striking feature in this class of case is the persistence of pains during the afebrile period. The pains are usually localised, being confined to the lumbar region and lower limbs, the shins especially are painful and tender. Periods of exacerbation in the intensity of the pains occur; they are also usually worse at night and in cold, damp weather. During one of these periods there may be a sudden rise of temperature, which suggests a close relationship between this group and those previously described. The pains may persist for several weeks after the temperature has returned to normal. Three charts which show some divergence from the usual apyrexial character are given. The enterococcus was found in both the blood and urine in 1 case, in the blood of 2, and in the urine of the remaining 18 cases. All of the patients were treated with vaccines, usually autogenous, and a study of the results gave additional evidence of infection with this micro-organism. (See Fig. 3.)

Bacteriology.

The enterococcus is a constant inhabitant of the normal bowel. It differs from all other streptococci by the ease with which it is grown on ordinary laboratory media and by its greater power of resistance—that is, cultures of it survive longer and are more difficult to kill. In preparations made from pus it appears almost invariably as a lanceolate diplococcus. It stains easily and is Gram-positive. It grows well on all ordinary laboratory media under both aerobic and anaerobic conditions.

On agar it forms a fine growth, not unlike that of streptococcus pyogenes, but the individual colonies are larger and more opaque, and when a heavy implantation is made there is a greater tendency to produce a uniform film. On trypsin agar, introduced by Douglas, it grows luxuriantly, resembling cultures of staphylococci on ordinary agar, and its growth is much more rapid than that of an ordinary streptococcus, being distinctly visible in four or five hours. On gelatin, at room temperature, it forms a white growth in 24 hours and does not liquefy the medium. On Conradi-Drigalski's medium it grows well; in 24 hours the size of the

FIG. 3.—Charts of Myalgic Type (Cases 20, 23, and 40).

20. "Myalgic" type. Diagnosis—Influenza. 15/2/16: Enterococcus isolated from blood and urine. 15/2/16: 2 c.c. citrated blood from patient were injected intravenously into a rabbit; 18 days later the animal developed pain and stiffness of its limbs and neck. 16/2/16: Oponic index—morning 1.2, evening 1.5. 23/2/16: First inoculation, 2½ millions.

23. "Myalgic" type. Diagnosis—Peritoneal adhesions. 24/4/16: Enterococcus isolated from blood. 1/5/16: First inoculation, 2½ millions. 9/5/16: Second inoculation, 2½ millions. 16/5/16: Third inoculation, 2½ millions.

40. "Myalgic" type. Diagnosis—"Meningitis"? 28/5/16: Enterococcus isolated from blood. 3/6/16: First inoculation, 1 million. 11/6/16: Second inoculation, 1 million. 18/6/16: Third inoculation, 1 million.

individual colonies is intermediate between those of bacillus coli and an ordinary streptococcus, and the medium becomes red. In cultures on this medium, examined microscopically, the organism is found almost exclusively as a lanceolate diplococcus, short bacillary forms are also seen, but chain formation is absent. This medium is of great value in isolating the enterococcus from pus and other material containing a variety of bacteria, as it inhibits the growth of many organisms, including staphylococci. In broth the enterococcus grows well, producing a uniform turbidity, and forming comparatively short chains and diplococci. In milk it grows fairly well, assuming chiefly the diplococcal form, and the medium is coagulated in about three days. The character of its growth in serum has been fully described by Sir Almroth Wright, who has pointed out its serophytic properties. Its action on the following sugars—the only ones available—was tested. It rapidly ferments glucose, lactose, and saccharose, more slowly salicin; no change in mannite could be demonstrated in one week.

Its resistance to heat is remarkable. A thick emulsion of the coccus in broth or physiological saline solution contained in a test tube was found in numerous experiments to be alive after an exposure for one and a half hours to a temperature of 55° C. The heat-resisting properties of the enterococcus formed the basis of a method for isolating the organism from pus, faeces, and sputum. An emulsion of any of these materials in broth was incubated in a test-tube at 37° C. for several hours, and then exposed to a temperature of 55° C. for a period of from half an hour to one hour in the vaccine steriliser. Loopfuls of the emulsion were then plated out on Conradi-Drigalski's medium and the plates incubated for 24 hours.¹ Cultures of the coccus are emulsified with great ease in physiological saline solution, and in this respect the organism contrasts markedly with other streptococci.

¹ This method was applied to samples of mud obtained from the boots and clothing of patients on admission to hospital, and the enterococcus was isolated without difficulty from all the specimens examined.

To establish the relation of an organism recovered from the body to a diseased condition is one of the most important and most difficult problems of modern medicine. A number of the methods which have been devised for this purpose have been applied to the enterococcus. Many experiments were made with different sera in order to ascertain whether the character or rate of growth of the coccus in serum would form a reliable means of distinguishing infected from non-infected persons. It was found, as Wright has pointed out, that differences do occur; in the serum of some cases of infection the coccus grew more quickly and in others more slowly than in normal serum, but the differences were not sufficiently constant or sharply marked to render the method of general application in the diagnosis of infection.

Experiments in agglutination were frequently done. The coccus was found to be agglutinated to a greater extent by infected than by normal serum, but the differences were too small to be of definite value, and this method was also abandoned. Complement deviation tests received a limited trial, but neither did they furnish satisfactory criteria. Evidence of infection was therefore based upon the following—the isolation of the organism from various sources, such as blood, wounds, urine, sputum; the results of opsonic index determinations; and the effect of vaccines used as diagnostic and therapeutic agents.

1. *The isolation of the organism from various sources.*—(a) *The blood.*—As a rule, 20 c.c. of blood were collected aseptically from a vein in the arm. This blood was distributed as follows: 5 c.c. in a flask containing 50 c.c. broth, 5 c.c. in a flask containing 50 c.c. broth and 10 c.c. bile, and 10 c.c. in a test-tube containing $\frac{1}{2}$ c.c. of Allen and Hanburys' compound solution of trypsin. These were incubated and examined from day to day for five days by film and plate methods. The following table gives the results of all blood cultures done in the hospital up to the present date:—

| | | | |
|-----------------------|----|----------------------------|-----|
| Sterile | 85 | Tetragenus | 3 |
| Enterococcus | 20 | Bacillus: Non-lactose fer- | 1 |
| Paratyphoid B | 2 | menter, not identified ... | — |
| Streptococcus | 4 | | |
| Staphylococcus | 6 | Total | 121 |

—that is, the enterococcus was present in 16 per cent. of all blood cultures done. Blood culture is a very valuable method of diagnosis when positive results are obtained, but it is disappointing that in many cases of apparent septicaemia no organism is found. It has been observed, especially in cases of myalgia, that one is more likely to obtain positive results if blood cultures are made at the beginning of the pyrexial period. This observation is interesting, as in the enteric group of diseases the infecting bacillus is rarely obtained from the blood after the first week of illness.

(b) *Wounds.*—The method adopted to determine the presence of the enterococcus in wounds was as follows: The pus was plated out on agar and on Conradi-Drigalski's medium and tubes of broth and of milk were also inoculated. After 24 hours' incubation, growths, if any, were examined microscopically, and the presence or absence of the enterococcus determined. In cases of doubt as to the nature of growths resembling the enterococcus the pus was also examined by the pyo-sero method of Wright and by the heat test above described. The following table gives the results of the routine examination of wounds:—

| | |
|--|-----|
| Enterococcus alone present | 5 |
| Enterococcus with other micro-organisms | 41 |
| Enterococcus not found | 64 |
| Total | 110 |

—that is, the enterococcus was found to be present in 41 per cent. of infected wounds.

(c) *Urine.*—The method employed with urines was as follows. The orifice of the urethra was cleansed with antiseptic lotion and the patient asked to pass urine. Some of the middle of the stream was received direct in two sterile test tubes. Specimens thus collected were incubated at 37° C. for several hours, and then loopfuls of the deposit plated on agar and on Conradi-Drigalski's medium. The two common methods of collecting specimens of urine for bacteriological examination—namely, catheterisation and the method described above are open to criticism. In both

contaminations from the urethra may occur. In the first, if micro-organisms are present in the urethra it is practically impossible to avoid carrying them into the bladder on the catheter. In the second, urethral organisms may be washed out by the stream of urine. As all the patients whose urines were examined were males the method above described, being the simpler, was adopted. The following are the results of the examination of 543 urines:—

| | | | |
|-----------------------------|-----|--------------------------------|---|
| Sterile | 124 | Staphylococcus and B. coli ... | 3 |
| Staphylococcus | 184 | Staphylococcus and various ... | 8 |
| Enterococcus | 66 | Enterococcus and various ... | 1 |
| Streptococcus | 39 | Streptococcus and B. coli ... | 2 |
| B. coli | 13 | Streptococcus and various ... | 2 |
| Various | 24 | Enterococcus and B. coli ... | 3 |
| Staphylococcus and entero- | | Staphylococcus, B. coli, and | |
| coccus | 28 | enterococcus | 1 |
| Staphylococcus and strepto- | | Staphylococcus, B. coli, and | |
| coccus | 44 | streptococcus | 1 |

The enterococcus was present in 18 per cent.

The presence of micro-organisms in the urine is of varied significance. Staphylococci often occur, streptococci less frequently without any importance being attached to their presence. If, however, the tubercle bacillus, a bacillus of the enteric group, or the micrococcus melitensis be found there is presumptive evidence of a definite infection. Our experience with the enterococcus appears to show that when the organism is found in urine it is frequently an infecting agent. It may be, however, that its presence in urine is not always of pathogenic significance, and in absence of confirmatory evidence of infection undue weight should not be attached to the discovery of the coccus in the urine.

(d) *Sputum.*—When examining films of sputa an organism morphologically resembling the enterococcus was sometimes observed. It was also noticed that in certain cases treated with enterococcus vaccine a reaction of such a nature occurred as to suggest the possibility of the presence of this organism in the sputum. Having discovered by the heat test that the enterococcus sometimes occurs in sputum, this method of examination was applied to 23 sputa from cases of several different diseases, and the organism was found in 8. In these 8 cases there was other evidence of infection with the coccus.

2. *Result of opsonic index determinations.*—The determination of the opsonic index is the only laboratory method of general application for ascertaining whether a micro-organism isolated from the body is infecting the patient. In a number of the cases described opsonic determinations were made and evidence of infection with the enterococcus found.

3. *Vaccines in diagnosis.*—Until a month ago autogenous vaccines were used in practically every case where the organism was found. Latterly stock vaccines prepared from a number of strains have proved equally useful. The employment of vaccines as a method of diagnosis is to some extent comparable to the use of tuberculin for this purpose. Our practice was to give small doses—2½ millions or less—as many of the patients were found to be extremely sensitive. The vaccine being used therapeutically as well as diagnostically, the effect of a series of inoculations could be observed, and it was generally possible to form an opinion as to whether the vaccine employed was the correct one or not; in other words, whether the enterococcus was an infecting organism in the case under consideration. A febrile or general reaction following an inoculation, especially if associated with a focal reaction, is evidence that the organism from which the vaccine is made is at least one factor in the patient's illness. The more acutely ill the patient is the more sensitive is he to the correct vaccine. In febrile cases marked reactions are undesirable, but the course of the temperature in such cases is often extremely suggestive and may, in conjunction with other evidence, justify a definite conclusion.

As the course of the illness in many of the cases under consideration was prolonged and the duration of the patient's stay in this hospital seldom exceeded a few weeks, it was impossible to put the patients on a full course of vaccine therapy. The limited treatment, however, which they received appeared to be of decided benefit. When the immediate reaction following a dose of vaccine had passed off the pains were usually much relieved and the general condition of the patient improved.

THE DIAGNOSIS OF TUBERCULOSIS BY TUBERCULIN.

A STUDY IN TECHNIQUE.

By H. A. ELLIS, M.B., B.S. DUB.,

TUBERCULOSIS MEDICAL OFFICER, MIDDLESBROUGH; EX-SUPERINTENDENT,
COOLGARDIE SANATORIUM, WESTERN AUSTRALIA.

THE question of the early recognition of active tuberculosis is so important that any investigations which tend to make it easier or more definite should appeal equally to the general practitioner and to the specialist. It is generally recognised that the cure of most cases of active tuberculosis in its early stages is quite an easy matter given the necessary time and opportunity. Cure is understood to mean the general raising of the resistance of the system in relation to the tuberculous virus, so that the virus does not either endanger life or by its presence interfere with comfort or health. The early curability being admitted, the earliest possible recognition naturally becomes a question of paramount importance.

When this investigation into the early recognition of tubercle by means of tuberculin was commenced the postulates which were considered as proved were: First, that the action of tuberculin was specific in the case of tuberculous infection—in other words, a similar reaction could not be produced by any other agency than the tubercular virus itself or its products; secondly, that a reaction was considered to prove that the tubercle bacillus had been present in the organism at some time or another; and, thirdly, that the tubercular virus could be present without there being active disease.

Evidence has accumulated to a convincing amount that by far the greater portion of the population has at some time or another of their career been infected with the tuberculous virus, but in most cases it has not caused any injury, and its presence cannot be detected except with the aid of tuberculin. A minority of those infected suffered from what is called in this article active tuberculosis; the remainder, in all probability stimulated by the presence of the tubercular organism itself, have no doubt acquired a certain amount of immunity by which subsequent infections are satisfactorily controlled without any injury or without even any cognisance of its existence.

Accepting as a fact that the tubercular reaction is specific, there are five ways in which it can be obtained in order to arrive at a diagnosis. They are: (1) Koch's method, subcutaneously applied to the organism generally; (2) von Pirquet's, applied to the mucous layer of the skin; (3) Moro's ointment, superficially; (4) Calmette's, to the mucous membrane of the eye; and (5) Martoux's intradermal reaction. One and all yield positive results where the organism had been in contact with the virus. They have not obtained general acceptance because they are too sensitive—have proved too much—producing definite reactions in many cases that were evidently not suffering at all from active disease. That was the position when these investigations were begun some four years ago, and I have not yet seen whether multi-Pirquet, subsequently introduced, has been standardised or not.

It appeared to me at the time absurd for our modern spirit of investigation to abandon a definite method of acquiring information in so important a disease simply because the test was too sensitive, for that was really the position when the objections to the tests were brought down to bedrock. The main reason that tuberculin is not universally used as the test for tuberculosis is that too many respond. It is true the subcutaneous method was not used by some because it was considered too dangerous. I, in the main, agree with this conclusion. A simple von Pirquet is too delicate; in fact, it is useless for anything but a negative test. From what I have seen of Koch's subcutaneous method in the hands of persons inexperienced in the use of tuberculin it would be dangerous if indiscriminately applied. Of Calmette's and Moro's I have too little experience to speak authoritatively, save to say that I was unwilling to use Calmette's in my earlier investigations on account of the definite precautions necessary in its use. The attitude then taken has been confirmed in the light of subsequent knowledge. The result of a series of investigations which I hope

to record at a later period leads me to the belief that the application of the eye test in general practice by those unacquainted with tuberculin is questionable.

This being the position as far as I was aware of it when these investigations were first started, the first thing that appeared necessary to settle was whether tuberculin reaction was confined to any one tissue or whether its effect was equally general to all tissues. It was definitely recognised that the reaction was threefold: (1) local, at the seat of the application; (2) focal, at the seat of the disease; and (3) general, in the constitutional disturbance resulting; but I was uncertain what definite tissues reacted except those tubercularly infected.

The first reaction investigated was naturally the local, and the investigations were carried out in the Coolgardie Sanatorium in Western Australia, an institution with 90 beds, where I had to treat all varieties of cases sent in by the Government without personal selection.

In investigating the skin reaction the first layer tested was the mucous layer, the one on which von Pirquet operated, as he specifically mentions that blood should not be drawn. Von Pirquet says: "The scarifier used is a chisel-shaped point of platinum-iridium about one-sixteenth of an inch in width. It is held vertical to the skin and rotated. The amount of abrasion should be such that the control spot shows a scab the next day, *but blood should not be drawn.*" To separate this layer from the other with a view to investigation of the results blister plaster was used. It required a little care to produce a blister of the right size and consistency, so that the secreted fluid could be withdrawn and various quantities of tuberculin substituted without breaking the covering. The various dilutions were not at this time being accurately investigated, but the question whether the mucous layer was the layer responding or not was very soon settled.

The procedure ultimately adopted was to raise a blister with a plaster about the size of a threepenny-piece, the plaster being applied eight hours before the injection was made, then by means of a fine needle inserted through the uninjured skin the fluid of the blister could be easily withdrawn and the tuberculin dilution substituted for it. This carefully done could be accomplished without bursting the blister. The puncture point was then sealed with collodion and the results noted. No local reaction was obtained by this means at all, although both focal and general reactions were obtained. In fact, this method was used later as a means of conveying tuberculin into the organism. It was found in many cases that tuberculin could be used in this manner beneficially where the organism was otherwise too sensitive to injection. The valuable feature of the process is the slow rate of absorption, as it takes two to three days for the blister to be absorbed. During both the original investigations and later experiments when using the blister for inoculation purpose I do not think any definite local reaction was ever obtained. It must be remembered that in these cases very concentrated tuberculins were not obtained because there was a certain amount of dilution with the blister fluid remaining.

The next layer to be investigated was the papillary layer of the skin in which the smaller blood-vessels run, and it was very soon manifest that the papillary layer, at any rate whatever other layers were involved, was keenly sensitive to the tuberculin reaction. I have never satisfactorily demonstrated whether this is due to the cutaneous elements of that layer or whether it is due to the connective tissue, as there was no means of section-cutting, and if there had been the necessary skill would have been in question. However, the general impression obtained was that the epithelial element was the one involved. This opinion was arrived at mainly by the needle-point reaction, which, it is admitted, is the most sensitive tuberculin reaction which exists, and also by a series of investigations in which the skin was penetrated from below, the needle being first driven through the skin and then carried up again to the lower epidermic layers after passing through the subcutaneous tissues. That there is some reaction in the deeper layer is undoubted, because there is frequently a general swelling produced even by comparatively small doses. But this appears to be by no means as sensitive as the superficial or papillary layer. Further evidence that the epithelial element is the one

¹ Handbuch der Technik und Methodik der Immunitätsforschung, von Kraus und Levaditi, p. 1035 (1908).

involved could be produced from certain lupus reactions, but that belongs to their special investigation and would take too long to detail here. Incidentally, the fact that the specific reaction takes place in the deeper epithelial layer explains to a large extent the erratic results obtained by von Pirquet's superficial cutaneous method, as when the papillary layer was accidentally injured much more definite results would be obtained than when it was uninjured.

These observations led to the adoption of the method detailed in this paper called the papillary cutaneous method (or shortly P.C.) and multi-papillary cutaneous (or M.P.C.) when various dilutions are used. This is done to distinguish it from von Pirquet's or the mucous cutaneous method. It soon became evident that the original solution (O.T.) produced results far too numerous to yield any reliable conclusions, as it undoubtedly gave a reaction in many cases where no sign of active disease existed.

Tubercular cases have to be divided into two classes, active and passive, with the intermediate stages travelling in each direction, active passive and passive active, signifying that the case is either passing from an active state to a passive and not definitely either or from passive to active. When cases are passing into an active condition the battle is naturally going in favour of the virus.

The observations recorded here are the outcome of the study of over 700 cases to which the method has been applied. The cases actually recorded are the last 500 which have been dealt with since my appointment as tuberculosis medical officer at Middlesbrough. These have been done in rotation as they present themselves, and they are all recorded.

As every case has to come to me through another practitioner, there must naturally have been some presumption in favour of tuberculosis before they came into my hands. The children recorded were mostly sent by the school medical officer (Dr. H. M. Gay), who sends in every doubtful case for investigation. He has examined so far some 8000 cases. Three-fifths of the cases here recorded are children, and in their case the probability of tuberculosis was not so great on account of their routine method of selection. This is amply borne out by the figures, as the children gave 74 absolute negatives in the 333, whereas the adults only gave 6 in 167.

P.T.O. is used for the first mark "I" or original solution mark. O.T. is used for all the others. The dilutions of T. used are 1 in 10, 1 in 100, 1 in 500, 1 in 1000, and 1 in 10,000. The diluent used is that in general use—normal saline and $\frac{1}{2}$ per cent. carbolic acid. For the purpose of record they are labelled in the following way:—

| | | | | | | |
|------|-----|-----|-----------------|-----|-----|-----------------------|
| I. | ... | ... | Original P.T.O. | ... | ... | Earlier cases were T. |
| II. | ... | ... | 1 in 10 | ... | ... | Old tuberculin T. |
| III. | ... | ... | 1 in 100 | ... | ... | " " |
| IV. | ... | ... | 1 in 500 | ... | ... | " " |
| V. | ... | ... | 1 in 1000 | ... | ... | " " |
| VI. | ... | ... | 1 in 10,000 | ... | ... | " " |

Diluent: Normal saline and $\frac{1}{2}$ per cent carbolic acid.

The cost of a bottle of 1 c.c. of T. or P.T.O. is about 6d., sufficient for six cases when done individually. All the dilutions can be made with a good tuberculin syringe graduated in tenths, a bottle of old tuberculin, and a bottle of diluting fluid. If it is desired to do a "I." a bottle of P.T.O. as well is necessary. Supposing T. is used all through, a little more than a tenth of a c.c. is taken into the syringe first and a small drop is placed on the forearm sufficient to bring the syringe up to the tenth mark. That makes the original or "I." which is then scarified. The syringe is then filled with the diluting fluid to the top, leaving, however, a bubble to ensure it mixing. The needle is then wiped with cotton-wool, and the bubble moved up and down and a few drops discarded, then another drop placed on the arm just below the previous one, and then scarified, which makes "II." or the 1 in 10 mark. The syringe is then emptied to the tenth mark and a further fill of diluting fluid made with the bubble as before. This procedure makes the "III." mark or 1 in 100. For the "IV." mark the syringe is emptied to its tenth mark, and is then refilled, but this time only half way, making the "IV." or 1 in 500 dilution, and after the scarification it is filled completely with diluent without emptying anything out, making the "V." or 1 in 1000. In the last or the "VI." dilution it is emptied to the tenth mark, and filled up as in the earlier marks. The diluting solution is then used for the control. The needle must be wiped every time, and after mixing a few

drops forced out to ensure no contamination or dilution. The needle often contains as much as 1/100 c.c., which can be easily verified by emptying the syringe, then drawing back the piston, and seeing how much fluid remains in the syringe. When P.T.O. is obtainable it is better to do the original with it, or if the case is suspected of being sensitive "I." should be omitted altogether, remembering to record the first mark as "II."

For use on a large scale six little bottles are requisite with a drop-stopper drawn to a fine point, so that a small amount can be easily deposited on the left forearm, the place invariably used as most convenient. The skin in the higher part is insensitive and at the same time fairly thin, the sensitiveness increasing as the wrist is approached. If the marks are properly placed they occupy a line under 2½ inches in length, which should be in the upper two-thirds of the forearm.

The original solution which was used at the commencement of these experiments for mark "I." was T.—Koch's original tuberculin—but as it gave such high reactions it was ultimately discarded for P.T.O., as that was found to be safer. Since P.T.O. was used at the original "I." mark there have been no excessive local reactions. It is true that this somewhat interferes with the sequence, as T. is used for all the other dilutions, but the safety more than compensates. In fact, my present advice is to drop T. for the original altogether as unnecessary except when an absolute negative is required.

The method of procedure is as follows. At each mark a drop of the dilution required is placed on the forearm, commencing at the elbow—1 minim is all that is necessary. Then, using a vaccinating lancet, with a round, very sharp point, a few quick movements are made through the drop and the superficial layer of the epidermis, about one-quarter of an inch long. The blood does not often appear until after the scarification at that mark has been finished. The lancet is wiped, and the same proceedings carried out with another dilution at a lower spot. The six dilutions are generally used, and the control, making seven in all. The essential points are that the bleeding layer must be penetrated, the scratch must be made through the solution, and the knife must be wiped so as not to carry any solution over to the next dilution and so vitiate the results. The lancet must be properly sharp, and there must be at least five small scratches alongside each other at each mark or the result is unreliable.

The whole is then covered with a small strip of absorbent wool over which a piece of gauze is placed, and the pad is retained in position for two days by a couple of narrow strips of zinc adhesive plaster round the arm. It causes no inconvenience or discomfort to the patient, though the procedure sounds rather dreadful; babies of 1 year of age do not even cry while it is being done. The whole process takes under two minutes, and there is no discomfort afterwards; in fact, they hardly know that anything has occurred. It is wise to tell the patients that the procedure is performed for the doctor's information, not to cause any reactions in them.

Sir William Osler has said somewhere that if tubercle throughout its active stages caused pimples to appear on the nose the disease would be more easily controlled, as it would be recognised quite early and attended to by the sufferers. This procedure might easily be considered to be the pimples.

Most medical men will find the moment for taking off the bandages at the end of the second day one of great interest, as the condition of the patient is then displayed before those who know how to read the results. When the bandage is removed the reaction will be found to display the following features. If the reaction is acute the marks will be red and swollen in a series diminishing with the strength of the solution and the activity of the case. The next characteristic will be the disappearance of the cut marks in contrast with the control; the swelling may be quite considerable, and is best appreciated by running the finger down the line of marks when it will be possible readily to recognise the mark at which the swelling disappears. Running the top of the thumb across each alternate mark is also a good way.

The colour varies in two directions from what is considered as normal reaction—about the colour of the lips. The brighter it is the more active and recent is the tubercular attack. When the swelling is considerable the colour is driven out of the mark itself, and it assumes a lighter,

oedematous appearance, suggesting a tendency to blister, and the bright colour reaction invades the neighbouring skin, sometimes to quite a considerable distance. When the swelling is slight or absent the colour of a reaction is much darker and is often delayed in appearance, in which case it is advisable to see the case again in three days and seven days before arriving at a definite conclusion. A darker reaction usually means an old infection. It may be so dark as to be nearly black, and that means that the case is old, quiescent, or one going to the bad with little or no resistance. The general condition of the patient will easily decide which of the two readings is to be recorded. In these cases there is little or no swelling. These colour reactions are being at present investigated and will be reported on later.

When investigating a reaction the points to be noted are: (1) The number of reactions, being the number in which the cut marks have disappeared; (2) the amount of swelling at each mark and the mark number at which the swelling disappears; (3) the character of the colour of the reacting marks; (4) the date of the colour appearance and disappearance; and (5) the mark number at which the colour disappears.

Another point which it is necessary to remember when reading the results of the test is that all considerations have to be taken into account and the balance weighed up. M.P.C. is reliable; but even then, the general condition of the patient must be considered in relation to the result obtained by the M.P.C. to arrive at anything like accurate conclusions.

In reviewing my early cases, the first thing that impressed me was the very large number that responded to the very high dilution of 1 in 1000 and 1 in 10,000—"V." and "VI." in the scale—and from my present knowledge I should expect reactions would occasionally be obtained from 1 in 100,000 and 1 in 1,000,000 if those dilutions were used, "VII." and "VIII."

The next general observation is that the number of marks in the cutaneous reaction does not correspond with the amount of tissue infected by tubercle, and neither does the cutaneous reaction correspond with the effect of tuberculin in focal or general reactions, but the M.P.C. results vary with a quite different set of conditions, which I call the curve of the M.P.C. reaction. The number of marks responding varies with two factors, the amount of tissue involved and the duration of the disease. It is more acute according as the activity of the disease is more recent. In regard to the amount of tissue infected by tubercle in relation to the number of marks reacting: the number of marks reacting increases very rapidly at first in proportion to the amount of tissue, but soon, however, reaches a maximum, and this with a very moderate amount of tissue infection; then with a further increase of the amount of tubercular infection the number of marks and amount of reaction to M.P.C. continue to diminish until no local reaction at all occurs when a large amount of lung is infected. Incipient cases involving only one lung focus give a "I." or "II." reading. Probably the amount of lung yielding a "VI." reaction would be a very small fresh patch, just definitely detectable by the stethoscope at one or both apices, and covering at most an area of 2 inches, larger areas and older disease giving fewer reactions. The usual moderate area gives "III." or "IV." on the descending scale, having passed their most sensitive condition; a large area gives "I." and "II." and very advanced cases give no reaction at all.

This creates the interesting position that any reaction may be on the ascending or descending line of the curve and may be due to an active-passive or a passive-active change, and consequently the question on which side of the curve the mark is has a very definite signification. By comparing photographs at the commencement and end of a course of tuberculin it was shown that the reactions were much diminished by the injections, a case yielding a "VI." reaction at the commencement of a course of tuberculin at the end would be "III." or even "II." and the acuteness of the swelling and colour of reaction were similarly reduced. This is, of course, in line with previous observations.

It might again be emphasised that the reading of the reaction has to be taken in conjunction with the other symptoms. M.P.C. can never constitute the whole diagnosis, but it easily yields half the available information; the other half still remains as essential as it ever was.

In the 500 cases here reviewed and classified many details are necessarily omitted for the sake of clearness. A more detailed classification is being arranged for the next 500, which I hope to complete during the present year. The present record only deals with the number of marks reacting, and not with the varied character of those reactions. The tables here presented were only compiled on the completion of the 500 cases and were arranged in hundreds to prevent any bias, and it is quite remarkable how each hundred repeated the characteristics of the other and bore out the general observations previously made.

Negatives.—Coming now to the consideration of the results as displayed in the tables themselves, absolute negatives and only indefinite reaction from "original," which is practically a negative, numbered 90 out of the 500, or 18 per cent. These are principally children sent for investigation on account of glands, some suspicious lung condition, or general appearances. The negatives recorded in children thus naturally far outnumbered the adults, because they were sent in routine from the school medical examination if there was any suspicion of tuberculosis. The adults were sent by general practitioners after mature consideration. Rarely where a negative occurred did subsequent observation make me suspect tuberculosis, and those few cases were among the earlier tests, before late examination of negatives for delayed reaction became routine procedure. These cases in no way vitiated the conclusion that a negative or slight reaction is valuable evidence in excluding active tubercular disease in cases where otherwise it would be considered the most probable cause. If patients are told that the M.P.C. test is made to disprove the existence of tuberculosis and not to prove that it is present, it frequently sets their minds at rest, and they allow the test willingly.

Negatives have been found especially useful where there is a doubt between septic and tubercular glands, although the condition sometimes co-exists. In many of these cases, chiefly children, we were able definitely to exclude tuberculosis and state that the glands were septic, and tell the patients that they should have either their noses, tonsils, or teeth attended to in order to remove the cause, generally with satisfactory results. Where bronchitis or asthma was present it has been possible to exclude tuberculosis as the main cause. Likewise in a specific knee-joint and in a case subsequently shown by X ray to be suffering from cervical ribs, thought to be spinal tubercular disease, M.P.C. excluded tuberculosis.

Other examples might be given of unexpected and valuable negatives recorded. M.P.C. is particularly valuable in the examination of tubercular-looking children suffering from various forms of other diseases. Tuberculin is the only satisfactory way in which the tubercular virus can be excluded—a matter of extreme importance to the patient. One must be careful not to include a delayed colour reaction as entirely negative. Delayed reactions have some value in suggesting further investigations in a doubtful case, but these are relatively so rare that the general propositions hold as stated.

The non-responding tubercular classes who either do not react at all or only very slightly to M.P.C. are the meningeal, intestinal with dilated abdomen, pleuritic, and the dying. It will be noticed that all these classes presuppose that a considerable quantity of tuberculin is secreted in an easily absorbable form, which would naturally prevent reaction appearing. This constitutes a special condition which may be called tuberculin reaction paralysis, and would naturally suggest an earlier stage of anaesthesia existing previously in which the power of the reaction to tuberculin is diminished, not obliterated. This condition would be the natural antithesis of the hypersensitive condition. Such conditions are interesting and important, but the discussion of them at present would lead me too far from the subject of this paper, which is really one of record.

It remains, however, to say that cutaneous sensitiveness must not in these cases be mixed up with either the general or the focal reactions, as they act in different and, in some cases, opposite lines.

Marks "I." and "II."—Next to the negatives come those cases reacting to the stronger tuberculin, a reaction demonstrated both in colour and elevation—namely, responses to original T. or P.T.O. and to a dilution of 1 in 10 of T., being classified as "I." and "II." There are 102 such cases, or 20 per cent. of those tested, of which 43 were

adults (8 per cent. of the whole) and 59 were children (12 per cent.). The adults reacting to "I." and "II." can be divided into two classes, advanced or dying cases and very slight cases. There were 20 advanced cases in this group (9 are already dead) and the rest are dying. The remaining 21 are only slightly infected (1 and 2 of Astor classification), and will probably easily re-establish their resistance, which in some cases is practically unimpaired, as shown by slight reaction given.

Thus, we see in adults when the response to the M.P.C. test is slight it divides cases into two easily distinguishable classes: (1) those very far advanced, and (2) those with slight infection. There are no intermediate cases. This group will be seen to differ from later groups in this respect. A slight response suggests either that a small amount of tubercular infection has taken place or that so much tissue has become involved, with the consequent extensive absorption of products causing tuberculin paralysis, that the resistance of the individual to the disease is practically at an end. It must be remembered that the same absence of reaction occurs after a course of tuberculin, which itself produces a condition of tuberculin anaesthesia—a matter of great importance to the patient.

Both ends of an infection, therefore, give the same number of reactions, the advanced case giving a dark reaction with slight elevation and often a delayed appearance, whilst the incipient case is brighter in colour and more elevated. Real brightness of colour is, however, rare in the mild case, more generally the colour being what I record as normal—about the colour of the inside of the lips—and the elevation being slight but distinct, suggesting that the balance of tuberculin resistance is well in favour of the patient. The two exceptions in the table to the advanced reaction pointing to a dying condition are interesting in that they are two advanced cases that have been put on a new treatment and are at a standstill. This is only mentioned incidentally to complete the record.

As regards slight reactions among the children, there were 59 who responded to "I." and "II." or 23.6 per cent. of the children tested. The same division into slight and advanced cases occurs among the children as among the adults. There were 39 slight lung cases, or 66 per cent. of the group, and 10 advanced cases, or 16 per cent. of the group. With children advanced lung lesions do not seem to be so fatal, and there is a larger amount of bronchitis intermixed with them. There is also a much greater difficulty in differentiating between the temporary and the permanent lesions except by extended observation—taking time. The other cases in this class beside pulmonary were various slight affections of the eyes, bones, &c., and cases that have had tuberculin treatment given before testing, which, as we have seen, lowers the reaction and must always be remembered when interpreting the results.

The absence of tubercular glands from this class is most noticeable. Tubercular glands give normally a higher reaction, making the differentiation between them and septic glands much easier. It has been a matter of doubt as to how far the two reinforce each other. They seem undoubtedly to do so in many cases, while, on the other hand, there are many large glands in which no septic character is traceable. Whenever affected glands exist the reaction tends to be higher, but this will be considered when recording double infection which occurs amongst the later reactions.

Mark "III. (?)"—Coming to the next group, Class "III. (?)"—a special class—it is here that the difficulty begins, and its correct reading will certainly puzzle when one commences to apply the test. M.P.C. marks are usually recorded as positive or negative, but frequently they are indeterminate. By indeterminate is meant that the elevation and colour differ only very slightly from the elevation and colour of the control, and it would, therefore, be a question if the mark stood by itself as to whether there was any reaction or not, but there is still a difference, which is quite distinct if careful observation is made when it occurs after a series of definite reactions. In some cases the line between positive and negative is so marked that there is no question about the result, but in the majority of cases there are one or two doubtful marks between the definite negative and the definite positive, which are recorded as questions (?). These doubtful marks never occur until the definitely positives are finished. They do not occur indiscriminately. The only

place in the series where they are of real importance is at the hundred dilution mark ("III.").

If "III." is positive it is in favour of the active disease. The statement is not made dogmatically, because I always throw the responsibility on the other side and leave it for others to say that active disease is not present when there is a response to 1 in 100 dilution. When that reaction is recorded I believe the onus of proof is to show that the tubercular virus is not active. To adopt the negative course, though rather comforting to the patient, would in most instances be highly dangerous. Certainly I hold that if a case responds to a "III." dilution positively I have to satisfy myself that the disease is not active, but if only "II." is positive and "III." is definitely negative I allow the general condition of the patient to influence the decision if the symptoms are slight. Hence the importance of the "III." (?) as a class.

The greater number of cases recorded in the table (13 out of 20) are still slight, but intermediate cases begin to appear. The more serious cases also diminish proportionately, and their condition is not so serious. There are no dying cases in this group at all and the slightest cases are more active as a class.

In following out the classification of tuberculosis, according to the Astor report, into six classes, as I have in my records, there is one distinct disadvantage. In Astor's classification 3 is kept for acute cases only. As acute cases occur all through the series of classification I consider that adding "A" to the Astor number would give far preferable results and would prevent crowding all the intermediate and bad, but possibly curable, cases under heading 4, as I have found so disadvantageous in making this classification. "Advanced," practically takes in not only the dying and bedridden cases, but also those with extensive mischief which has become quiescent. A patient can often go about, and in some cases even return to work, when, if lung conditions were only considered, he should apparently be classed in Astor's fifth class. These cases would be better classed as 4 and the milder cases with larger area should be classed as 3. In active cases "A" should be added to the class, thus there would be 4 A as well as 3 A.

The difficulty in the existing Astor classification is that extensive lung mischief and advanced cases are not synonymous conditions. In these records there is some ambiguity produced by this difficulty in classification. So for the purpose of this return it has been deemed advisable to divide tubercle into the old classes of slight, intermediate, and advanced. "Slight" comprises 1 and 2 Astor classification; "intermediate" being practically 4 of Astor classification as the acute cases (3) are naturally rarely seen, as they are usually confined to bed. "Advanced" would be practically 5 of Astor classification, as 6 would not often be seen at the dispensary for the same reason as 3.

In considering the children reacting to "III." (?), they are all practically composed of slight lung and slight gland cases, which latter begin here to first appear. In their case this group does not take such an important position as in the adults.

Marks "III." and "IV."—Now we come to the group comprised by "III." positive and "IV." mark M.P.C., or where the reaction is to dilutions of 1 in 100 and 1 in 500. This group comprises the main number of active treatable cases and makes far the most numerous group, being 39 per cent. of the whole number. It totals 73 adults, or 45 per cent. of those responding. It will be noticed in this group how much more evenly the various stages of the tubercular disease are distributed than is the case in the previous groups. Patients in the intermediate stage of the disease number 25 (or 34 per cent. of the group), nearly equalling the early cases—30 (or 41 per cent.). The advanced are only 6 and have fallen proportionately from 49 per cent. of the first group to under 8 per cent. of this class, and they are not by any means so far advanced.

With children instead of lungs glands have now become the predominant trouble, and the 40 slight cases (34 per cent. of the group) and the 38 intermediate (31 per cent.) occupy nearly the whole class, the intermediate and advanced cases being practically all gland cases, which type are much more liable to reaction to tuberculin. This was further emphasised by their subsequent sensitiveness to inoculation.

It is interesting to note in connexion with this class responding to "III." and "IV." dilutions that here the

double infection first appears. By double infection is meant the infection of two dissimilar tissues. It has been noticed that double infection gives a higher reaction than would be expected from the same amount when only single tissue is involved. This is most marked where the complication is glands, then the anæsthetic tubercular condition does not occur so easily.

Marks "V." and "VI."—Now coming to the last group, those reacting to "V." and "VI." M.P.C. the point of greatest interest is the number of cases that reacted to such a high dilution of tuberculin; 72, or 14.4 per cent., of the whole number tried are in this class, the adults giving 25 cases, or 15.5 per cent., and the children giving 47 cases, or 19 per cent. It is also noticeable that double infections here predominate, amounting to more than half. Of the total of 72 reacting 40 show double infection, the adults being 56 per cent. of their class and the children numbering 26, or 5.5 per cent.

When there is slight or even moderate double infection the hypersensitiveness may be acute and tuberculin injections must be used with great care. This is emphasised by double infections not appearing till dilutions "III." and "IV." are recorded. The 3 cases in which the skin ulceration occurred when old tuberculin was used for making the original mark in days gone by were all strong, stout girls belonging to the double infections class, whose response was of the highest, and even the "VI." mark showed such a strong reaction that they would probably have reacted to "VIII." or 1 in 1,000,000 if it had been tried, and their subsequent history, though they are all doing well, showed how a dormant focus was very liable to light up. In spite of the fact that they kept the upper hand of the virus, their margin of safety was not very great, the tubercular anæsthetic condition being particularly difficult to produce. The ulcers were clean cut and superficial, not going to any depth, and they rapidly healed. The dermatitis which occurred was not in any way complicated by any skin disease or by the tubercular bacillus itself. These considerations, however, have really more relation with the lupus investigations, which it is proposed to record later.

Sixteen of the children had advanced glands, showing large lumps on the side of the neck; "advanced glands" being recorded when the glands are prominently noticeable on first seeing the patient. "Intermediate" is recorded when they are immediately apparent to touch.

It may be observed in passing, although not properly belonging to this article, that tuberculin should be injected with great caution when there are large glands and the dose should be very slowly raised. These investigations may explain the reason why so much difference of opinion prevails about the use of tuberculin. Here also will probably be found the key of many different results and records, and certainly after one is intimately acquainted with the reaction of the M.P.C. there would be considerable hesitation as to the quantity of the dose to begin with and the rapidity with which it is advisable to increase the dose without its guiding information. It may also be as well to put on record, although it will be dealt with more fully in a subsequent paper when more complete analysis of the reactions come to be tabulated, that the P.T.O. used for mark "I" has given a definite indication as to whether there is a bovine infection or not, as absolute negatives to original P.T.O. are not uncommon when T. responds in as high a dilution as "IV." or 1 in 1000, but the contrary condition is very rare.

Returning to Group "V." and "VI.," although cases in this group are hypersensitive, and on account of that sensitiveness must be considered dangerously balanced cases, the records of the past year go far to show that under careful treatment they do very well. The details of their treatment would lead me too far from my present purpose, but it is well to put on record that very high reactions do not in themselves mean that any dangerous result may be anticipated, but rather the reverse. Results are good, but high reactions do emphasise that more caution must characterise the treatment. These cases are much more liable to sudden and sharp extensions of their lesions, and so require constant watchfulness. The advanced cases recorded are all acute gland cases in this group, and have all done well. It might be stated that the tubercular focus produces a purely inflammatory infection much further into the surrounding tissue in these cases rather than a definitely

infectious invasion, in contradistinction to the other end of the M.P.C. sequence illustrated in "I." and "II." when infiltration of the tissue by the virus and its products seems to occur with little or no inflammatory resistance.

The further details of the meaning of each individual class would make this preliminary report too complicated. Here it is only desired to deal with general results.

In reporting to doctors on their cases forwarded for opinion no dogmatic attitude is taken up, but reports are worded that the case responds to 1 in 100 ("III.") M.P.C., and so on, with such evidence of lesion as exists. The suggestion is made where the lesion is slight and the response is above 1 in 100 ("III.") (?) that the condition is probably active and will be benefited by treatment. If mark reactions are more extended it is wise to give patients the benefit of the doubt and treat them for active disease. The number that do not benefit as the result of such treatment will be found to be quite negligible. When this view is not taken and the danger is neglected quite a number, as their subsequent career shows, have taken the wrong turning.

One result which appears sufficiently definite, but which will require much deeper and extended observation, is the relation of the curve of tuberculin in the M.P.C. to the amount of tissue and the kind of tissue involved, and also its relation to the time of the occurrence of the active infection. It has only been demonstrated here that such a curve exists, and that it is definite and characteristic. Much more extended and wider observation will be necessary before its variations are accurately known. Suffice it to say that cutaneous reaction commences with a slight amount of infection, very rapidly reaches a maximum, and then gradually subsides. The controlling factors of the height of the curve, other than double infection, have not been elucidated, except that increased height of mark means increased activity and darkening of colour greater passivity or age of reaction, the danger of the case being proportional to the dark colour and low infiltration if the case is going to the bad. The slighter elevation and fewer dilutions reacting are favourable to the case if it is on the improving side.

Dealing with some side issues I may mention that a very valuable means has been given of estimating the strength of dilution of various tuberculins and the relative reactions of various kinds of tuberculin. There has not been time to make more than a few tentative experiments, but they go to show that the higher dilutions do not keep more than a fortnight, and that the reaction of fading dilution is somewhat of the same nature as an old tuberculous infection.

In conclusion, to sum up these observations and results here believed to be demonstrated.

First, that the papillary layer of the skin is the one most influenced by tuberculin, and that that layer reacts to graduated doses, in definite proportions to the dose employed, with mathematical accuracy consistent with the character of the case—that is to say, "III." mark never reacts more than "II." and the result being definitely proportional to the dose and the final reaction.

Secondly, the results appear definitely to indicate that when the M.P.C. reacts above "II." or 1 in 10, especially if colour reaction occurs, the onus of proof that the case is not suffering from active tuberculosis lies with the opposition.

Thirdly, the results also show that there is a distinct connexion between the M.P.C. reaction and the class in which the case is, and this relation is sufficiently definite to be a great aid to diagnosis and prognosis. When they do not apparently agree further investigations can generally demonstrate the cause; for instance, the lowering of the reaction caused by a previous course of tuberculin treatment.

Finally, the results also indicate that the highest M.P.C. reaction occurs comparatively early in the case; a greater subsequent extension of the disease gives a lower reaction.

It is hoped that sufficient evidence has been brought forward to justify the statement that M.P.C. properly and accurately carried out materially facilitates the early recognition of the condition of active tuberculosis, and is a material aid towards a general prognosis and a valuable indication in tuberculin treatment. If these matters have been put into a class of theories that should be proved or disproved the purpose of this paper has been accomplished.

Middlesbrough.

A NOTE ON THE USE OF CELLULOID IN PLASTIC SURGERY.

By CHARLES HIGGENS, F.R.C.S. ENG.,

OPHTHALMIC SURGEON TO GUY'S HOSPITAL AND TO THE COUNTY OF LONDON WAR HOSPITAL.

DURING the past six months I have had the opportunity of doing some 80 to 100 plastic operations on the face. The greater part of them were for scarred and lacerated eyelids and shrunken sockets, but I had quite a number of deeply scarred faces, and noses smashed as flat as I can imagine trenches are after a bombardment. At the beginning, with the exception of what I had learned in many years of ophthalmic practice, I knew about as much of this branch of surgery as the historic cow knew of the proverbial musket, but I soon began to recognise the want of a material which would make up deficiency of bone, fill up cavities, and level up hideous depressed cicatrices.

Quite early I began to look about for such a material and some method by which scars could be more or less obliterated. I tried paraffin, but without much success. When used to fill up a scar it would generally find a way to wriggle out of the position it was placed in and was anything but satisfactory. The removal of cicatrices and bringing the skin together over their former position was not more successful, for the new wound generally managed to accommodate itself to the previous conditions, and the deformity was but little improved.

Then it occurred to me to try celluloid. It seemed to me that it was a harmless substance and not likely to set up irritation; in this subsequent experience has not disappointed me. I have used plates of celluloid for replacing bone, and solutions for filling cavities and raising deep cicatrices. I have two solutions—one celluloid dissolved in acetone, the other a secret preparation made originally for trade purposes, its use being to make bad corks water-tight and air-tight. It appeared to have a great future from a commercial point of view, but the war came and spoilt its chance. This I think the better of the two.

At first I placed quite a number of plates of celluloid beneath deep cicatrices with most excellent results; the scars have become flat, are wearing out as time goes on, and not the smallest amount of irritation from the foreign body has occurred. I have also used it for replacing bone, and have built up three quite respectable noses with celluloid bridges. I have in all cases covered the celluloid over with skin taken from the remains of the part to be reconstructed or by flap removed from the immediate vicinity and left attached by a pedicle. The only precaution I have found necessary to adopt is to take care that the edge of the celluloid plate, which is rather sharp, should not coincide with the line of suture after the wound is closed; otherwise it may push its way out before healing has taken place. This is easily obviated by under-cutting the outer edges of the wound to be filled, and pushing the edges of the plate beneath the skin so raised that its margin is external to the line of suture.

Lately I have given up using plates for cicatrices in favour of the fluid preparation. The method I adopt is to make a small incision in the normal skin just beyond one end of the scar, then with a Graefe cataract knife in the case of small short scars, and with a scalpel or chisel such as is used for mastoid operations in the longer ones, separate it from the parts beneath. When this has been freely done I inject the fluid, or rather semi-fluid, celluloid into the tunnel so made until the scar rises a little above the surrounding surface. I then remove the syringe and smooth the scar down nearly level, finishing by closing the wound with a collodion dressing. The piston of the syringe used should be worked by a screw, because the solution is too thick to pass readily through the nozzle, and so much force is required that steadiness and equality of flow are difficult to ensure if the piston is forced in by hand pressure only. I am more than satisfied with the result of my celluloid operations, if I may call them such, and think there is a great future for them. I have had some celluloid fracture-plates made, but as yet have not had the opportunity of using one. I think it is quite probable that they may take the place of the steel plates at present in use.

Since I wrote the foregoing my colleague, Major Pailing, has filled an opening in the skull with a celluloid plate. The edges of the plate, which was curved to correspond with the curve of the skull, were pushed between the bone and dura and covered by the scalp. The operation was performed on Sept. 15th. On the 26th there had been no bad symptoms of any kind, pulse and temperature being normal during the whole time, the wound was firmly healed, and the patient said the only thing he noticed was that he had entirely got rid of headache which had troubled him for some weeks.

Brook-street, W.

A CASE OF CHORION - EPITHELIOMA.

By H. NEVILLE TAYLOR, M.A. CANTAB., M.A.,
M.D. DUB., F.R.C.S. EDIN.,

SURGEON, EBBW VALE HOSPITAL; CONSULTING MEDICAL OFFICER,
EBBW VALE APPROVED MEDICAL SOCIETY.

It is said that there is ground for believing that chorion-epithelioma may in exceptional instances remain latent for a considerable period; some few cases of such a delayed incidence of as long as two years after the pregnancy to which the disease was attributed have been recorded. The following case somewhat supports the view of the possibility of such a latent period.

FIG. 1.

Showing branching masses of syncytium; masses of differentiated cells; blood spaces. $\times 250$.

A woman aged 38, the mother of three healthy children, the youngest two years old, began to suffer from some irregular uterine hæmorrhage which gradually became more abundant; there had been no amenorrhœa since her last pregnancy. She was curetted in a provincial hospital and was discharged, temporarily at least, improved.

About a month afterwards I saw the patient in consultation with her medical attendant; she was then suffering from metrorrhagia and vomiting. On examination the uterus felt somewhat enlarged and soft, and there was a little blood oozing from the cervix. It was thought that, though there had been no preliminary amenorrhœa, the probability was that she had had an early abortion and that there might still be something retained, and a fresh curetting was discussed, but the vomiting and hæmorrhage subsided in a great measure under medical treatment. After about three weeks or so I was asked to see her again as the bleeding had

recurred more or less suddenly and more copiously than ever. She was very anæmic and had altogether changed for the worse, with a very "malignant" look about her. I admitted her to hospital, and that afternoon under chloroform removed with a blunt curette some unmistakably malignant fragments. She was very collapsed from the effect of the anæsthetic and the further bleeding, and she died somewhat suddenly from syncope in the early hours of the next morning.

Whether the initial hæmorrhage was due to an abortion or not we were unable to determine, but we were inclined to put the patient's trouble down to that possibility with its frequent sequelæ of subinvolution bleeding, and in spite of the absence of any amenorrhœa and any other suggestions of pregnancy. If, however, deciduoma malignum is always the result of a conception—and if there was no conception in this case—then it is necessary to go back to the last pregnancy of some two years ago to account for the chorion-epithelioma.

Galabin has described three varieties of chorion-epithelioma; this specimen would seem to belong to the second variety of structure, with regard to which he says: "It is made up in about equal parts of syncytium—generally in large branching masses, and of masses of discrete cells. Large spaces containing blood are a marked feature of the growth, and the syncytium appears to lay open the blood-vessels in a manner which has been compared to the function of the syncytium in the development of the normal placenta."

FIG. 2.

Showing large mass of mature differentiated cells; large blood space; small branches of syncytium in the corner. $\times 250$.

The accompanying microphotographs, taken by the Clinical Research Society, show very well the structure detailed above—viz., branching masses of syncytium, masses of discrete cells, and the large blood spaces.

Ebbw Vale.

DEATH OF MR. SAMUEL LANDOR BENTON.—The death occurred with tragic suddenness at Lewes, on Sept. 26th, of Mr. Samuel Landor Benton, at the early age of 34. In practice at Lewes with Dr. W. A. Dow, who is engaged on military duties, Mr. Benton was deputising for his partner in his public appointments, and while working late at night he had a sudden seizure, and, despite all that medical skill could do, he passed away in a few hours.

SPINAL ANÆSTHESIA, WITH SPECIAL REFERENCE TO THE ACUTE ABDOMEN.

By PERCIVAL P. COLE, M.B., CH.B. BIRM.,
F.R.C.S. ENG.,

SURGEON, KING GEORGE HOSPITAL, AND WEST HAM AND EASTERN
GENERAL HOSPITAL; OPERATING SURGEON, BROOK WAR HOSPITAL;
ASSISTANT SURGEON, SEAMEN'S HOSPITAL, GREENWICH, AND THE
CANCER HOSPITAL, BROMPTON, S.W.

MY experience of this form of anæsthesia extends over a period of five years. For three years and a half I used the heavy, or Barker's, dextrose solution of stovaine, strength 5 per cent. During that time I limited its use to operations below the umbilicus, and rarely employed it for any abdominal operation other than appendicectomy and operations on the bladder. Eighteen months ago, acting on the advice of Mr. G. Ramsey Phillips, I abandoned the heavy solution, and have since used exclusively the Billon solution of stovaine in sodium chloride, strength 10 per cent. The advantages of the light over the heavy solution are as follows: (1) rapidity and constancy of action; (2) tilting posture unnecessary, thus allowing administration on any table, improvised or otherwise; (3) the head is kept lower than the feet throughout the operation; (4) the Trendelenburg position can be adopted as soon as the operator may wish; and (5) the higher average level of analgesia.

The operations performed with this form of anæsthesia include plating for fractured tibia and femur; fractured patella; removal of semilunar cartilage; varicose veins; skin grafting; amputations of lower extremity; hernia, femoral, inguinal, umbilical and ventral, strangulated and otherwise; varicocele; hæmorrhoids; removal of testicle; radical cure of hydrocele; internal urethrotomy; external urethrotomy; cystoscopy; cystotomy; prostatectomy; appendicectomy; hysterectomy; salpingectomy; cholecystostomy; perforated gastric ulcer; gastrostomy; and gastro-enterostomy. The ages of the patients have ranged from 6 months to 70 years.

The value of spinal anæsthesia in operations known to be attended by shock to the patient is generally recognised theoretically, and in this class of case its use is distinctly indicated. An interesting example was that afforded by a patient whose thigh I amputated through the hip-joint. This patient, a male aged 54, had a myxochondroma of the femur. He had long-standing aortic disease, and seemed a poor surgical risk. His pulse-rate never rose above 90, and the next morning he was reading the newspaper.

In operations on the urethra stovaine is, from the surgeon's point of view, ideal. Relaxation is so absolute that the difficulties are reduced to a minimum, and such a thing as impassable stricture ceases to exist. In a case of extensive extravasation of urine I was able, after making the usual free incisions, to perform an internal urethrotomy with excellent result.

In prostatectomy the method has been sufficiently emphasised by Mr. H. M. Page,¹ who has also recently contributed an article on its use in abdominal surgery.² Its rôle in this latter sphere demands further consideration. Here the psychic factor assumes added importance. It is the psychic factor which is, I believe, responsible for the prejudice which has limited and cramped the use of spinal anæsthesia. It is a fundamental principle, if success is to be attained, that psychic influences shall be reduced to vanishing point. Mr. Page accomplishes this by administering a small quantity of general anæsthetic. The same result can usually be obtained, less easily, I admit, by strict attention to technique.

It is essential to recognise that spinal stovaine is an anæsthetic and consequently should be administered by a competent anæsthetist, with all the ritual of a planned and considered performance. It is precipitating failure to usher forthwith a nervous patient into an operating theatre with its unaccustomed atmosphere and evidences of fearsome preparation. Before the puncture is made the mind is a prey to nervous fears and forebodings. Then perhaps follows an investigation as to the level of analgesia. Small wonder

is it that the patient so treated will feel things without being touched.

The technique recently adopted with complete success is as follows. A preliminary injection of morphia and atropine is given half an hour to one hour before the time fixed for operation. The spinal puncture is made in the anæsthetising room, the patient being told that she will not actually lose consciousness, but will be drowsy and will feel nothing. The eyes are bandaged, the ears plugged with cotton-wool, and suggestions are made that the patient goes to sleep. She is then wheeled into the operating theatre and lifted on to the table, and so arranged that the feet are higher than the head, this position being maintained throughout the operation. The towels are arranged and the field of operation is made ready. No testing to determine the level of analgesia is carried out, but the operator watches the face as he clips the towels to the skin. Absolute silence is maintained, not a word being spoken till the operation is completed. Instruments are handled with the utmost care, so that the clank of metal and the click of the artery forceps shall not be audible.

Operating under such conditions is good for everyone concerned; good for the patient, for it induces mental rest; good for the operator, for he must be gentle; good for the assistant, for he must be alert and intelligent; good for the theatre staff, for they must work accurately and smoothly.

Spinal anæsthesia has its indications in two distinct types of abdominal operations—operations of expediency and operations of urgency. Cases which have come under my care during the last few weeks will serve to illustrate such indications in the expedient class. In these cases the choice of anæsthetic was not a matter of indifference. General anæsthesia was definitely contra-indicated, and would in all probability have determined failure.

A very stout, middle-aged woman was admitted with a ventral hernia. I had removed her uterus 18 months before under a general anæsthetic. For a week afterwards she had vomited violently. Her abdominal muscles were poorly developed and the long-continued strain on the healing wound was, in my opinion, responsible for the development of her hernia. The patient was reluctant to undergo another operation, owing to her dread of this post-anæsthetic vomiting, and I was doubtful of success should it again occur. Stovaine was administered in the manner described, dose 7/10 c.c. Progress was quite uneventful, with no vomiting and no headache. When asked which anæsthetic she preferred, the patient emphatically decided in favour of stovaine.

A woman, aged 35, was admitted with pyloric stenosis. Two previous attempts at operative treatment had been made with a general anæsthetic. On the first occasion it was necessary to perform tracheotomy as soon as the abdomen was opened. On the second occasion urgent symptoms compelled the operator to desist before the abdomen was opened. Stovaine was administered and a posterior gastro-enterostomy performed without any difficulty. The influence of "team work" as a time-saving factor was also clearly demonstrated. The operation from spinal puncture to the last skin stitch was completed in 35 minutes. Three rows of sutures were used for the anastomosis. The abdominal wall was sewn up in four layers. The absolute flaccidity of the abdominal parietes is a revelation to those accustomed to operate on the upper abdomen under general anæsthesia only.

It is, however, in the surgery of the acute abdomen that spinal anæsthesia proves of still greater service. It is administered, too, in more favourable circumstances. These patients are in pain, and only too frequently have been so for many hours, perhaps for several days. The immediate relief afforded by spinal anæsthesia produces a mental attitude of tranquillity and confidence, and thus the psychic factor is effectually abolished. From the surgeon's standpoint the conditions for easy and expeditious operating are ideal. Relaxation is more complete than can be obtained with the most profound general anæsthesia; bowel, however greatly distended, shows no tendency to escape from the abdomen, and when displaced obediently maintains its position. A phenomenon which I have frequently noted deserves particular mention. In many cases of obstruction consequent to widespread peritonitis the bowels have acted on the table. This forcibly suggests that so-called paralytic ileus of inflammatory origin is not a true paralysis, but is due to an active inhibition, and that these inhibitory impulses are abolished by spinal anæsthesia. In one such case, following closely on an operation for acute

¹ THE LANCET, June 10th, 1916, p. 1169.

² Guy's Hospital Gazette, July 1st, 1916.

appendicitis, the patient was taken to the theatre for further operation. Stovaine was administered, but before the abdomen could be opened the patient vomited a large quantity of foul-smelling fluid, and the bowels acted copiously. Operation was deferred, but the obstruction recurred, for which jejunostomy was performed. It was later shown that this recurrent obstruction was mechanical, the terminal portion of the ileum being firmly bound to the pelvic floor by firm inflammatory adhesions. The significance of this observation as to the action of spinal anaesthesia on obstruction, due to spreading peritonitis, is sufficiently obvious. It implies that spinal anaesthesia should invariably be used in acute abdominal lesions associated with such conditions. It would seem, therefore, that this form of anaesthesia should be particularly useful in military abdominal surgery, and I strongly urge its claims in this connexion.

That patients whose condition is so bad as almost to preclude operation can be safely dealt with by this method is shown by the following cases.

A woman, aged 35, was seen in the casualty department of the West Ham Hospital. She had been ill for five days. The abdomen was greatly distended, rigid, and acutely tender. The patient's face was deathly pale; pulse-rate 160, scarcely perceptible. She was immediately taken to the operating theatre. Stovaine was administered and subcutaneous saline was run into both axillae. The face almost immediately lost its anxious, drawn look, and the patient dozed throughout the operation. A subumbilical median incision exposed inflamed coils of intestine stuck together by recent lymph. On gently separating the coils pools of pus were evacuated, this condition obtaining from the under-surface of the liver to the bottom of the pelvis. The cause of the peritonitis was a pyosalpinx. Both kidney pouches and the pelvis were drained by large rubber tubes. The operation lasted half an hour. The patient's pulse at the end was better than at the beginning. The bowels acted on the table. Slow but complete recovery was made.

Another patient was admitted for obstruction due to a very large and old-standing ventral hernia. She was 67 years of age and had been ill for four days, the vomit having become fecal. Stovaine was administered, subcutaneous saline started, and the operation commenced. The coils of gut were densely adherent to each other and to the sac wall. One coil, about 2 feet long, was found acutely strangulated, but as it showed signs of recovery it was replaced in the abdomen. The patient was perfectly quiet and placid throughout the operation, which lasted just over an hour. She developed a parotitis and an abscess at the site of injection of the saline, but otherwise made an uneventful recovery. The bowels acted copiously on the table.

The advantages of spinal anaesthesia to the operator are obvious and incontestable, and my experience leads me to urge that, particularly in the acute abdomen, the advantages to the patient are equally great.

Queen Anne-street, W.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON A CASE OF BERI-BERI.

By G. MARSHALL FINDLAY, M.B., CH.B. EDIN.,
TEMPORARY SURGEON, R.N.

THE following case of beri-beri presents certain interesting features in regard both to the history and the clinical symptoms of the attack.

The patient, aged 23, is a leading telegraphist in the Navy, and is of somewhat better education than the average naval rating. He entered the service in 1903 at the age of 16 and remained in home waters until February, 1911, when he was ordered to the Persian Gulf. Except for short intervals in Colombo and Bombay, he had spent the whole of the past five years in this part of the world. For the first seven months after arriving in the Gulf he remained in perfect health, but in September, 1911, he noticed that he was becoming weak and easily fatigued, and that his feet and legs were beginning to swell. He did not at this time complain of any cardiac symptoms, and apparently was entirely cured by three weeks' treatment in the sick bay. During the ensuing winter he contracted malaria while serving ashore, but was otherwise healthy. It was not until June, 1912, that signs of oedema again appeared in the feet and legs,

accompanied by shortness of breath, palpitation, and loss of deep reflexes—the classical signs of beri-beri. The patient spent four weeks in hospital and then returned to duty.

Throughout 1913 there was no recurrence of any of the symptoms, the patient attributing this to his having been in Colombo during the greater part of the year. It is an interesting fact that beri-beri was formerly very common in Ceylon; so much so that the word beri-beri is derived from an old Singhalese expression meaning weakness; now, however, it is rarely seen in the island. In September, 1914, while cruising in the Indian Ocean, symptoms of beri-beri again occurred, but completely disappeared after eight weeks' treatment in hospital. With the exception of a slight attack of malaria in the spring of 1915, the patient remained perfectly healthy until September of last year, when symptoms of the disease again appeared. As before the earliest signs were swelling of the feet and legs and loss of appetite. Later, cardiac symptoms began to develop, characterised by shortness of breath, pain and palpitation over the cardiac region.

In appearance the patient seemed well nourished, though very anæmic. There was marked swelling on the dorsum of the feet, round the ankles, and over the anterior aspect of the legs as high as the junction of the middle and upper thirds. A very slight swelling was also present for a short time over the forearms and hands. The affected areas were symmetrical on the two sides, while the oedema was of somewhat firmer consistence than that in Bright's disease. There was never any oedema on the chest or face.

Nervous system.—For the first few days of the illness the deep reflexes were exaggerated, but later they wholly disappeared and remained in complete abeyance for a period of three months. Then the knee-jerks reappeared, to be followed about one month later by the return of the Achilles jerks. At the present time—eight months after the onset of the illness—the knee-jerks are normal, while the Achilles jerks are still somewhat sluggish. Ankle clonus has never been present, and the superficial reflexes have always remained normal. There has been considerable impairment of cutaneous sensation on the dorsum of the fingers and toes, more particularly in regard to touch and pain. A peculiar numb feeling at the tips of the fingers was also complained of for a short time, but this has now completely disappeared.

There was considerable pain on grasping the calf muscles, and a similar symptom was present to a less extent in the muscles of the forearm. The muscular power was good, and at no time was there any evidence of wasting or of the reaction of degeneration. In the gait there was no true ataxia, although the patient habitually walked with his legs straddled and with a slight dragging of the feet. Foot-drop was absent. The "squatting test" described by Willcox¹ has been well marked and is still present. Rombergism is a striking symptom. The Argyll Robertson pupil, however, is absent, and there are no signs of any parasymphilitic lesion. The Wassermann reaction is negative. A certain amount of incoördination is still present, more particularly in the upper limbs; thus, with the eyes closed the patient is unable accurately to locate the tip of his nose. On the other hand, there is an entire absence of any intention tremor. There has never been any interference with the innervation of the oesophagus or larynx, a not uncommon symptom in beri-beri; the special senses also have all remained normal. The mental faculties are unimpaired.

Cardio-vascular system.—The symptoms referable to this system did not develop until about a week after the onset of the oedema. They consisted of shortness of breath, palpitation, and slight pain over the cardiac region. On examination the heart was found to be slightly dilated, more particularly towards the right side. The heart sounds were normal, though of a somewhat tic-tac character, while the spacing of the sounds gave rise to the peculiar pendulum-like rhythm described by Manson. The pulse was of low tension and easily compressible; it varied in rate from 80 to 100 per minute.

The alimentary system was normal except for the loss of appetite, while the urine never contained any abnormal constituent.

An interesting fact in regard to the above case is that during the two commissions which the patient served in the same ship there were no other instances of beri-beri among the crew. There is no apparent reason why he alone should have fallen victim to the disease. He is a teetotaler and a moderate smoker, and his diet consisted of the ordinary ship's ration, made up as follows: 1 lb. white bread or $\frac{1}{2}$ lb. biscuit; $\frac{1}{2}$ lb. fresh meat; 4 oz. preserved meat (twice a week); 1 lb. vegetables, usually potatoes and onions; 4 oz. sugar; $\frac{1}{2}$ oz. condensed milk; 1 oz. jam; and $\frac{1}{2}$ oz. tea. White rice, butter, and fish were all eaten occasionally, and lime-juice was issued every day. There is only one fact which points to a deficient diet as

¹ Willcox: Beri-beri, THE LANCET, March 11th, 1916.

having been the determining factor in this case—namely, that during the seven months previous to his first attack he never partook of any fresh meat. This defect was remedied after the first illness, without, however, preventing the recurrence of the disease.

There have thus been four attacks of beri-beri, all of the wet type, occurring at varying intervals, and characterised by a gradually increasing period of disability.

THREE CASES OF BELLADONNA POISONING.

By MARY E. JOLL, M.B., B.S. LOND.,

HOUSE PHYSICIAN, ROYAL FREE HOSPITAL, LONDON.

THE dangers of belladonna poisoning are well brought home by the following cases; *Atropa belladonna* is of fairly frequent occurrence within reach of children.

A boy, aged 6 years, was brought to the Royal Free Hospital on Sept. 16th in a condition of delirium. He staggered about talking to himself and making movements as of picking and eating things. His face was flushed and the eyes were widely dilated and not reacting to light. The tongue was dry and the pulse rapid, 156 per minute, and feeble. On inquiry it was found that he had eaten some berries in a public garden near by about four hours previously and since then had complained of dryness of the mouth and sickness, and had later become drowsy and would eat nothing. The symptoms pointed to belladonna poisoning, and the stomach was washed out. About 20 purple berries were found in the stomach contents. Two little girls, aged respectively 4 and 5 years, were also brought to the hospital within the next half hour with similar symptoms, though of less severity, and with a history of having eaten berries from the same garden. They were treated in the same way. All three children were admitted to the ward. The boy had to be sewn up in a blanket, as he was so restless. Pilocarpine nitrate, gr. 1/10 hypod., was given and hot bottles were applied to the feet. He became more delirious, tongue became drier, face more flushed, pulse more feeble, and temperature was slightly raised. More pilocarpine nitrate (gr. 1/6) was given, but he had no sleep. The next day the symptoms were even more marked; the child was still very delirious and vomited twice, the pulse was 150 per minute, and feeble, temperature 103.4° F., face flushed, and pupils were still widely dilated. A soap enema and pilocarpine nitrate, gr. 1/6 hypod., were given, and tinct. opii, min. iv., repeated once was given to procure sleep. The next day the temperature and pulse were down but the tongue was still dry and the face flushed. On the fourth day the tongue became moist but the delirium continued until the fifth day. On the sixth day the boy was discharged with pupils reacting only sluggishly. The two little girls recovered more rapidly, although the younger child vomited several times. In no case was there any diminution in urinary secretion.

A visit was made to the public gardens and four large fruiting shrubs of the *Atropa belladonna* were found. The gardener said that they had fruited there for many years and he knew them to be belladonna plants but thought them innocuous. It seems strange that with such free access other cases of poisoning have not occurred.

THE LONDON SCHOOL OF MEDICINE FOR WOMEN: OPENING OF NEW BUILDINGS BY THE QUEEN.—On Oct. 3rd, the date of the opening of the winter session for several of the London medical schools, the Queen opened an extension of the London (Royal Free Hospital) School of Medicine for Women in Hunter-street, W.C. Her Majesty was received by Miss L. B. Aldrich-Blake (Dean of the School), the Duchess of Marlborough (honorary treasurer of the Extension Fund), Mr. Acland, M.P. (chairman of the council), and Miss L. M. Brooks (the secretary and warden). Mrs. Garrett Anderson was absent owing to ill-health. The opening ceremony took place in the anatomical department, where Miss V. P. Thomas, the holder of the Queen's scholarship, presented a bouquet to Her Majesty. Miss Aldrich-Blake, in a brief historical address, stated that the school was founded by Dr. Sophia Jex-Blake in 1874, when the students numbered 14. In 1900 larger premises were built on the original site, and these had now been greatly extended. Miss Cullis, lecturer in physiology, having thanked the Queen for her presence and the interest which she had taken in the school, Mr. Acland presented a key to Her Majesty as a memento of the occasion. The Queen then declared the new buildings open. The cost of the extension, including equipment, has been £30,000, all of which has been subscribed, and the new building opens free of debt. The number of students at present on the roll of the school is 380.

Reviews and Notices of Books.

Refraction of the Human Eye and Methods of Estimating the Refraction.

By JAMES THORINGTON, A.M., M.D. London: William Heinemann. Pp. 407. Price 10s. 6d. 1916.

In the preface we are told that this "is an amalgamation of the author's works, 'Refraction and How to Refract,' 'Prisms,' and 'Retinoscopy,' so as to produce a book suitable for all beginners in ophthalmology, and particularly for those who have a limited knowledge of mathematics." In deference to these Dr. Thorington does not introduce a single mathematical formula, and consequently there is a lack of precision in his statements about lenses and prisms. As an instance we will quote a few lines on combined prisms (p. 48). Incidentally they will also illustrate his style.

Any two prisms, each less than 5V, of the same strength held in apposition and with their base-apex lines at right-angles to each other will equal or be equivalent to a single prism one or two units stronger than one of the prisms, with its base midway of the two bases. For instance, 5 prism-diopters base down meridian 45° combined with a 5 prism-diopter base down meridian 135° will equal a 7 prism-diopter base down meridian 90°.

What is the practical use of a vague statement like this? When is one unit instead of two to be added? What will be the effect of these two prisms when their base-apex lines (or their principal planes) are at any other than a right angle, and what if they are of an unequal strength?

The resultant effect, P, of any two prisms, *p* and *q*, in apposition, with their principal planes at an angle *α* between them, is given by two simple formulæ—

$$P = \sqrt{p^2 + q^2 + 2pq \cos \alpha},$$

and its principal plane is at an angle *θ* with that of *p*, when

$$\tan \theta = \frac{q \sin \alpha}{p + q \cos \alpha}.$$

If the reader's knowledge of mathematics does not permit him to follow these formulæ, it is useless for him to read about resultant prisms; he cannot understand how they act, nor can he prescribe them for his patients.

We are glad to see that Dr. Thorington advocates the use of a cycloplegic before testing the refraction by retinoscopy if reliable results are to be ensured, but he has no confidence in homatropine. He recommends his patients to use 1 per cent. atropine drops three times a day for two days before presenting themselves to him for retinoscopy. If, on the other hand, homatropine is to be used, one drop of a 2.5 per cent. solution is to be placed in each eye at bedtime.

The next morning one drop is to be placed in the eye every hour, from the time of rising until leaving home to go to the surgeon's office. At the office one drop is placed in each eye about every five minutes until six drops have been used; then, after waiting half an hour the refraction is carefully estimated (p. 299).

Most of us in England will think such a procedure unnecessary. On p. 351 the author states that the vision of an emmetropic (or of a corrected) eye under a cycloplegic which sees 6/6 will only see 6/60 with + 2.25 D. and only 6/12 with + 1.25 D.; in fact, that each .25 D. reduces the visual acuity by 1/10. The useful suggestion is that a guess can be often made as to the spherical lens required by noting the line of letters read.

The book is profusely illustrated with 344 figures, some of which are coloured, but a large number seem to be unnecessary. In the preface we read—

The writer has planned to be systematic and practical, so that the student, starting with the consideration of rays of light, is gradually brought to a full understanding of optics.

A mathematical subject cannot be understood without some knowledge of mathematics; the attempt may be daring, but it is doomed to failure. No allusion is made to Duane's excellent work on accommodation, which has recently taught us so much.

LIBRARY TABLE.

A Surgical Handbook for the Use of Students, Practitioners, House Surgeons, and Dressers. By FRANCIS M. CAIRD, M.B., F.R.C.S. Edin.; and CHARLES W. CATHCART, M.B. Edin., F.R.C.S. Eng. & Edin. Seventeenth edition. With 208

illustrations. London: Charles Griffin and Co., Limited. 1916. Pp. 364. Price 8s. 6d. net.—We noticed the sixteenth edition of this excellent handbook less than two years ago. Two pages, 327A and 327B, have now been interpolated in the appendix on Antiseptics in Time of War, describing Lister's curative antiseptic method in compound fracture, and the application of hypochlorous acid in the form of eupad and eusol to septic wounds. If the subject of antiseptics in war time had to be included at all we could have wished it to be more comprehensive in character. It is somewhat astonishing to find that the authors have so little to say on the subject of war surgery in what purports to be an up-to-date surgical handbook—there is, for example, no word concerning either tetanus or gas gangrene—but it is quite likely that the pressure of duties brought about by the war has taken from them all chances of the leisure necessary to collate the wealth of information that now is on record. The prophylactic injection of antitetanic serum is not even mentioned. The remainder of the book is unaltered.

The Eyes of Our Children. By N. BISHOP HARMAN, M.A., M.B. Cantab. *The Care of the Teeth.* By ARTHUR T. PITTS, M.R.C.S., L.R.C.P. Lond., L.D.S. *The Health of the Child.* By O. HILDESHEIM, M.D., B.Ch. Oxon. *The Health of the Skin.* By GEORGE PERNET, M.D. Paris. *The Care of the Body.* By FRANCIS CAVANAGH, M.D. *The Prevention of the Common Cold.* By OLIVER K. WILLIAMSON, M.A., M.D. Cantab. London: Methuen and Co. Price 1s. each.—These little volumes of Methuen's Health Series, the first six to appear, have been written with the object of giving the general public information which, if carefully applied, would add greatly to their health and happiness. Each book is complete in itself and deals, as will be seen from the titles, with a particular region of the body or a particular group of individuals. The appearance of the two volumes concerning children is appropriate at a time when special stress is being laid upon the preservation of child-life. Mr. Bishop Harman's book, in which instruction is given in an attractive manner, should be read by school teachers as well as by parents. The same applies to Mr. Pitts's book, for it is during school life that much preventive work may be done in safeguarding the teeth. The pernicious use of the "dummy" is graphically pictured on p. 70 by the reproduction of a photograph showing the resulting deformity. Dr. Hildesheim deals more with the health of the child in general and the hygienic measures essential to maintaining it. Dr. Pernet's little treatise may help in restricting the harmful use of cosmetics among the young girls to whom munition work has suddenly brought a liberal supply of pocket-money. Dr. Cavanagh gives much information which young workers especially might lay to heart with profit. In the last volume Dr. Williamson deals with a subject of perennial interest, though he does not claim to do more than lay down a code of life which will fortify the body against the common cold. Each book of the series is written in clear and non-technical language.

French and English Dictionary. Compiled by JOHN BELLOWS. Revised and enlarged by WILLIAM BELLOWS. London: Longmans, Green, and Co. 1916. Library edition, cloth, pp. 689. Price 5s. net. Pocket edition, leather, pp. 606. Price 9s. net.—The third edition of this admirable dictionary has made its appearance and will receive the same hearty welcome that has been accorded its predecessors. With all students of French Bellows's dictionary has been popular from the day of its first appearance in 1872 through all its editions and enlargements, for the scope of the work is very large, while the convenient size of issue makes the inclusive character remarkable. From the beginning the late John Bellows, the projector of the work, made the inclusion of technical renderings a special feature of the dictionary, and in continuing and developing these points his son, Mr. William Bellows, the present editor of the dictionary, has been industrious and energetic. Introductory notes acknowledge the good offices of many coöperators, among whom may be mentioned Professor G. Bonet-Mauray, whose practical help in the revision of the work has been extensive, M. Auguste Marrot and M. Gustav Friteau, professor of English at the Lycée Hoche, Brussels, the last two names figuring also on the title-page as collaborators with the editor. The manner in which in this dictionary the genders are distinguished, the indications for pronunciation and for the employment of liaison in French, as well as the brief grammatical schemes, are all alike useful, and we commend the book to the use of all our readers.

New Inventions.

AN IMPROVED BONE-DRILL.

THE accompanying illustrations represent a bone-drill which has been made for me from a design made by Dr.

FIG. 1.

FIG. 2.

G. Ramsey Phillips. As shown in Fig. 1, the drill is fitted into a chuck connected to a toothed wheel which is rotated by a chain stretched on a bow. Fig. 2 shows the drill in use. The great advantage of the instrument consists in the ease with which even the hardest bone can be drilled with the least possible exertion, especially in awkward positions in which the drive is not direct. I have used this drill in a large number of cases of bone-plating and have found it greatly superior to any other design. It is easily cleaned and the whole can be boiled for sterilisation.

Messrs. Allen and Hanburys, Limited, Wigmore-street, W., are the manufacturers.

R. H. JOCELYN SWAN, M.S. Lond., F.R.C.S.
Wimpole-street, W.

A MONOMOTIVE RHEOTOME.

THE above title is the name given by an American firm to a new interrupter of medical electricity currents. The apparatus is a kind of clockwork that moves a drum over which are fixed metallic teeth or pins. A movable lever is fitted over the drum and in its different positions the lever passes over 2, 4, 8, 12, 20, or 40 of those teeth or pins and gives 20, 40, 80, 120, 200, or 400 interruptions in the minute. This apparatus weighs about 4 lb., is quite portable, and free from the inconvenience of having to provide water or mercury as in nearly all other kinds of interrupters. The

weakest part is the spring which has not a uniform movement. After having been wound up the number of interruptions agrees with the number indicated upon the apparatus, but after some 15 or 20 minutes the number is reduced by half and it is necessary to re-wind it or move the lever to the next intersection. The feeling to the patient and the muscular contractions are about the same as with the metronome, and it is quite sufficient for ordinary medical work. The apparatus is manufactured by Mr. A. E. Dean, of Leigh-place, Holborn, London, the cost being less than £3.

THE LANCET.

LONDON: SATURDAY, OCTOBER 7, 1916.

The Future of the War Cripple.

THE problem of converting the fighting man who has been crippled in this war by sea or by land into a useful citizen again is one of appalling magnitude. It is not merely the numbers to be dealt with which constitute the difficulty, but the manysided nature of the problem, which cannot be effectively dealt with unless the several aspects are adequately studied. To do this without omission and without overlapping is a task which may well claim continuous attention from highly trained intellects. To us the difficulties appear to group themselves under three heads—administrative, material, and personal. With the first we are not, as medical men, very intimately engaged. But here one difficulty is both medical and crucial, and concerns the point at which the cripple shall pass from the military organisation into the civilian. So long as he remains in the Services he is the object of care of the hospital, the convalescent home, or the command dépôt. As soon as a Medical Board has decided that he is no longer physically fit for war service the cripple becomes a civilian entitled to a pension, and under the care of the Statutory Committee who pays him the pension. At this point the difficulty arises. The fact of his metamorphosis from soldier to civilian does not imply the desirability of any change in the cripple's treatment. On the contrary, it is of the utmost importance that the treatment should be continuous. It might conceivably be possible to duplicate all the appliances at present in use at command dépôts and convalescent homes—the baths, the mechanical apparatus, the workshops, and so forth—but it would unquestionably be impossible to obtain a duplication of the skilled medical staff to supervise the treatment. It is therefore an urgent administrative necessity that the treatment of the war cripple as soldier and as civilian should form a consistent whole. The Disablement Sub-Committee of the War Pensions &c. Statutory Committee has taken this view and has asked for opportunity to press it upon the Secretary of State for War. The medical profession is also taking action, and the proposal of the Committee of Reference of the English Royal Colleges to extend its purview to these matters was noted in our last issue and is one which we heartily welcome.

The second group of difficulties which we see in dealing with the problem of the war cripple is material, and concerns the means of restoration. The old experience of the man who practised with his artificial arm or leg for an hour or two and then threw it away, or wore it only for show, is not likely to be repeated under present conditions, but the artificial limb still leaves much to be desired. Dr. C. W. HUTT, in an article which appears elsewhere

in this issue, devotes a section to considering artificial appliances for the one-armed. He records the frequent French experience of the workman provided with a carefully devised implement, who places his artificial appliance on the table and works away with his sound arm and stump. The orthopædic staffs of our war hospitals are keenly alive to this situation, and scarcely a week passes without some improvement being introduced in the manufacture or the application of artificial limbs. The type of artificial arm hitherto in ordinary use is by no means as serviceable for all kinds of mechanical application as a simpler apparatus less resembling the real arm, but imitating with exactitude one or more of the actual movements essential to the particular work in hand. Such apparatus are now being devised not only in our own but also in enemy countries, as the pages of the most recent numbers of the military supplement of the *Münchener Medizinische Wochenschrift* abundantly testify. With a further aspect of this question, the provision of suitable occupations for men of various kinds and degrees of disability, Dr. HUTT also deals, and his paper may serve especially to direct attention to the intricacy of the adaptation necessitated. It is clear from his very interesting story that France is well to the front in this matter.

The third group of difficulties in regard to the future of the war cripple centres in many cases round the man himself. Nor is this to be wondered at. After the stress and strain of warfare, the monotony and confinement of illness and convalescence, the prolonged period of military discipline, the crippled soldier would be less than human if, on discharge from the Army, he did not sometimes prefer to draw his pension and to lead an existence free from exertion and ambition, rather than laboriously train himself for a new and perhaps uncongenial form of livelihood. From such a natural inertia has arisen the classical picture of the idle and drunken old soldier of bye-gone times. One potent factor in this melancholy direction has been the fear that any resumption of wage-earning capacity might imply a reduction in the pension to which the crippled soldier is entitled. Sir FREDERICK MILNER, whose work in the interests of the soldiers who have suffered for their country has been unceasing and wonderfully efficient, has rendered a public service in establishing the principle that no soldier shall forfeit any part of the pension allotted to him through making himself a useful citizen, and it is possible that a similar position ought to obtain in France, where one of the Directors of Instruction has put it on record that of 2000 men under his direction, only 350 were willing to learn a trade and to become self-supporting. We have more than once called attention to the part which the Local Statutory Committees under the War Pensions Act may play. By means of personal care and interest in each individual case they should be able to achieve results comparable up to a point to those obtainable by army discipline. We hope that this may be so. Much depends on the work of these Local Committees. In large measure the future of the war cripple as a useful citizen is in their hands.

The Commission of the Faculty of Insurance.

THE Commission instituted by the Faculty of Insurance to inquire into the general position of National Health Insurance, whatever else it may achieve, will make clear many of the points at which the Insurance Acts in their working are most open to criticism and attack. Whether all the opinions of witnesses before the Commission will be accepted by those who have no hostility to the Acts, but only desire to see the fullest possible advantage obtained from them for the public, is another matter. We make, however, here the suggestion that no drastic change of the present system is likely to be inaugurated; at any rate, it will not come until longer experience of National Insurance has taken place under more normal conditions than now prevail. We do not regard, for example, the repeal of the Insurance Acts as within the region of practical politics, or think that such repeal would be largely welcomed either by the public or the medical profession; nor is a change in the system of payment from that under which the medical man is remunerated according to the number of insured persons undertaken likely to be generally introduced. That in many matters affecting the medical profession conditions are unsatisfactory and might be improved is evident, but we are hardly inclined to anticipate agreement on the part of the legislature, with the criticism of a medical witness at Manchester that "the Government made a huge blunder when it handed over the administration of sickness and maternity benefits to Approved Societies." Whether we agree or no with the situation reached, we regard the societies as being for the present in possession of an assured position, and for the time being we believe harmonious coöperation with them, with the definite intent of securing the patient's good, to be the object to be aimed at. If at some future date failure to attain that object can be established, and can be proved to be due to the action of the societies, then, no doubt, their participation in insurance administration would be endangered. These, however, are examples of changes of a revolutionary character which are not likely to be brought about until longer experience has shown them to be necessary; the nation's experience of insurance in time of peace had been of comparatively brief duration when a war intervened, the future effects of which can hardly now be estimated.

There are points, nevertheless, upon which the Commission has bestowed attention, where improvement may fairly be demanded, even though it may not immediately follow. As to these a considerable measure of unanimity may be expected, at any rate on the part of the medical profession, but delay in reform will be due to the financial difficulty which is now accentuated. The sum provided for drugs is inadequate to the extent that at any time a medical man may find himself surcharged, if he prescribes as he would do in the case of a patient who paid for his own medicines. Many medical men are making

larger incomes than they did before they were on the panels, and have every right to do so, for their increased emoluments represent greatly increased work. The point, however, is reached in districts insufficiently supplied with practitioners that too many patients have to be attended in the day to permit sufficient time to be assigned to all of them. The Acts have not been long enough in force to show whether this may some day be remedied by the law of supply and demand. Even then it would be evident that a higher rate of pay will secure more efficient treatment for the patient, by increasing the supply of medical men and by enabling them to make a proper income out of less congested lists. The evidence as to maternity benefit has shown that in many cases it fails entirely to secure the object for which it must be taken to have been instituted. It is apparently habitually devoted in some districts to paying arrears of rent, and in no way tends to promote the physical good of the mother and her infant. Other instances might be given in which attention has been directed by the Commission, not indeed to newly discovered subjects of possible improvement, but to points where reform is genuinely needed, and where effort to obtain it must be made, at any rate when peace returns. The evidence of Mr. MORRIS, secretary of the London Hospital, taken at an early stage of the Commission's proceedings, has been among the most interesting yet heard. Speaking upon a subject strictly within his own experience, he was able to say that the income of his hospital had not suffered through National Insurance, and that an important source of revenue—the collections held by workmen—had not diminished. His evidence was also of importance as to the effect produced by the Insurance Acts upon the work of a great metropolitan hospital. He said that trivial cases treated in the hospital and sent home had diminished by 50 per cent., and that the number of out-patients had appreciably diminished. On the whole, he was satisfied that a multitude of slight cases were now dealt with by medical men on the panels, thus leaving the hospital free for more serious cases. This is one of the results which, it was hoped originally, would be brought about through National Insurance. Progress in this direction has been delayed through the absence of so many medical men from their practices under the conditions of war now prevailing, but this movement in the right direction should later be resumed.

Otherwise, however, than as a means of securing the record of opinions and facts for consideration and future discussion, such an inquiry into panel practice as that instituted by the Faculty of Insurance can hardly be expected to secure definite results at the present time. An enormous number of the working population, in whose interests the Acts were passed, are abroad or absent from their normal occupations on war service. The opinions and experience of these through representatives approved by them are not available; and neither in its broader principles nor in detail is National Insurance likely to be reconstructed without consultation of those most

concerned. The medical profession, equally interested, is in the same position as the patients. It is taking its part in the great war wholeheartedly, and it neither has the opportunity to formulate opinions upon the topics raised, nor, in the case of those on active service, the power to come forward and express them. Moreover, the members of the medical profession actively engaged in the Navy and Army include a preponderating proportion of younger men who have recently entered the medical profession, and who, above all, are interested in the future conditions of their career. National Insurance, with its merits and demerits, is being worked in circumstances which render criticism altogether unsatisfactory and inconclusive. Literally thousands of panel practitioners are away from their practices, and their colleagues are struggling to cope with the needs of the civil population, insured and uninsured. No system of medical service upon a large scale for the benefit of the working classes could yield results under such conditions which would not be open to unfavourable estimate in some aspects, and it is impossible to discuss the past working of the Act, either from the point of view of the public or the medical profession, without remembering that it is more than two years since war was declared. In those two years much might, and certainly would, have been done in the direction of amendment and alteration, which must now be postponed until we have peace; and, it must be added, until we are able to realise the position in which peace will find us. Financial, political, social, and economic conditions will not then be the same as in 1914, and all these things will have to be taken into consideration. The Commission of the Faculty of Insurance will have done all that can be expected of it when it has collected and issued evidence for our future guidance. With regard to the points of interest to the medical profession, that evidence will be useful if it assists in the formulating of a definite policy upon each of the various questions raised—if, that is to say, it helps individual members of the profession towards unanimity and towards combining to obtain under a National Insurance scheme an improved medical service for their patients and a satisfactory position for themselves.

MEDICAL MEN AS LEGISLATORS.—Of the 47 members who compose the new Legislature of British Columbia, elected recently, six are doctors.

DONATIONS AND BEQUESTS.—By the will of the late Miss Sarah Broom MacNaughtan, the well-known novelist and traveller, the testatrix left £1,000 to the Hospital for Women, Euston-road. Miss MacNaughtan had been a devoted ambulance worker since the war broke out in Belgium, France, and Russia, and her life was sacrificed to the hardships which she underwent.

ST. BARTHOLOMEW'S HOSPITAL MEDICAL SCHOOL.—The following awards of entrance scholarships at this school have been announced:—1. Entrance scholarship in Arts of the value of £100 for one year awarded to E. H. Weatherall, of the Bolton Grammar School, Bolton. 2. Senior entrance scholarships in Science, value £75 each for one year, awarded to C. F. Krige, of Hertford College, Oxford, and A. G. Shurlock, of Jesus College, Cambridge. 3. Junior entrance scholarship in Science, value £150 for one year, awarded to C. H. Andrewes, of Highgate School.

Annotations.

"Ne quid nlmis."

THE CAMPAIGN AGAINST VENEREAL DISEASE.

FREE post-graduate courses of instruction in the diagnosis and treatment of venereal diseases at the Military Hospital, Rochester-row, Victoria, S.W., have been arranged by Lieutenant-Colonel L. W. Harrison, D.S.O., R.A.M.C., in conjunction with the Panel Committee for the County of London. The London County Council are making arrangements with several of the metropolitan hospitals to establish special out-patient clinics for the treatment of persons suffering from venereal diseases. It is expected that facilities will be afforded for general practitioners in the neighbourhood of the hospitals to coöperate in the work of these clinics. Practitioners on the panel will desire to prepare themselves for taking an active part in the treatment of cases of syphilis and gonorrhœa following on the return of our armies by attendance at one of the courses. The first four weeks' course will consist of three lectures and practical classes by Lieutenant-Colonel Harrison at 3 o'clock on Tuesday, Wednesday, and Thursday, Oct. 10th, 11th, and 12th. The set demonstrations will be given each morning at 11.30 and continue till 1. The departments are open to the class from 10.30. The rota of the attendance at the practical classes in the three succeeding weeks will be arranged, as far as possible, to suit the convenience of the members as indicated in the particulars given on the form of application. Tickets of admission and further particulars can be obtained only from Dr. Richmond, Secretary of the Panel Committee for London, Staple House, 51, Chancery-lane, W.C.; applications should not be made to the Military Hospital.

PUBLIC BATHS IN NORWAY.

WITH the support of the Norwegian chief medical officer and the assistance of many Norwegian medical men, Dr. C. Römcke, has published¹ a full account of the facilities for obtaining baths enjoyed by the members of the public in Norway, both town and country. Among 55 of the chief towns, with populations varying from Christiania's 250,000 to Svelvik's 1000 inhabitants, all but five have public bath-houses, apart from baths for the school-children. The public bath-houses may be either communal or of private ownership, and may provide hot baths of three varieties, the douche bath, the tub bath, or the bath in a bath-room. The douche bath is naturally the cheapest, costing in various localities from 1*d.* to 3*d.*; the bath-room bath comes next in cost, and may be had at various prices, in accordance apparently with the amount of service given by the attendants. Thus at Christiania one may spend from 2½*d.* to 2*s.* 6*d.* on a public bath-room bath. The tub-bath has the highest minimum price, about 6*d.* in many places; experience shows that the men prefer the bath-room, while the women prefer the more private tub-bath. Many towns are provided with cellar school baths for the school children; thus at Christiania there are 21 schools and 21 school baths, and in 44 Norwegian towns there are 124 schools with 48 school baths and 14 hired baths between them.

¹ Tidsskrift f. d. Norske Lægeforening, Christiania, 1916, xxxvi., 726.

In other towns the school-children have access to the public baths; in some instances at the public expense. Dr. Römcke remarks that the internal arrangements of many of these baths leave much to be desired; it is essential that each child should have a cubicle for undressing and dressing, and until this rare provision becomes general it will not be possible to enforce a weekly or fortnightly hot bath for each child. Naturally, therefore, baths at home are widely used by men, women, and children alike. In the country the provision of public hot baths is less satisfactory than it is in the towns. The chief problem is the heating of the water; the expense here is often lessened by attaching the baths to establishments already provided with furnaces or boilers. Thus, Dr. Römcke tabulates 81 factories with baths attached, 25 dairies, 8 mines, 6 institutions; he also details 34 public baths, 31 school baths, 23 nursing homes and 21 homes for the aged with baths, in Norwegian country districts. He expresses surprise and regret at the small number of the public baths attached to the many dairies in the country, and notes that the public baths can rarely be self-supporting institutions; he advises that they should be financed by the public authority or the savings banks. He adds that public electric supplies are common, but that the electric heating of water for public baths is not a practical proposition at present, speaking generally, although it may be found in large electricity works and in some private houses. It is a curious fact, considering the geography of the country, that the proportion of Norwegians who can swim is small, the number of deaths in Norway from drowning being about 600 a year. Only about 12 per cent. of all the school-children between the ages of 12 and 15 have learnt to swim; the percentage of swimmers is low in the public schools, but higher in the board schools where the children between 10 and 15 years of age must have at least 20 hours' instruction in swimming. This instruction is given partly in water, we are told, and partly on land—the so-called dry-swimming! In June, 1913, 65 courses of instruction in swimming were given to some 1550 school-children in Christiania; only 850 of them learnt how to swim.

THE PLUMBER AS MUNITION MAKER.

FOR the obvious reason that good, faithful, scientific plumbing forms one of the greatest protections to a community from the spread of infectious disease we take a real interest in the work of the Plumbers' Company, and we noted last year that under the ægis of the Company many plumbers were working at the manufacture of shells. In normal times the labour sufficient to deal with the required output of such material is associated in the Union of Lead-burners, but the limited numbers of this union proved quite inadequate for the work when war broke out. The organisation of the Plumbers' Company throughout the country proved then of valuable assistance to the Ministry of Munitions, for in the plumber the country had a munition worker nearly trained. With the help of the Lead-burners Lodge of Canning Town some hundreds of plumbers have been instructed in this very technical work, and have not only met our own needs, but many have been drafted to the help of the Allies. The plumbers naturally proved apt pupils; they were trained either at the Laboratory of the Plumbers' Company at King's College or at the Technical School of the London County

Council at Brixton, the London County Council entering heartily into the work promoted by the Company. At the Guildhall on Sept. 20th a special Court of the Plumbers' Company was held under the Mastership of Mr. W. D. Caroe, M.A., R.I.B.A., to offer the Company's thanks and congratulations to representatives of the Operative Lead-burners and Plumbers who had so willingly contributed to a result so satisfactory, also to bestow the Freedom of the Company upon Mr. W. H. M. Smeaton, himself a plumber, and late secretary to London Council for the Registration of Plumbers, on his appointment by the Indian Government to the post of inspector of plumbers at the Royal Cordite Factory of the Madras Presidency. The process of lead-burning, hitherto confined to a very limited number of men, is one essential to the production of the plant necessary for chemical industries. Especially is it so in the dyeing trade for long monopolised by Germany, which it is hoped will, under Government encouragement, be revived in this country.

CHORION-EPITHELIOMA.

IN the great majority of cases a chorion-epithelioma owes its origin to a previous pregnancy, normal or abnormal. The frequency with which these tumours are preceded by a hydatidiform mole proves that there is some causal relationship between the two conditions. In how many cases a chorion-epithelioma is likely to follow a mole of this description is a more difficult question to decide, and the data we have at our disposal for answering it are rather scanty. Of 22 cases observed for varying periods up to 20 years, in only 2 did the patients die from a condition which might have been a chorion-epithelioma, while in 13 per cent. of another series of 49 cases such a condition may have supervened. The figures proving the relationship of pregnancy to chorion-epitheliomata are more definite. Thus, of 455 collected cases in only 6 was the occurrence of a previous pregnancy at all doubtful, while in 12 of the cases the pregnancy had been situated in the tube. The primary site of the tumour may be the uterus—the most common—or it may occur in the tube, or it may even originate outside the genital tract in a detached placental embolus. In a few of the recorded cases many years have elapsed since the last pregnancy and the menopause even may have intervened; for example, two cases of this kind have been published—in the first the last pregnancy had occurred ten years before and the patient was 11 months over the climacteric, while in the second the last abortion had taken place 21 years previously and the menstrual periods had ceased for one year. Even in the absence of amenorrhœa, we cannot assert that a married woman has not had an early abortion, and it is generally impossible to prove that a woman who develops a chorion-epithelioma has never been pregnant. We publish in this issue the notes of an interesting case of chorion-epithelioma under the care of Dr. H. Neville Taylor. There is another variety of these growths, much less frequently met with, in which the tumours occur in the neighbourhood of, or in the tissue of, the ovary or of the testis. These tumours occur quite independently of pregnancy, and represent the class of chorion-epitheliomata developing in various kinds of teratomata. In some instances undoubtedly they are examples of malignant degeneration in

the tissues of a teratoma, while in other cases there is little but the malignant growth to be recognised and the exact nature of the tissue from which it originated cannot be determined. Now that our knowledge of the embedding of the early ovum is so much more complete, it is evident that this type of new growth forms a most striking example of a physiological function which has, so to speak, run riot. The early trophoblast has the power of destroying the maternal tissues, and in this way the developing ovum embeds itself in the tissues of the uterus or of the tube, and provides for its early nutrition. The maternal tissues are supposed to protect themselves from undue damage by the development of the decidual cells, and the special liability of the tube to be damaged extensively may be explained by the relatively poor development of the decidua in this situation. In the case of a chorion-epithelioma this destructive power of the foetal cells has developed to such an extent that it acquires a malignant character and ultimately leads to the death of the host. Why in any given case the epithelial cells of a hydatidiform mole should be capable of this destructive action we are entirely ignorant. We do, at any rate, know that such a catastrophe is, happily for the patient, of rare occurrence. The secondary deposits in a case of chorion-epitheliomata, more frequently than in any other kind of malignant tumour, not infrequently disappear. Cases have been recorded in which such growths in the vagina or vulva have sloughed out, and instances are not infrequent in which patients presenting the physical signs of secondary growth in the lungs have ultimately completely recovered. Another curious problem connected with these tumours is the relation to them of the lutein cysts of the ovaries, which are so often met with. Ovarian cysts also may occur which are not of lutein origin, but whether this is more than a mere coincidence is uncertain. That the small lutein cysts will shrink and disappear after the removal of the mole seems certain, but we are not aware of any evidence that ordinary ovarian cysts accompanying such tumours will do the same thing. No doubt one day the problem will be solved, when our knowledge of the internal secretions of the ovaries is more perfect; in the meantime, we can only collect facts and wait for the complete elucidation of the causation of this particular variety of cancer in women. All cases should be most carefully noted and reported.

THE "PHARMAKOS."

In an article contributed to *Folk-lore* Mr. Morley Roberts deals learnedly with the "Pharmakos" or Scape-Goat of the ancient Greek festival celebrated in the month of May and known as the Thargelia. At this festival, according to the *Lexicon of Harpocration*, *sub voce Pharmakos*, quoted by Sir James Frazer in the "Scapegoat" volume of the "Golden Bough," two victims, one to represent the men and another the women, were led out at Athens and stoned to death in order to avert evils and purify the city. As a rule, says Frazer, when speaking of Greek custom at large, "when a city suffered from plague, famine, or other public calamity, an ugly or deformed person was chosen to take upon himself all the evils which afflicted the community. He was brought to a suitable place, where dried figs, a barley loaf, and cheese were put into his hand; these he ate. Then he

was beaten seven times upon his genital organs with squills and branches of the wild fig and other wild trees, while the flutes played a particular tune. Afterwards he was burned on a pyre of wood of forest trees; and his ashes were cast into the sea." Mr. Morley Roberts is chiefly concerned with the philology of the word "pharmakos," which is related to "pharmakon" (medicine), but in its original sense had no connexion with the idea of drugs or remedies; it referred rather to a custom in use among primitives of driving out evil spirits, such as those of disease, with a whip or with blows. The Greek word *pharmakos* was probably of foreign origin. Something very similar to it is found in the Turkic tongues, where *vourmak* means "to whip"—compare with the Latin *verber*. The root *vour* seems to have been the same in both the Turkic and so-called Aryan groups of languages. Thus in Greek "pharmakeuo" means "I give drugs or poisons," but anciently, Mr. Morley Roberts writes, it probably "implied an early medicine man, a Shaman, something equivalent to those found with all their ritual among the Africans and Central Asians. Thus *pharmakeuein* means, as it would with early races, 'to drive out evil spirits with a whip, or with blows.' Such a connotation is, on my theory, earlier than 'to give poisons,' but one knows that the ritual of the savage cure largely consists in driving out the spirit of disease or witchcraft by noisy incantations or by actual physical ill-usage of the patient." Thus trephining among savages has been held to be a mode of expelling an evil spirit or noxious foreign body from the head, and "pharmacist" had perhaps for an early meaning "exorcist." All over the East the word *farmaçion* is in use to denote "an outlaw," and Mr. Roberts believes that "*farmaçion*" is actually the same word as *pharmakos*.

THE NATIONAL MISSION.

In November next the various religious bodies into which this nation is divided will unite in a National Mission, whose object is to rouse the people to a more vivid realisation of its spiritual life. Repentance and Hope are the twin watchwords of the Mission, the part played by Repentance being based on the dictum that even when we have done our all we are still unprofitable servants; and the Hope is that when we emerge from the furnace of war we shall find ourselves purified and strengthened for the never-ceasing fight against selfishness, luxury, and class divisions. No nation ever has risen to and endured in greatness without religion, and we may define "religion" in its widest sense in the words quoted by Mr. Warde Fowler as "the effective desire to be in right relation to the Power manifesting itself in the universe."¹ The literature of two of the great nations of antiquity has preserved for us the expression of this feeling. In the forty-fourth Psalm, which presumably was written during or in allusion to the Antiochan persecutions, the writer says, after recounting the national sufferings:—"And though all this be come upon us, yet do we not forget Thee; nor behave ourselves frowardly in Thy covenant." Again, in the year B.C. 390 the city of Rome was sacked and burned by the Gauls, and a movement was set on foot to desert the ruined city and move to Veii. The speech of Camillus, as

¹ Warde Fowler: *The Religious Experience of the Roman People*, p. 8; Macmillan, 1911.

given by Livy (Book V., cap. 51), in opposition to this course, shows how even then violation of the law of nations was looked upon as wrong, and "religion" was regarded as the guide. The great Roman points out that the Roman people had disregarded an oracular prediction, that their ambassadors had outraged the law of nations, and, still worse, that the people had condoned the outrage; therefore, he says, judgment had fallen upon the city. But he proceeds: "Deorum cultum, deserti ab Diis hominibusque, tamen non intermisimus"—deserted as they were by gods and men yet the Divine worship continued to be carried on. Our own land, our capital, and our people have not as yet suffered to so great an extent as the ancient Romans or the Jews, or, indeed, so much as many of our Allies, and yet there is scarcely a house in this country where there is not some association with one lost or sorely stricken, while the mass of us is daily facing death in the cause of righteousness and of a lasting peace. It is for those who have to stay at home to do their part not merely in the active work of munition-making, not only in conducting with all their might the business of the country, and not only in seeking every opportunity for succouring those whom fate has hit more hardly than themselves; we must cultivate "self-reverence, self-knowledge, self-control," and the sure way here is through the development of the spiritual side of ourselves. That this development has already begun is obvious to anyone who has eyes to see—the bounteous charity that has been instituted on all sides and the disappearance of class differences are alike the proofs. It is possible, though difficult, to have a healthy mind in an unsound body—witness the many saints, both ancient and modern, who have been weakly of physique. But it is impossible to have a really healthy body with an unsound mind. Hence, from the physician's point of view the National Mission should be welcomed, while the meeting should not be of those "conscious of each other's infirmities," but of those conscious of their own.

THE Harveian Oration of the Royal College of Physicians of London will be delivered before the College on Wednesday afternoon, Oct. 18th, by Sir Thomas Barlow, formerly President of the College.

A CONFERENCE of Local Medical and Panel Committees, convened by the Insurance Acts Committee of the British Medical Association, will be held in the Crown Room of the Connaught Rooms, Great Queen-street, Lincoln's Inn Fields, W.C., on Thursday, Oct. 19th, at 10 A.M. The conference will be continued on the following day if the length of the proceedings renders this necessary.

At the first autumn meeting of the Medical Society of London on Oct. 9th, the incoming President, Lieutenant-Colonel D'Arcy Power, will deliver an address on "John Ward and His Diary." Other discussions and papers already arranged are: Oct. 23rd, Mr. David McCrae Aitken, demonstration of cases illustrating Orthopaedic Principles and Methods in Military Surgery; Nov. 3rd, discussion on Epidemic Nephritis, introduced by Captain Langdon Brown; Feb. 12th, Surgeon-General H. D. Rolleston, R.N., paper on Naval Medicine in the Great War. In each case the time is 8.30 P.M. The Lettsomian lectures will be delivered by Colonel Cuthbert Wallace, A.M.S., and the oration by Sir William Osler.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Local Government Board and Substitutes of Military Age.

THE Local Government Board has recently issued a circular letter to boards of guardians dealing with the subject of the employment of substitutes who are of military age. The Board recalls that last November it advised boards of guardians that vacancies occurring after that date in the Poor-law Medical Service should not be filled permanently until the termination of the war, and that in the interval the best temporary arrangements should be made for the discharge of the duties of such offices. Unfortunately, it has happened that in many cases guardians have employed as their temporary officers newly qualified practitioners eligible for military service. Similar appointments were frequently made in the case of substitutes for medical officers who had temporarily left their districts for service with the Royal Army Medical Corps. The Local Government Board now reminds boards of guardians that the demand of the military authorities for young medical men is still urgent, and that guardians should avoid giving any inducement to medical men of military age to seek civil work. The Board suggests that where a vacancy occurs, the guardians should assign the post to a medical man holding a permanent local appointment, or the duty might be divided between two or more such medical officers. Only as a last expedient should a separate medical officer be temporarily appointed, and then the selection should as far as possible be limited to doctors who are over 45 years of age, or otherwise ineligible for military service. The guardians should invite the co-operation of their medical officers in this matter and request their views as to the best means for filling the temporary vacancies for the period of the war.

The Numbers of the Insured.

The impossibility of estimating, with any approach to accuracy, the number of insured people in any given insurance area is a source of much trouble, since both the sanatorium and the certification grants are distributed on the basis of such numbers. The county or county borough index of insured gives an exaggerated as well as an incorrect estimate, since it includes persons who have moved into other areas as well as soldiers. It is believed that the indexes exaggerate the true numbers by about 25 per cent. For instance, at the last monthly meeting of the County Armagh Insurance Committee the clerk mentioned that there were 27,528 insured persons in County Armagh on the books, but the Insurance Commissioners in the amount credited to the County Insurance Committee for the treatment of cases of tuberculosis were only allowing for 20,480. The Commissioners have not stated the grounds on which their estimate is based, and it is natural that both insurance committees and medical men are concerned at the apparent shortage in the grants.

The Notification of Pulmonary Tuberculosis in Belfast.

Attention was drawn in your columns a fortnight ago to the fact that in the July returns of infectious diseases there was only one notification of tuberculous phthisis in Belfast, while it would seem that many cases of pulmonary tuberculosis were being treated in various Belfast institutions. The public health statistics dealing with the week ending Sept. 16th and the week ending Sept. 23rd present the same curious feature. In Dublin during the former week there were 50 notifications of tuberculous phthisis, while only 1 case was notified at Belfast; in the second of the two specified weeks there were 46 notifications of tuberculous phthisis in Dublin and only 1 in Belfast.

An Outbreak of Enteric Fever in Co. Roscommon.

An outbreak of enteric fever has recently occurred at Hillstreet in the Carrick-on-Shannon No. 2 rural district of the County Roscommon. So serious has it been that the police authorities have been obliged to close the barracks, and to remove their men from the district. It was found that all the persons affected had obtained their drinking water from wells which were liable to surface contamination of both animal and vegetable origin. Mr. P. F. Doorly, the medical officer of health, had previously drawn the attention of the sanitary authority to the necessity of providing a pump for the use of the

inhabitants of the village. Professor E. J. McWeeney, on his bacteriological examination of the samples of the public water-supplies at Hillstreet, condemned one sample outright, regarded with suspicion two of the four samples supplied to him, and considered the fourth a "border-line" water. In face of this bacteriological report and of the strong representations of the Local Government Board, the rural district council, as local sanitary authority, made an order that in its opinion the water-supply of Hillstreet was adequate, and that the fever had been imported into the district. It remains to be seen what steps the Local Government Board will take to compel the local authority to carry out its duties.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Sanitary Squads in the Army.

THE Under Secretary of State for Military Hygiene has arranged for the immediate appointment in each district of so-called sanitary squads, to be attached to the armies in the field with a view of effectively applying the methods of hygiene and public health in camps and cantonments. Each squad is to include 15 men of the auxiliary service chosen from the youngest age-groups. On the technical side, under the command of an auxiliary pharmacist, the squad will be furnished with a staff comprising a sergeant and two corporals. The men of these squads will receive special instruction, theoretical and practical, in the general hygiene of troops in the field, especially as regards the following points: disinfection of dwellings, white-washing, disinfection of privies and closets, the care of the manure-heap, measures against flies and stinging insects, incineration of excreta, baths, destruction of lice, putrefaction, and protection of drinking water. Each member of the squad will, as far as possible, be specially trained in one item of the programme in order that he may, when necessary, direct a fatigue party which has received no hygienic instruction. The squads will exercise special and continuous supervision in places where troops are continually on the move. Arrangements have been made to bring this new sanitary measure into force by Oct. 15th.

Death of Dr. Valentin Magnan.

The death has recently occurred, at the age of 80 years, of Dr. V. Magnan, one of the most illustrious and venerated names in contemporary French psychiatry. Born at Perpignan, resident officer in hospitals at Lyon in 1858 and Paris in 1863, he was appointed to the Asile St. Anne in 1867, and for more than 40 years continued to occupy this post. Magnan possessed the gift of unusual clinical discernment and of exact description, and his efforts to establish a rational classification of mental disorders bore fruit. His clinical and systematic lectures in the Asile attracted many students and still more qualified men. He was a great teacher. The principal works which established his fame were on mental degeneracy, chronic delirium, *folie intermittente*, epilepsy, aphasia, alcoholism, and absinthism. In 1893 he was elected to the Academy of Medicine in the Section of Hygiene and Forensic Medicine, and of the latter he became President. On the forensic side he was firm, penetrating, and luminous. To him is due the generalisation of the method of no-restraint. He liberated from cellular confinement and the strait-jacket nearly all the violent patients under his care, and by means of systematic attention produced a great improvement in their condition. His method has been universally followed in France.

Antityphoid Vaccination in the French Navy.

M. Chantemesse has communicated to the Academy of Medicine the results obtained from antityphoid inoculation in the French Navy, where preventive inoculation is compulsory. In a group of 80,000 men vaccinated completely or incompletely, 136 cases of typhoid or paratyphoid occurred, with 10 deaths (7 per cent. mortality). In a group of 60,000 non-vaccinated, 525 cases of the same diseases occurred with 77 deaths (14 per cent. mortality). M. Chantemesse's present practice is to prepare complete vaccinal doses of typhoid and paratyphoid bacilli, incorporating them in an oily solution composed of sesame oil, a little oleate of cholesterin, and purified neutral lanolin. With this preparation only one injection is necessary, and the resulting immunity lasts one to two years. The injection is painless.

THE SERVICES.

ROYAL NAVAL MEDICAL SERVICE.

Deputy Surgeon-General J. L. Smith, M.V.O., to be Surgeon-General.

Fleet-Surgeon J. H. Stenhouse to be Deputy Surgeon-General.

ARMY MEDICAL SERVICE.

Surgeon-General T. J. O'Donnell, C.B., D.S.O., to rank as Lieutenant-General whilst employed as Director of Medical Services in India.

Lieutenant-Colonel A. K. Kennedy, R.A.M.C., to be Colonel, vice Colonel J. C. Morgan.

ROYAL ARMY MEDICAL CORPS.

The undermentioned relinquish their temporary rank on re-posting:—Lieutenant-Colonel (Temporary Colonel) M. Boyle, Lieutenant-Colonel (Temporary Colonel) N. Tyacke, Captain (Temporary Major) P. S. Stewart, and Captain (Temporary Major) W. E. Marshall.

The undermentioned to be temporary Colonels whilst Assistant Directors of Medical Services of Divisions: Lieutenant-Colonel T. K. Maurice, Lieutenant-Colonel W. H. S. Nickerson, V.C., C.M.G., Lieutenant-Colonel F. S. Penny, C.M.G., Brevet-Colonel H. Ensor, D.S.O., and Lieutenant-Colonel P. MacKessack.

Major E. E. Powell, from supernumerary list, to be Lieutenant-Colonel.

Temporary Lieutenant-Colonel W. P. G. Graham relinquishes his commission on account of ill-health.

Captain R. E. Todd is restored to the establishment.

The undermentioned temporary Captains to be temporary Majors: J. B. Stephens and G. H. Ross.

Temporary Captains relinquishing their commissions: N. Black, F. R. Featherstone, M. McK. McRae, and T. D. Jago.

Temporary Lieutenants to be temporary Captains: F. K. Kerr, J. C. Walker, and H. S. Raper.

Temporary Lieutenants relinquishing their commissions: J. T. Bowman, D. A. Volume, D. L. Dick, C. T. Galbraith, E. M. Pearse, B. F. Keillor, A. P. Robertson, W. Girdwood, F. C. Stewart, J. F. Wood, J. F. Lambie, L. B. Burnett, and Carl W. Von Bergen.

F. D. Saner to be temporary Lieutenant.

R. A. Holmes to be temporary Honorary Lieutenant whilst serving with No. 8 British Red Cross (Baltic and Corn Exchange) Hospital.

TERRITORIAL FORCE (R.A.M.C.).

Eastern General Hospital: Captain H. M. Galt resigns his commission.

South Midland Field Ambulance: Lieutenant E. G. Anderson to be Captain.

London Sanitary Company: Lieutenant W. Johnstone to be Captain.

Supernumerary for service with the Officers Training Corps.—Lieutenant A. Macphail to be Captain.

Attached to Units other than Medical Units.—Captain S. Southam relinquishes his commission on account of ill-health.

TERRITORIAL FORCE RESERVE (R.A.M.C.).

Major W. V. Sinclair, from London Field Ambulance, to be Major.

JOURNAL OF THE ROYAL ARMY MEDICAL CORPS.

The September number of this journal opens with an interesting paper on Inoculation and Infective Agglutinins Determined by Absorption Methods, in which the author, Professor I. Walker Hall, who had the assistance of Mr. I. L. Hiles, M.Sc., and Mr. F. Nichols, records some of the results of a routine examination of cases of paratyphoid fever in the relation between the immunity obtained by prophylactic methods and that conferred by disease. A short note on Weil's Disease (Spirochaetosis Icterohæmorrhagica), as it has occurred in the army in Flanders, is contributed jointly by Captain Adrian Stokes and Captain John A. Ryle; a Report on the Later Results of Gunshot Wounds of the Head, by Lieutenant-Colonel P. Sargent and Lieutenant-Colonel G. Holmes, states, as one of the chief conclusions, that there are no grounds for supposing that more radical operations abroad are called for; and a paper on the Extent and Nature of the Sensory Loss in Musculo-spiral Paresis, by Lieutenant J. Renfrew White, deals with a matter which has received some attention during the war. In a series of 20 cases of injury to nerve-trunks of the upper limbs collected by the writer during the earlier months of the war, the musculo-spiral was involved in six cases; in half of these it was the only nerve to suffer, in the other three there was a concomitant injury to at least one other trunk. The current issue also contains a further contribution by Dr. E. C. Hort and Captain A. H. Caulfield (C.A.M.C.), on Epidemic Cerebro-spinal Fever: the Place of the Meningococcus in its Etiology.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 96 English and Welsh towns with populations exceeding 50,000 persons at the last Census 7505 births and 4480 deaths were registered during the week ended Saturday, Sept. 30th. The annual rate of mortality in these towns, which had steadily increased from 10.5 to 12.8 per 1000 in the six preceding weeks, further rose in the week under notice to 13.5 per 1000 of their aggregate civil population, estimated at 17,312,295 persons for the year 1915. During the 13 weeks of the quarter just ended the mean annual rate of mortality in these towns averaged 11.4, against 11.1 per 1000 in London. Among the several towns the death-rate last week ranged from 3.2 in Ealing, 7.2 in Warrington, 8.0 in Tottenham, 8.1 in Northampton, and 8.5 in Exeter, to 19.0 in Sunderland and in Southport, 19.7 in Tynemouth, 20.4 in St. Helens, 21.1 in Gateshead, and 24.8 in Wakefield.

The 4480 deaths from all causes were 236 in excess of the number in the previous week, and included 488 which were referred to the principal epidemic diseases, against 594 and 548 in the two preceding weeks. Of these 488 deaths, 384 resulted from infantile diarrhoeal diseases, 40 from diphtheria, 23 from measles, 20 from whooping-cough, 11 from enteric fever, and 10 from scarlet fever, but not one from small-pox. The annual death-rate from these diseases was equal to 1.5, against 1.7 per 1000 in the previous week. The deaths of infants (under 2 years) from diarrhoea and enteritis, which had been 457, 477, and 448 in the three preceding weeks, fell to 384, and included 90 in London, 40 in Liverpool, 19 in Birmingham, 15 each in Manchester and Hull, 13 each in Leeds and Sheffield, and 12 in Bristol. The deaths attributed to diphtheria, which had been 47, 35, and 39 in the three preceding weeks, were 40 last week, of which 8 were registered in London and 3 in Birmingham. The fatal cases of measles, which had declined from 50 to 21 in the four preceding weeks, slightly rose to 23, and included 9 in London and 2 each in Birkenhead and Sheffield. The deaths referred to whooping-cough, which had been 28, 33, and 28 in the three preceding weeks, fell to 20; 3 deaths occurred in London and 2 each in Birmingham, Sunderland, and Gateshead. The deaths attributed to enteric fever, which had been 7, 9, and 4 in the three preceding weeks, rose to 11, of which 2 were registered in London. The fatal cases of scarlet fever, which had been 4, 11, and 8 in the three preceding weeks, rose to 10, and included 2 in Newcastle-on-Tyne.

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had been 990, 980, and 1012 at the end of the three preceding weeks, rose to 1020 on Saturday last; 151 new cases were admitted during the week, against 142, 130, and 158 in the three preceding weeks. These hospitals also contained on Saturday last 1294 cases of diphtheria, 91 of measles, 63 of whooping-cough, and 36 of enteric fever, but not one of small-pox. The 1114 deaths from all causes in London exceeded the number in the previous week by 146, and corresponded to an annual death-rate of 13.5 per 1000. The deaths referred to diseases of the respiratory system, which had increased from 66 to 109 in the four preceding weeks, further rose to 131 in the week under notice.

Of the 4480 deaths from all causes in the 96 towns, 215 resulted from violence, 390 were the subject of coroners' inquests, and 1316 occurred in public institutions. The causes of 45, or 1.0 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, Hull, and in 68 other smaller towns. Of the 45 uncertified causes, 8 were registered in Birmingham, 7 in Leyton, 5 in Liverpool, 4 in St. Helens, and 2 each in London, West Bromwich, and South Shields.

HEALTH OF SCOTCH TOWNS.

IN the 16 largest Scotch towns with an aggregate population estimated at 2,372,000 persons at the middle of this year 975 births and 661 deaths were registered during the week ended Saturday, Sept. 23rd. The annual rate of mortality, which had been 14.3, 13.1, and 13.0 per 1000 in the three preceding weeks, rose to 14.5 per 1000 in the week under notice. During the 12 weeks of the current quarter the mean annual death-rate in these towns averaged 12.5, against 11.2 per 1000 in the large English towns. Among the several towns the death-rate during the week ranged from 6.4 in Kirkcaldy, 9.2 in Falkirk, and 11.1 in Motherwell, to 16.0 in Clydebank, 17.1 in Ayr, and 18.1 in Greenock.

The 661 deaths from all causes were 70 in excess of the number in the previous week, and included 104 which were referred to the principal epidemic diseases, against numbers

declining from 88 to 72 in the three preceding weeks. Of these 104 deaths, 83 resulted from infantile diarrhoeal diseases, 6 from whooping-cough, 5 from diphtheria, 4 from measles, and 3 each from enteric fever and scarlet fever, but not one from small-pox. The annual death-rate from these diseases was equal to 2.3, against 1.7 per 1000 in the large English towns. The deaths of infants (under 2 years) from diarrhoea and enteritis, which had been 61, 56, and 50 in the three preceding weeks, rose to 83, and included 60 in Glasgow, 7 in Edinburgh, 6 in Dundee, and 3 in Greenock. The deaths referred to whooping-cough, which had been 3, 5, and 7 in the three preceding weeks, were 6 in the week under notice, of which 3 occurred in Glasgow. The fatal cases of diphtheria, which had been 9, 6, and 6 in the three preceding weeks, numbered 5, and comprised 2 each in Glasgow and Edinburgh and 1 in Aberdeen. The deaths attributed to measles, which had been 8, 10, and 4 in the three preceding weeks, were again 4, but showed no excess in any particular town. The fatal cases of enteric fever were recorded in Glasgow, Aberdeen, and Ayr, and those of scarlet fever in Glasgow, Edinburgh, and Perth respectively.

The deaths referred to diseases of the respiratory system, which had been 57, 45, and 49 in the three preceding weeks, rose to 62 in the week under notice, but were 24 below the number registered in the corresponding week of last year. The deaths from violence numbered 41, against 25 and 27 in the two preceding weeks.

IN the 16 largest Scotch towns 987 births and 618 deaths were registered during the week ended Saturday, Sept. 30th. The annual rate of mortality, which had been 13.1, 13.0, and 14.5 per 1000 in the three preceding weeks, fell to 13.6 per 1000 in the week under notice. During the 13 weeks of the quarter just ended the mean annual death-rate in these towns averaged 12.6, against 11.4 per 1000 in the large English towns. Among the several towns the death-rate during the week ranged from 4.6 in Falkirk, 5.7 in Clydebank, and 6.9 in Coatbridge, to 15.4 in Greenock, 16.5 in Dundee, and 16.8 in Kilmarnock.

The 618 deaths from all causes were 43 below the number in the previous week, and included 75 which were referred to the principal epidemic diseases, against 72 and 104 in the two preceding weeks. Of these 75 deaths, 50 resulted from infantile diarrhoeal diseases, 9 from diphtheria, 6 from scarlet fever, 5 from measles, 4 from enteric fever, and 1 from whooping-cough, but not one from small-pox. The annual death-rate from these diseases was equal to 1.6, against 1.5 per 1000 in the large English towns. The deaths of infants (under 2 years) from diarrhoea and enteritis, which had been 56, 50, and 83 in the three preceding weeks, fell to 50, and included 35 in Glasgow, 3 each in Dundee and Greenock, and 2 each in Edinburgh and Aberdeen. The deaths attributed to diphtheria which had been 6, 6, and 5 in the three preceding weeks, rose to 9, and included 3 each in Glasgow and Paisley. The fatal cases of scarlet fever, which had been 5, 3, and 3 in the three preceding weeks, rose to 6, of which 2 occurred in Glasgow. The deaths referred to measles, which had been 10, 4, and 4 in the three preceding weeks, numbered 5, and included 3 in Glasgow. The 4 deaths attributed to enteric fever were 3 in excess of the average in the earlier weeks of the quarter, and were recorded in Dundee, Aberdeen, Greenock, and Kilmarnock respectively. The fatal case of whooping-cough was registered in Edinburgh.

The deaths referred to diseases of the respiratory system, which had been 45, 49, and 62 in the three preceding weeks, further rose to 72 in the week under notice, but were 21 below the number registered in the corresponding week of last year. The deaths from violence numbered 25, against 37 and 41 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

IN the registration area of Dublin 181 births and 139 deaths were registered during the week ended Saturday, Sept. 30th. The annual rate of mortality, which had been 14.8, 17.3, and 15.6 per 1000 in the three preceding weeks, rose to 18.3 in the week under notice, against 13.5 and 14.7 per 1000 in London and Glasgow respectively.

The 139 deaths from all causes included 36 of infants under 1 year and 31 of persons aged 65 years and upwards. Seventeen deaths (of infants under 2 years) were referred to diarrhoeal diseases, 4 to enteric fever, and 1 each to scarlet fever, whooping-cough, and diphtheria. The causes of 4 deaths were uncertified, and 58, or 42 per cent., of the total deaths occurred in public institutions.

During the same period 180 births and 100 deaths were registered in the city of Belfast. The deaths corresponded to an annual rate of 13.4, or 1.2 per 1000 less than in the previous week, and included 11 of infants under 1 year and 29 of persons aged 65 years and upwards. Six deaths were referred to infantile diarrhoea, 2 to scarlet fever, and 1 to enteric fever. The causes of 4 deaths were the subject of coroners' inquests, and 1 other was uncertified, while 28 of the total deaths occurred in public institutions.

Correspondence.

"Audi alteram partem."

THE CHOICE OF ANÆSTHETIC FOR A MILITARY HOSPITAL.

To the Editor of THE LANCET.

SIR,—I am glad to reply to Colonel J. Campbell's letter in THE LANCET of Sept. 30th. First, may I explain that my letter in the issue of Sept. 16th was written somewhat hurriedly on the eve of my going on holiday? I can quite imagine that the type of patient met with in a base hospital in France is not the same as we get here. The exhausted, anæmic, and septic men Colonel Campbell speaks of are not at all numerous with us, and our men are mostly of the robust type, although their wounds are all more or less septic. I should not dream of using chloroform for such cases; I give them ether. I have found, however, that the men do better, as a rule, under chloroform than under any other anæsthetic. We have here a large number of "clean" operations, such as for hernia and varicose veins, nerve and blood-vessel operations, and we have a large throat, nose, and ear department, as well as an eye department, with many cases requiring plastic operations. With 2500 beds we have to get through our work rapidly and have no time to spare for what I may perhaps be allowed to call fancy anæsthetics.

My routine method in this hospital is to induce with C.E. (CHCl, 2, ether 3) until the stage of excitement is passed and then continue with chloroform by the Junker apparatus. Should any signs of depression appear I sprinkle some ether on the mask, but this I have rarely found necessary. Space does not permit of my going into much detail, but I hope I may at some time have an opportunity to do so.

To mention a few of my cases:—

Appendicectomy.—Five difficult cases, in all of which administration lasted over an hour, an ideal smooth anæsthesia, perfect relaxation being obtained in all. One shorter one, administration lasting 36 minutes, in which chloroform was given from the first with ideal result. Formerly I always gave ether for this operation after a preliminary hypodermic injection of morphia and atropia.

Nerve operations.—One in which administration lasted 1 hour 44 minutes. Two on brachial plexus, in one of which administration lasted 3 hours 20 minutes, a preliminary hypodermic injection of 1.100 gr. atropia being given; induction by chloroform for 3 minutes; ether by close Clover for 7 minutes, the rest of the time chloroform being given by Junker's apparatus and a good even anæsthesia maintained. The other lasted 2 hours 40 minutes.

Bone-plating, femur.—Administration lasting 1 hour 57 minutes.

Amputation of thigh.—Administration lasting 42 minutes; in this case 6 per cent. glucose solution was given per rectum every four hours for 48 hours before operation.

Removal of a piece of shell from spine; complete paraplegia.—Administration lasting 63 minutes. Position fully prone.

Whether or not my method is regarded as obsolete, I have found it advantageous to the patients, the surgeon, and myself. It is undeniably simple and economical. I am daily employing it, and intend to continue. If given carefully, in suitable cases, by an experienced anæsthetist, I do not believe that the risks of chloroform are much greater than those of any other anæsthetic. I believe it would be practically impossible to obtain the apparatus required to carry out some of the methods mentioned by Captain Wilkins, in the average military hospital dependent on the War Office for its supply. I consider the Vernon Harcourt apparatus bad in principle since the patient has to draw all his air-supply through narrow tubes.

With regard to the letter of my esteemed colleague, Dr. H. L. Noel-Cox, in THE LANCET of Sept. 23rd I have to express my regret that, in the hurry of the moment, I omitted to acknowledge his valuable suggestions for the mouth-prop and tube. I had no desire whatever to claim credit for an invention, but merely wished to direct attention to the instrument.—I am, Sir, yours faithfully,

A. DE WINTER BAKER.

Horton County of London War Hospital, Epsom, Sept. 30th, 1916.

To the Editor of THE LANCET.

SIR,—The recent correspondence on this subject reminds one of the motor aphorism: "Every automobilist has three

speeds—viz., that which he tells the police he is driving at; the one he mentions to his friends; and lastly that at which he really drives." These stages likewise exist with the anæsthetist. Thus: the one the surgeon remarks on; the one the patient comments about (on the following day); and the one the administrator believes the patient to be in. These three, like the motorist's speed, do not always coincide!

The choice of an anæsthetic in a military hospital, as well as in a civil hospital, must be judged after consideration of the patient's condition and the nature of the operation. That one man's meat is another's poison, certainly applies to anæsthetics. A good test is an induction without struggling, an unconsciousness without cyanosis, both ideal for the patient as well as more pleasant for the administrator. Some may attain this in one way, others in another. It is not the anæsthetic; it is the way it is given. With some a bit of lint and a drop-bottle of chloroform will achieve this; others prefer more accurate methods, such as the simple percentage chloroform inhaler which I described in THE LANCET of April 1st, or the warmed vapour methods advocated by Dr. F. E. Shipway, of Guy's Hospital. When rapidity of induction is an important point, as in a casualty clearing station, the ethyl chloride-ether sequence has much to commend it, especially when used as by my colleague Captain Cronyn, with an Ormsby inhaler.

The tests on which I should insist are: a quiet induction, a good colour, and an absence of post-anæsthetic sickness. The anæsthetic which gives these results, plus the relaxation the operator needs, is the ideal one. Personally I believe this to be obtainable with the simple percentage chloroform inhaler, in long cases giving ether after chloroform induction through the pot. Eleven per cent. can be obtained with the indicator fully on and a higher percentage of ether is obtainable by attaching a few layers of gauze to the air intake and dropping on ether. Oxygen can be given at the same time by slipping into the air-intake a pewter tube connected with a cylinder of oxygen. I find this method of great use for prolonged chloroform anæsthesia such as cases of laminectomy, nerve resection, abdominals, and operations of two hours or more.

I am, Sir, yours faithfully,

CHARLES T. W. HIESCH,

Temporary Captain, R.A.M.C.: Anæsthetist, Royal Herbert Hospital, Woolwich.

Kensington Palace-mansions, W., Oct. 2nd, 1916.

THE EFFECT OF FERRIVINE AND INTRAMINE ON SYPHILIS.

To the Editor of THE LANCET.

SIR,—It was partly in view of the unknown impurities, which modify the action of the organic preparations salvarsan and neosalvarsan that I attempted to avoid having to use arsenic. So long as we use compounds containing one or more of the only three metals which have a strong bactericidal action *in vitro* but not *in corpore*—namely, arsenic, antimony, and silver—we are playing with fire, because the greater the bactericidal action a metal has the more toxic it is. Ferrivine was stated to be colloidal, which it is, because of the size of its molecule, of the properties it exhibits when examined by the ultramicroscope, and of its readiness to form ferric hydroxide when injected intravenously. I have stated that the hydroxides of both aluminium and iron have a therapeutic action in syphilis, but it is necessary to protect them by an emulsoid colloid before they can be injected intravenously. Ferric hydroxide being an unstable colloid, I prepared ferrivine, which readily forms the hydroxide on reaching the blood-stream. It is owing to this property and to the result it sometimes has in causing shock that made it necessary to add a protective. Unfortunately, as I have since found, the more protected a colloid is the less therapeutic action it exerts. To get over this difficulty it will be necessary to prepare a compound with the iron more firmly attached to the benzene ring. If such a compound can be prepared I am confident that, with the joint use of intramine, our treatment of syphilis will be more successful and less dangerous than it is with salvarsan and its substitutes.

I am, Sir, yours faithfully,

London, Sept. 30th, 1916.

J. E. R. McDONAGH.

A PLEA FOR ROUTINE RADIOSCOPY IN MILITARY HOSPITALS.

To the Editor of THE LANCET.

SIR,—In the course of two years' work with the X rays in French military hospitals in this district I have been much struck by the number of cases in which results of the first importance have been obtained although the patient was submitted to X ray examination almost accidentally. Many of the hospitals here are not fitted with X ray installations and in only a comparatively small number of cases are the patients sent for examination to a hospital where an installation does exist. Inevitably, also, these cases are those in which the medical man in charge has some suspicion that there may be either a bony lesion or a foreign body present. The frequently surprising results obtained from these "fortuitous" cases make one think the radioscopy examination of all, even possibly, surgical cases ought to be as much a matter of routine as taking the names of the patient and his regiment.

I have often noticed that men have been sent back from the front with their papers recording a diagnosis made at a base hospital or an X ray examination made and perhaps a projectile removed. In many of these cases the diagnosis seems to be taken as final, or in cases where an X ray examination has been made it is assumed that all the possible information which such an examination can give has been given and acted upon. That this is not always a safe assumption the cases I cite below seem to prove, and they are only four striking examples among many I have met with. They seem to indicate that the more leisurely examinations possible outside the zone of the armies may lead in many cases to information which will result in a much shortened stay in hospital.

CASE 1.—Sergeant-Major —. A man of about 38. Ten months at the front. Frequently employed on especially dangerous and responsible work. No wound. Was crawling along a communication trench under heavy shell-fire. On reaching his destination found he could not straighten his knee without pain. Sent to base hospital and treated for some time for rheumatism. Then evacuated to interior and arrived at this hospital. Had never been X rayed. On examination by me it was found he had a piece of a needle about 1 inch long just below the left patella. It was easily localised and extracted in operation.¹

CASE 2.—Soldat G —. (Wounded Sept. 8th, 1914.) His papers stated he had been hit by a machine-gun bullet which entered his left buttock and passed out at a point just above the left popliteal space. After the wounds had healed patient complained of pain, which led to his having electrical and other treatment for sciatica and paralysis of the left foot for 4½ months. The pain having lessened, he was sent to his dépôt for convalescence; but the pain having returned, he was sent here for galvanism. On April 8th, 1915, our surgeon, Dr. Roger Cope, removed a mitrailieuse bullet from the very substance of the sciatic nerve itself. Another bullet, deeply embedded near the hip-joint, as it was causing no trouble, was left. The explanation, of course, was that he had been hit simultaneously by two bullets, and that what had been assumed to be entrance and exit wounds were in reality two entrance wounds.

CASE 3.—Soldat V —. His papers showed that he had been hit by an *éclat d'obus* in the left forearm, near the wrist. The ulna was fractured. A large piece of shell had been removed from the wound, and was in the man's possession. He was sent in to me from another hospital for a report on the condition of the fracture. This was good, but a radioscopy examination showed a rifle-bullet near the elbow. As there was only one entrance wound the bullet and the shell fragment must have entered simultaneously at the same place. As the probe revealed the *éclat d'obus* and accounted for a not very serious fracture, no X ray examination had been deemed necessary.

CASE 4.—Soldat C —. Wounded by an *éclat de grenade*, June 9th, 1915. In this case there was a large and fairly superficial wound in the left lumbar region. He had been X rayed at a base hospital and a large piece of grenade casing had been extracted. On re-examination, on reaching us, it was found that there was a group of foreign bodies in the region of the wound. They were quite small and almost transparent to the X rays. There was no fracture. Mr. F. W. Ramsay

¹ I should mention that his fellow patients were full of derision for this mishap, and said that it was not a war wound, it was a charwoman's accident. In saying above "no wound," I am quoting the man's own answer to my inquiry. He subsequently said that he supposed as he was much scratched and had many insect-bites that it was invisible, and being under shell-fire he cannot have noticed a needle-prick.

operated and removed from the wound 14 fragments of bone. Now, as there was no fracture it is plain that somewhere in its flight the projectile had encountered bone, had smashed it to atoms and driven the fragments into the patient's back. A cursory screen examination had revealed the large projectile which had been removed. Its very obviousness had veiled the other faint shadows which the unburied routine work revealed. I very much doubt if this case would even have been sent in for examination from another hospital here, at any rate not until it had suppurated for a long time.

I am, Sir, yours faithfully,

E. W. HUTTON (Mrs.),

Chef du Service Radiologique, H.C. 95, St. Malo; L'Hôpital Notre Dame des Grèves, St. Malo, I. et V., France.

Sept. 27th, 1916.

THE TREATMENT OF SEPTIC WAR WOUNDS.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Sept. 16th, p. 507, Colonel Sir Almroth Wright has the following sentence: "It would defy anybody to picture to himself the 'tissues assembling forces (chiefly cells).'" I venture to suggest that, on the contrary, the local assembling of tissue cells as a means of defence against microbic invasion is a matter which has been too much neglected by immunologists. What is a lupus nodule or a syphilitic papule but an assembling of tissue cells as a defence against microbic invasion? And does not the familiar wart result from an assembling of epithelial cells as a defensive reaction to the invasion of some as yet undiscovered microbe? I would ask Colonel Wright to read an illuminating article by Dr. R. Sabouraud in the *Annales de Dermatologie et de Syphiligraphie*, t. x., 1899, p. 729, entitled "La Défense de la Peau Contre les Microbes." There is described a "tableau de bataille" which clearly contradicts Sir Almroth Wright's seeming assertion that the cells of the tissues take no part in reactions of defence.

I am, Sir, yours faithfully,

Devonshire-place, W., Sept. 27th, 1916.

H. G. ADAMSON.

MEDICAL CERTIFICATES AND FITNESS FOR MILITARY SERVICE.

To the Editor of THE LANCET.

SIR,—The differences of opinion as regards a man's fitness for general service between the military medical officers and the civilian practitioners are greatly to be deplored and deprecated, as they tend to undermine the confidence of the public in the skill of the medical profession. Any solution which would obviate these disagreements would be an advantage. There are faults on both sides, but they do not lessen the gravity of the disagreement. The civilian practitioner practically is bound to give to a patient a certificate, but he words it in such a way that an intelligent military medical officer should be able to read between the lines. The military medical officer should avoid making any disparaging remarks on the nature of the certificate. It would, however, be far better if the War Office were to issue a form similar to the forms used for life assurances or in accordance with the examination of recruits, and these completed forms would be given to the individual to hand to the President of the Medical Board. They would be of great assistance to the military medical officers in forming a correct decision and would remove all causes for complaint. A civilian practitioner never is aggrieved at an adverse decision to his opinion by the medical officers of a life assurance.

I am, Sir, yours faithfully,

G. SHERMAN BIGG, F.R.C.S. Edin.,
Surgeon-Captain, A.M.S. (retired).

Victoria-street, S.W., Oct. 1st, 1916.

THE TREATMENT OF ANGIO-NEUROTIC OEDEMA.

To the Editor of THE LANCET.

SIR,—I should be very obliged if any of your readers can help me in treating a case of angio-neurotic oedema, or giant urticaria. I myself am the case.

The history is as follows. When about 16 years of age and a medical student the trouble began, and lasted on and

off for about a year or so and then disappeared, and I forgot all about it. Now, 20 years later, it has returned to be a burden to me. Two years ago I came out to India and was stationed in a very hot district, and the urticaria returned. Six months ago I was sent to a cooler station and it left me, but has again returned. The malady takes the form of raised patches of erythema, varying in size from a patch 1 or 2 inches square to areas of 6 or 8 inches. After riding I may get a very marked patch on the inner aspect of the knees and a less raised patch all the way down each thigh on the inner side; a frequent place is the flexor aspects of the forearm, but the worst area is when the soles of the feet become affected. In this position it is very painful, due to the tension, and walking is a misery. After a long march, say 12 miles, it may come on, but as long as one keeps going it is bearable, but if a rest is taken it is agony to get going again; if, however, I "stick it" the pain seems to wear off, only to return on again resting. Yesterday I had to ride a distance of 20 miles, and to-day my gluteal region, thighs, feet, and calves are, to say the least of it, distressing.

The "eruption" is distinctly cedematous in character, and anything tight in the way of gaiters laced tightly or sock suspenders will induce it. Lying out on the ground at night in camp will for a certainty bring out the "bumps" on the hip or back. The malady has affected the scrotum and penis; in the latter it is usually unilateral, and the first time I experienced it I thought I had a severe but painless balanitis! The swellings gradually appear and extend, and last as a rule for 48 hours; they are not very irritable, but scratching is interesting, so to speak. Pain is only marked in areas such as the palms of the hands and soles of the feet. As a medical student I woke up one night feeling stuffy and uncomfortable in the throat, and found that one side of the uvula and palate was cedematous and causing some embarrassment in breathing; it passed off by the morning. I only once have had it on the face, the upper lip; once I had melæna during an attack, pointing to the possibility of the intestinal mucous membrane being the seat of a patch.

My general health is excellent, and has always been. I am very abstemious, never drinking spirits or beer; I smoke a good deal. I am unable to trace the onset of the attacks to diet, but suspect nuts, and hence avoid them. It is interesting, however, that three days before the present attack I ate three chocolates containing walnuts.

There is no hereditary history of a disposition to the disease. I am married, with one child; eat well, sleep like a top, and work hard, and always have done. My family history is good and without medical interest.

I have got no satisfaction at all from text-books either as to pathology or treatment; and apart from advice from a skin specialist to keep a tracheotomy tube always ready, no other recommendation has influenced me. I feel quite well in every other way before and during an attack.

I shall be very grateful if any of your readers will advise me as to a cure for this "distressing complaint." As I write this my right hand is half as big again as my left; to-morrow it may be the other way round.

I am, Sir, yours faithfully,
MAJOR, R.A.M.C. (T.F.).

India, Sept. 1st, 1916.

THE CASES OF PLAGUE IN LIVERPOOL.—The outbreak of plague in Liverpool was brought to light owing to the death of a boy on Sept. 19th. The patient had been medically treated for double pneumonia, but died after two days' illness. The father and brother of this boy became ill about the same date and were removed to the workhouse, and the circumstances were reported to the medical officer of health. The two latter patients were examined and isolated in hospital, as they presented symptoms suspicious of bubonic plague. This diagnosis was confirmed later by bacteriological examination. The mother was also taken to hospital as a contact and developed the disease about Sept. 22nd. The father died on Sept. 21st. In the family affected, therefore, there were four cases and three deaths. Investigations showed that there had been a previous death in the family, as a daughter had died on Sept. 8th, the cause of death being stated to be "ptomaine poisoning." A suspicious case in another family was reported on Sept. 27th. The patient was at once isolated in hospital, and died two days later. The illness in this case has been confirmed bacteriologically as bubonic plague. Up to Oct. 2nd nothing further had occurred, the total cases numbering five, with three deaths. The origin is ascribed to rats.

The War.

THE CASUALTY LIST.

THE following names of medical officers appear among the casualties announced since our last issue:—

Killed.

Capt. G. V. Bogle, New Zealand Medical Corps, qualified M.B., Ch.B. Edin. in 1912, and after holding an appointment at the Royal Infirmary, Edinburgh, he went out to New Zealand, and was in practice at Hawkes Bay before joining the New Zealand contingent.

Lieut.-Col. A. N. Walker, R.A.M.C., was educated at Cambridge University and at the London Hospital, and qualified in 1898. He was a well-known Liverpool ophthalmologist, and had made several contributions to medical literature on the diseases of the eye.

Capt. G. P. Selby, R.A.M.C., was educated at Winchester and at Oxford University, and was a student at St. Bartholomew's Hospital, London, qualifying in 1914. He served in Bulgaria in a British Red Cross unit during the Turco-Bulgarian War, and joined the R.A.M.C. in July, 1914, going to the Front in the following December.

Died of Wounds.

Capt. J. Deighton, R.A.M.C., attached King's Own Royal Lancaster Regiment, was educated at Cambridge and at the London Hospital, and qualified in 1914.

Capt. O. G. Parry-Jones, R.A.M.C., was educated at Sherborne and at Oxford, and was a student at Guy's Hospital, London, qualifying in 1915.

Died.

Major A. H. Benson, R.A.M.C., officer commanding a Mounted Brigade Field Ambulance, was educated at Radley and at Cambridge University, and qualified in 1887. He was in practice at Cleobury Mortimer, Salop, before joining the R.A.M.C., and had been connected with the Auxiliary Forces for some years. He served throughout the South African War, and was mentioned in despatches.

Wounded.

Capt. J. A. Andrews, R.A.M.C., attached Grenadier Guards.

Capt. J. Green, R.A.M.C., attached Royal Field Artillery.

Capt. E. S. Johnson, R.A.M.C., attached Rifle Brigade.

Capt. W. B. Lawrence, R.A.M.C., attached Royal Field Artillery.

Capt. P. J. O'Reilly, R.A.M.C., attached Norfolk Regiment.

Lieut. R. F. Williams, R.A.M.C., attached Yorkshire Regiment.

Capt. J. Brown, New Zealand Medical Corps.

Capt. E. S. Jeffrey, Canadian Army Medical Corps.

Lieut. T. W. Sweetnam, R.A.M.C., attached Royal West Surrey Regiment.

Capt. J. F. Bourke, R.A.M.C., attached Cameronians.

Lieut. G. B. Ferguson, R.A.M.C.

Capt. K. G. Fraser, R.A.M.C.

Capt. H. E. P. Yorke, R.A.M.C., attached East Yorks Regt.

Capt. W. Ainslie, R.A.M.C.

Capt. T. E. B. Beatty, R.A.M.C., attached East Kent Regt.

Capt. J. S. Wallace, R.A.M.C.

Capt. W. B. Allen, R.A.M.C.

Capt. J. A. Pridham, R.A.M.C.

Capt. G. N. B. Sebastian, R.A.M.C., attached Royal Field Artillery.

Capt. P. R. Woodhouse, R.A.M.C., attached Irish Guards.

Missing.

Capt. A. T. Logan, R.A.M.C., attached Grenadier Guards.

AUXILIARY R.A.M.C. FUNDS.

The personnel of the Committee appointed to administer the Officers' Benevolent Branch of these funds has now been completed to the total of 20 by coöption and consists of: Lieutenant-Colonel H. G. Barling, Colonel Sir J. Rose Bradford, K.C.M.G., C.B., Lieutenant-Colonel W. Collier, Major A. C. Farquharson, Colonel Sir James Kingston Fowler, K.C.V.O., Lieutenant-Colonel H. P. Hawkins, Colonel Culver James, Major H. H. Littlejohn, Colonel D. J. Mackintosh, M.V.O., Major Ewen Maclean (chairman), Lieutenant-Colonel O. W. Mansell Moullin, Major D. W. Patterson, Major G. Newton Pitts, Lieutenant-Colonel W. Pasteur, Captain R. J. Stirling, Surgeon-Colonel Atwood Thorne, V.D., Colonel H. H. Tooth, C.M.G., Lieutenant-Colonel F. H. Westmacott, Lieutenant-Colonel W. Hale White, and Lieutenant-Colonel G. Sims Woodhead. The secretary is Lieutenant-Colonel F. W. H. Davie-Harris, at 124, Victoria-street, S.W.

OBITUARY OF THE WAR.

ROLAND PLAYFAIR CAMPBELL, B.A., M.D.,
C.M. MCGILL,

LIEUTENANT-COLONEL, CANADIAN ARMY MEDICAL CORPS.

The loss that has fallen upon the Canadian Army Medical Service by the death at the front of Lieutenant-Colonel R. P. Campbell is indeed heavy, so great was the respect he inspired from all who came in contact with him, so whole-hearted was the devotion of his colleagues and of his unit towards him, and so thorough, modest, and capable was he in all his duties, whether as a medical man or a soldier.

"Bly" Campbell, as all his friends termed him, was a son of the Manse, his father being a well-known Canadian Presbyterian, the late Rev. Professor John Campbell. Born in Montreal in July, 1876, he had a distinguished career as a student, graduating B.A. in 1897 and M.D., C.M. in 1901. Following graduation, he was for two years resident in the Montreal General Hospital, then for more than a year he continued his studies in Germany, becoming *interne* at the Pathological Institute at Göttingen, and working also at the Surgical Clinic at Breslau, where, under Neisser, he became specially interested in genito-urinary surgery, which he made his life work.

Returning to Montreal, he was appointed medical superintendent of his old hospital, holding this position for three years, until 1907. Later he was made assistant surgeon and given charge of the genito-urinary clinic of that hospital. From being demonstrator in pathology he became lecturer in genito-urinary surgery at McGill University. Keenly interested in research, he wrote several papers upon renal pathology and surgery. When Ehrlich, prior to placing salvarsan at the disposition of the profession in general, sent over a supply of this drug in advance to the leading syphilologists in North America, Campbell first received it in Canada and tested and reported upon it. He was, in fact, an admirable example of the research surgeon and had a profound influence in encouraging other young surgeons in Montreal, who seemed naturally to gather around him, to undertake research. He was thus largely influential in the establishment in the University of a Department of Experimental Medicine, open to practitioners in the city.

He had joined the Canadian Army Medical Corps in 1905, and in 1910 was placed in command of No. 5 Canadian Field Ambulance at Montreal. An enthusiastic soldier, he offered his services at the very beginning of the war, and from No. 1 Field Ambulance was attached as Major to No. 1 Canadian General Hospital, C.E.F. With this unit he was in charge of the Canadian sick through the winter of 1914-15 at Salisbury Plain, there accomplishing excellent work under very difficult conditions. In the meantime No. 6 Canadian Field Ambulance was being assembled at Montreal by Major Burnett. In March, 1915, he was called back to assume command of this unit as Lieutenant-Colonel.

It has been urged that so capable a specialist should have been employed by the Canadian Army Medical Service in direct connexion with his specialty; but Campbell was a soldier before everything, and preferred the command of his unit at the front to any administrative or special position that could be offered to him. Nor is it any exaggeration to say that his unit rapidly made a reputation for itself by its remarkable capacity and *esprit de corps*; even its "horse lines" were acknowledged to be the best along the whole front. In Sir Douglas Haig's despatch of June 15th he was mentioned for gallant and distinguished conduct in the field. During the three days' operations beginning on Sept. 15th he was placed in charge of the clearing of the ground in the front area; and, to quote the Assistant Director of Medical Services, Colonel Fotheringham, "Campbell, with his usual sense of duty and disregard of personal safety, was well up with the advance on the morning of Saturday, the 16th, . . . trying to estimate the situation for himself rather than depending on information from regimental medical officers and bearers." It was here, just after dawn, when conducting a group of bearers towards safety, that a shell exploded and a fragment fractured his right arm while another penetrated his chest. Borne back to a dug-out, he there refused to be treated, directing that others whose wounds were not hopeless should be looked after. And so he died within half an hour from internal hæmorrhage. He was a very perfect gentleman, and his manner of death was the epitome of his life.

FREDERICK WILLIAM THEODORE CLEMENS,
M.B., B.S. LOND.,
SURGEON, ROYAL NAVY.

Temporary Surgeon F. W. T. Clemens, who was among those killed in action on board H.M.S. *Defence* during the naval battle off the Skager Rak on May 31st, was 27 years

of age and only son of the Rev. T. L. Clemens, of Tobago, West Indies. His early education was obtained at the Moravian School at Fulneck, near Leeds. In 1905 he joined the Moravian Mission College in Bristol, hoping to become a medical missionary, but, to his great disappointment, was rejected on the ground of health. He continued to study at Bristol University, gaining the Clarke Surgical Scholarship and qualifying M.B., B.S. Lond. in 1913. He then took a position as house

surgeon at Taunton Hospital, which he resigned at the outbreak of war on obtaining a commission in the Royal Navy.

One of his Bristol teachers writes of Surgeon Clemens that he was a brilliant student, always a steady worker, and at the same time popular with his fellows. His ability included the power of original observation. He made many friends at Bristol, and in a quiet, unostentatious way exercised a constant influence for good on those around him.

Surgeon Clemens was an accomplished musician and keen on out-door sport. At one time he was in the running for the captaincy of his University boat.

HUGH KENNEDY BIRLEY, M.R.C.S., L.R.C.P. LOND.,
CAPTAIN, MANCHESTER REGIMENT.

Captain H. K. Birley, attached to the Manchester Regiment, who was killed in action on July 23rd in his forty-seventh year, was the eldest son of Frederick Hornby Birley, of Bedford, and late of Manchester. Educated at the Owens College, Manchester, he qualified as M.R.C.P. Lond., M.R.C.S. Eng. in 1895, and went into practice at Irlams-o'-th'-Height, Manchester, where his cheery and

unselfish disposition much endeared him to his patients. Prior to setting up in practice he was a keen member for ten years of the Manchester volunteers, and at the outbreak of war at once offered his services and obtained a captaincy in one of the battalions raised by the city of Manchester. He devoted to his new profession the same keenness and sense of duty which had characterised his work amongst his patients. After a winter and spring of life in the trenches, where his professional knowledge was many times of service to his comrades, he lost his life in the advance on the Somme.

Captain Birley was much beloved by his fellow officers and men. "Many a boy of ours," writes one of his company, "has left the trench badly wounded to go down to the dressing station with a smile on his face, and telling everyone he passed that he felt all right as Captain Birley had attended to him and dressed his wounds." Before the outbreak of war Captain Birley devoted much energy to Red Cross work

in Pendleton, where he held the position of assistant county director.

Captain Birley married in 1900 the third daughter of the late Canon Stowell, of Chorley, Lancashire.

DEATHS AMONG THE SONS OF MEDICAL MEN.

The following sons of medical men must be added to our lists of those who have fallen during the war:—

- Capt. C. B. Wilson, Canadian Infantry, only son of the late Dr. C. B. Wilson, of Florence, Italy.
 Capt. J. D. Eccles, M.C., eldest son of Major McA. Eccles, R.A.M.C., of Harley-street, London.
 Second Lieut. J. L. Goddard, Norfolk Regiment, third son of Major C. E. Goddard, R.A.M.C., of Wembley, Middlesex.
 Lieut. C. J. P. T. S. Baly, The Buffs, elder son of the late Dr. P. P. Baly, of Westward Ho!, Devonshire.
 Lieut.-Col. A. N. Walker, R.A.M.C., second son of the late Mr. G. E. Walker, F.R.C.S., of Liverpool.
 Capt. H. Mackay-Coghill, Highland Light Infantry, second son of the late Dr. J. D. Mackay-Coghill, of Shrewsbury.
 Second Lieut. D. W. Armitage, Royal Sussex Regiment, youngest son of Dr. J. A. Armitage, of Netherwood, Hastings.
 Capt. O. G. Parry-Jones, R.A.M.C., elder son of Dr. M. Parry-Jones, of Derby.
 Lieut. C. E. McDonnell, Middlesex Regiment, elder son of Fleet-Surgeon J. R. McDonnell, of Gloucester-road, London, N.W.
 Capt. G. P. Selby, R.A.M.C., eldest son of Dr. P. G. Selby, of Teynham, Kent.
 Major G. E. Kidd, Royal Field Artillery, eldest son of Dr. P. Kidd, of Brook-street, London, W.
 Capt. F. W. C. Hinings, East Yorkshire Regiment, younger son of Dr. J. W. Hinings, of Leeds.

THE WORK OF THE ARMY DOCTOR.

In the *Times* of Oct. 4th there is an excellent description from the pen of Lord Northcliffe of the life of the medical man under fire. The fine work done by the medical service of our Army has been recognised by all whose opinion is worth having, but few perhaps outside the Service itself, and those to whom it actually ministers, have realised how elaborate the organisation has necessarily been to give such good results, or how strenuous are the toil and moil which maintain the construction in its high state of efficiency. Lastly, the sacrifice that has been made by many doctors of their lucrative practices in order that they may give their services to the Army has not hitherto received its due public acknowledgment. All this is set right in Lord Northcliffe's vivid and instructive communication. Describing the scene in an underground trench hospital in the firing line, which is diagrammatically represented in the article, Lord Northcliffe says: "In all my experiences abroad I have never seen a more touching sight than this little underground gathering of some 70 men, devoted doctors and assistants, waiting amidst the incessant shelling until the overcrowded maze could be evacuated. Let those who take their ease on a Sunday afternoon, or any other afternoon, realise that this same scene never ceases. Let those who consider that they are amply doing their 'bit' by keeping things going at home be grateful that their 'bit' is not as these young men's. We cannot all of us share the danger, but we can every one of us admit the harsh inequalities of our respective war work."

THE NEED FOR MICROSCOPISTS.

The Young Men's Christian Association are organising a series of microscopical exhibitions in the military and naval camps for the interest of the men in their leisure hours. An organising committee, consisting of Fellows and members of the Royal Microscopical Society, Quekett Microscopical Club, and the Photomicrographic Society, has been formed, and already many fixtures have been made for exhibitions to be held in the Young Men's Christian Association huts in various centres throughout the metropolitan area and the home counties. The exhibitions generally take place in the late afternoons or evenings, and competent microscopists who can spare the time to give service with their microscopes are invited to communicate with the Honorary Secretary, Microscopical Department, Young Men's Christian Association, Tottenham Court-road, W.

Medical News.

UNIVERSITY OF GLASGOW.—The following results of examinations are announced:—

DEGREES OF M.B. AND CH.B.

Medical Jurisprudence and Public Health (Fourth Professional Examination—New Medical Ordinance).—William Adams, Robert Aitken, John Ashtorth, Alexander Basil Austin (distinction), John Salisbury Craig, William Dempster, Andrew Dick, Kenneth Henry Dyke, Samuel Norman Dykes, James Paton Fleming, Thomas Forrest, Walter Watson Forsyth, Lewis Livingstone Fotheringham, Robert John Leslie Fraser, Jacob Joels, William Hogarth Kerr, M.A.; William Mackintosh Kerr, George Lean, B.Sc.; James Liddell, Frederick Richard Lubbovis, Hugh Ernest McColl, Donald William Morison Mackenzie, Donald James Mackinnon, John Marshall, Jules Steinmetz Martin, M.A. (distinction), David Stephen Mitchell, James Moffat, James Walker Patterson, George Pearson, Samuel Murdoch Riddick, John Llewelyn Rowlands, Frank Watt Sandeman, James Hamilton Shearer, Clarence Lorraine Somerville, Douglas Taylor, James Joseph Treanor, William Halliday Wallace, John Pendleton White, Robert Wiggins, George Young, Jean Mary Frew, Grace Lelsk Hunter, Elizabeth Clark McHaffie, M.A., May Elizabeth MacIver, Robina Stuart Mackinnon, Jessie Brown MacLachlan, and Lillias MacLay.

Medical Jurisprudence and Public Health (Third Professional Examination—Old Medical Ordinance).—John Bradford, Peter Fife Auchinachie Grant, Robert Hugh McKillop, William Duff Miller, and Pat Adam Stewart.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—The opening meeting of this society will be held to-day (Friday, Oct. 6th), at 8.30 p.m., in the Society's Rooms, West London Hospital, when the presidential address on Some Aspects of the Nose and Throat in Relation to General Medicine will be delivered by Dr. Arthur Saunders.

Baron Heyking, the Imperial Russian Consul-General in London, will take the chair at a public lecture to be delivered by Professor W. M. Bayliss, F.R.S., on "The Physiological Work of Ivan Petrovitch Pavlov," at University College, London, to-day, Friday, Oct. 6th, at 5.30 p.m. The lecture will be open to the public without fee or ticket.

GUY'S HOSPITAL MEDICAL SCHOOL.—The following Entrance Scholarships have been awarded:—Senior Science Scholarships for University Students: William Gover, Balliol College (£75); and Robert Blake Poole Lansdown, B.A., Pembroke College, Cambridge (£35). Junior Science Scholarships: Alan McKenzie, Preliminary Science Class, Guy's Hospital (£120). Scholarships in Arts: Antoine Yves Cantin (private study) (£100); John Alexander Currie, Diocesan College, Rondebosch, Cape Colony (£50).

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index). When the application of a Belgian medical man would be considered the advertisers are requested to communicate with the Editor.

ASHTON-UNDER-LYNE DISTRICT INFIRMARY.—Junior House Surgeon. BARROW-IN-FURNESS, NORTH LONSDALE HOSPITAL.—Assistant House Surgeon.

BECLES, SUFFOLK, 1st CYCLIST BRIGADE FIELD AMBULANCE.—Three Medical Officers. Also Regimental Medical Officer for 2/1st West Somerset Yeomanry.

BEDFORD COUNTY HOSPITAL.—Assistant House Surgeon, unmarried. Salary £150 per annum, with board, &c.

BOLTON INFIRMARY AND DISPENSARY.—Female Second House Surgeon. Salary £200 per annum, with board, &c. Also Female Third House Surgeon. Salary £180 per annum, with board, &c.

BRISTOL ROYAL INFIRMARY.—House Physician. Salary at rate of £120 per annum, with board, &c.

CHISWICK URBAN DISTRICT COUNCIL.—Dental Surgeon.

DENBIGHSHIRE COUNTY COUNCIL.—Female Assistant Medical Officer of Health. Salary £350 per annum.

DORSET COUNTY COUNCIL EDUCATION COMMITTEE.—School Dentist. Salary £250 per annum.

SEXBY EDUCATION COMMITTEE.—Female School Medical Inspector. Salary at rate of £300 per annum.

HUDDESFIELD COUNTY BOROUGH EDUCATION AUTHORITY.—Assistant School Medical Officer. Salary £300 per annum.

HULL, CITY AND COUNTY OF, KINGSTON-UPON-HULL INFECTIOUS DISEASES HOSPITALS.—Resident Medical Officer. Salary £300 per annum, with board, &c.

ISLEWORTH UNION INFIRMARY.—Temporary Assistant. Salary £375 per annum with rations, &c.

ITALIAN HOSPITAL.—House Surgeon for six months. Salary £80 per annum, with board, &c.

LEEDS PUBLIC DISPENSARY.—Female Resident Medical Officer. Salary £200 per annum, with board, &c.

LIVERPOOL, DAVID LEWIS NORTHERN HOSPITAL.—House Surgeon for six months. Salary at rate of £150 per annum, with board, &c.

LONDON THROAT HOSPITAL, 204, Great Portland-street, W.—House Surgeon. Salary £50 per annum.

MACCLESFIELD, CHESHIRE COUNTY ASYLUM, Parkside.—Temporary Assistant Medical Officer. Salary £300 per annum, with board, &c.

MIDDLESEX HOSPITAL, W.—Vacancy on Honorary Staff.

MONMOUTHSHIRE COUNTY COUNCIL.—Female Assistant Medical Officer. Salary £350 per annum.
 NETLEY, WELSH HOSPITAL.—Medical Officers.
 NOTTINGHAM GENERAL HOSPITAL.—Two House Physicians and One Assistant House Surgeon for six months. Salary at rate of £250 per annum each, with board, &c.
 PADDINGTON GREEN CHILDREN'S HOSPITAL, W.—House Physician—House Surgeon for six months. Salary at rate of £30 per annum.
 PRESTON, LANCAS. COUNTY ASYLUM, Whittingham.—Local Tenens, unmarried. Salary £77s. per week, with board, &c.
 QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone.—Physician in Charge of Ante-Natal Department.
 ROYAL FREE HOSPITAL, Gray's Inn-road, W.C.—Two House Physicians and two House Surgeons. Salary £50 per annum, with board &c. Also Senior Obstetric Assistant. Salary £33 per annum, with board, &c. Also Junior Obstetric Assistant. Salary £23 per annum, with board, &c. Also Assistant Anaesthetist. Salary £23 per annum.
 SHEFFIELD, ROYAL INFIRMARY.—Two House Surgeons. Salary £100 per annum, with board, &c.
 SOUTHAMPTON, ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL.—House Physician. Salary £150 per annum, with board, &c.
 STAFFORDSHIRE EDUCATION COMMITTEE.—Two Permanent and Four Temporary Female Assistant School Medical Inspectors. Salary £300 per annum.
 SUNDERLAND ROYAL INFIRMARY, CHILDREN'S HOSPITAL.—Resident Medical Officer for six months. Salary £150 per annum, with board, &c.
 WANDSWORTH UNION INFIRMARY, Onseley-road, Balham, S.W.—Temporary Assistant Medical Officer. Salary at rate of 7 guineas a week, with board, &c.
 WARRINGTON INFIRMARY AND DISPENSARY.—Senior and Junior House Surgeons. Salary £200 and £150 per annum respectively, with board, &c.
 WEST BROMWICH AND DISTRICT HOSPITAL.—Assistant House Surgeon. Salary £120 per annum, with board, &c.

Births, Marriages, and Deaths.

BIRTHS.

FAWCUS.—On Sept. 25th, at Hartfield-road, Eastbourne, the wife of Lieutenant-Colonel H. B. Fawcus, C.M.G., R.A.M.C., of a daughter.
 GUSH.—On Sept. 16th, at Westville-road, Thames Ditton, the wife of Dr. Howard Gush, W.A.M.S., temporary Lieutenant, R.A.M.C., of a son.
 HEALD.—On Sept. 27th, at The Cottage, Weybridge, the wife of Captain C. B. Heald, R.A.M.C., of a daughter.
 NEWBERRY.—On Sept. 28th, at India-street, Edinburgh, to the wife of the late Lieutenant Richard Fenton Theodore Newberry, R.A.M.C., a son.
 SYKES.—On Sept. 28th, at Ashhurst, Formby, Lancs, the wife of Dr. A. Barry Sykes, of a son.

MARRIAGES.

ASHTON—MORHAM.—At 17, Mansion House-road, Edinburgh, on Sept. 23rd, by the Rev. James Lumsden, B.D., Minister of Tolbooth parish, Captain Basil Cedric Ashton, R.A.M.C., to Agnes May, youngest daughter of George Morham, Edinburgh.
 GORDON—PROCTER.—On Sept. 28th, at Cockerham Church, Lancashire, William Bonnalie Gordon, Captain, R.A.M.C., son of W. B. Gordon, of Bradford and Ilkley, to Joan, daughter of H. T. Procter, of New Fields, Bay Horse, Lancashire.
 RUSHBROOKE—BALDWIN.—On Sept. 29th, at Stoke Newington Presbyterian Church, Montague Penhall Rushbrooke, R.A.M.C., to Vera Louise Baldwin, only daughter of Arthur Baldwin, Solicitor, and Mrs. Baldwin, of "Fretville," Lordship Park, N., and "Inglewood," Herne Bay, Kent.
 SOWDEN—HEYWOOD.—On Sept. 29th, at Christ Church, Albany-street, N.W., George Sowden, M.D., P.P.H. Camb., Barrister-at-Law, to Doris Burnett, youngest daughter of the late Henry Cleland Heywood.
 STIDSTON—CUMBERLAND.—On Sept. 27th, at the Parish Church, Luton, by the Rev. J. St. Clare Hill, Lieutenant-Colonel C. A. Stidston, M.D., R.A.M.C., T.F., of Wolverhampton, and Olive, youngest daughter of Mr. Hugh Cumberland, J.P., of The Lynchet, Luton, and the late Mrs. Jeanie Cumberland.
 WILLIAMS—THOMAS.—On Sept. 28th, at the Welsh Presbyterian Church, Charing Cross-road, London, Major O. Herbert Williams, R.A.M.C., to Ethel Kendrick Thomas, daughter of the late William Thomas and Mrs. Thomas, Alburgh-drive, Liverpool.

DEATHS.

BENSON.—On active service, on Sept. 24th, Major Alfred Hugh Benson, R.A.M.C., Officer Commanding Mounted Brigade Field Ambulance.
 BOGLE.—Killed while attending the wounded, on Sept. 17th, Gilbert Vere Bogle, M.B. Edin., Captain, N.Z.M.C., of Hawkes Bay, New Zealand, aged 32 years.
 DEIGHTON.—Died of wounds, on Sept. 19th, Captain John Deighton, M.B., R.A.M.C., Medical Officer to King's Own Royal Lancaster Regiment.
 GILBERT-SMITH.—On Sept. 27th, at Tenby, Edwin Gilbert-Smith, F.R.C.S.E., of Calthorpe-road, Edgbaston, and Newhall-street, Birmingham.
 KEMBLE.—Died at sea, buried at Penang, on July 31st, Arthur Charles Kemble, L.R.C.P., L.R.C.S. Ed., aged 62 years.
 SELBY.—Killed on Sept. 28th, while attending the wounded, Gerard Prideaux Selby, B.A., M.B., B.Ch. Oxon., M.R.C.S., L.H.C.P., Captain, R.A.M.C., aged 25 years.
 WALKER.—Killed in action, on Sept. 24th, Arthur Nimmo Walker, Lieutenant-Colonel, R.A.M.C.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

ANNUAL REFERENCE BOOKS.

IN spite of shortage of paper, difficulty in obtaining labour, and other inconveniences engendered by the war, annual reference books appear fairly regularly, while the accuracy of their contents speaks well for the pains that have been bestowed upon their compilation. That most useful work, *The Charities Register and Digest* (London: Longmans, Green, and Co. Pp. cccxxxiv. + 686. Price 5s. net), is now in its twenty-fifth edition, and besides containing a classified register of charities in or available for the metropolis, gives a large amount of information respecting legal and voluntary means for the prevention and relief of distress and the improvement of the condition of the poor, while there is a useful introduction on how to help cases of distress, written by the compiler, Mr. C. S. Loch, late secretary of the council of the Charity Organisation Society. For conciseness, convenience of reference, and cheapness, the oldest guide to the charities of London, *Low's Handbook* (London: Sampson Low, Marston, and Co., Ltd. Pp. 254. Price 1s. net), easily takes a first place. All the charities are arranged alphabetically, a paragraph of a few lines giving exactly the kind of information which a prospective donor, or a person seeking information for a suitable case, is likely to require. The book is now in its eighty-first year of publication. An illustrated preface tells the story of King's College Hospital, past and present. *The Girls' School Year-Book* (Public Schools) (London: The Year Book Press. Pp. 654. Price 5s. net) is issued as the official year-book of reference of the Association of Head Mistresses, but it also provides a record of all matters of interest to parents, schoolmistresses, and girls in connexion with secondary education. Nearly half of the book deals with the future career of girls on leaving school, and particulars are given of various professions and openings for girls. *British Rainfall, 1915*, compiled by Dr. H. R. Mill (London: Edward Stanford, Limited. Pages 283. Price 10s.), we also include in this list, because it is essentially a book of reference. It contains an epitome of the year's meteorological work, it is well illustrated with maps and diagrams, and there are articles upon various branches of rainfall work. The records have been made by about 5,500 observers.

HEALTH OF GAMBIA.

ACCORDING to a report on the Blue-book of Gambia for the year 1915, prepared by Mr. W. Telfer Campbell, Colonial Secretary, the total population of the Colony and Protectorate is a little over 146,000, including 123 Europeans, of whom 44 are officials. No death or case of invaliding occurred amongst the European residents during the year. The death-rate in the Colony showed a decrease, being 35.4 per mille, as against 39.8 in 1914. The Colony was free from any epidemic, but in parts of the Protectorate small-pox was prevalent. In the Bathurst Hospital 483 in-patients and 8304 out-patients were treated, as compared with 566 and 9799 respectively in 1914. There is a smaller hospital at MacCarthy Island under a native dispenser; it contains one ward for Europeans and three for native patients. A building situated about two miles from Bathurst is used for contagious diseases. In 1915 there were 660 vaccinations performed in Bathurst and 2057 in the Protectorate. The rainfall for the year was 47.64 inches. The highest shade temperature recorded was 100° and the lowest 52° F.

SENILE DIARRHOEA.

To the Editor of THE LANCET.

SIR,—With such causes of diarrhoea as cancer of the stomach and intestines, tuberculosis, ulcerative colitis out of the reckoning, catarrh of the large bowel with painless diarrhoea may occur in many circulatory disturbances, and "M.D. (R.N.)," whose letter appears in your issue of Sept. 30th, might get a clue by (if not already done) taking the blood pressure, as such catarrh accompanied by very persistent diarrhoea is not infrequently found in late cases of chronic Bright's, especially chronic interstitial. By no means is it necessary that either albumin or casts be present.

I remember some years ago in my private practice a case in point. After consultation I discussed the case with Sir Lauder Brunton, and in the absence of any history of Bright's disease we decided to tell the relatives the difficulties in making a positive diagnosis. We suggested as the most likely cause of the diarrhoea (which had trickled away without cessation for over two weeks continually) malignant disease, if not chronic Bright's disease. After death the relatives (alarmed at the idea of cancer) expressed a wish for a post-mortem. The whole length of the bowel showed no

pathological condition, but the kidneys were both a mere flattened-out, pancake-like mass, nearly all fibrous tissue, although frequent examinations during life had failed to discover albumin or casts.

From somewhat similar cases I have had I have found treatment on the lines indicated in cases of chronic Bright's and high blood pressure, when present, the most useful. Hot baths, electric-light baths, ionisation in Schnee's baths, lithium or sodium hippurates, and to arrest the diarrhoea strictly liquid food, with, say, milk once or twice or more a day, given cold, with one or more tablespoonfuls of raw arrow-root stirred up with it and taken uncoked. Medicines are not much use, except, perhaps, alkalies with liq. bismuth. et ammon. citratis.—I am, Sir, yours faithfully,

Bournemouth, Oct. 2nd, 1916.

G. H. RUTTER.

THE EVENING STOOL.

To the Editor of THE LANCET.

SIR,—Some years ago I ventured to call the attention of the profession to the mischief wrought by a certain tradition of the elders, but as I suppose I did not write as one having authority, apparently my hint has been ignored, or even despised, for I constantly find that if I mention the point thoughtful men are favourably impressed with the idea, but only once have I found anyone who seemed to have heard of it before.

It is the rule that doctors advise their patients to form the habit of evacuating immediately after breakfast. By all means let them do this so long as they regard the practice merely as an "extra luxury" and as an inexorable rule that they must stool between dinner and bed-time. A moment's thought and the reasons for this "leap to the eye." Firstly, the morning rule is constantly broken, and must be broken by busy people who have trains to catch. They say to themselves, "Must wait till I get to the office"; but business crowds it out, and so they go through the day poisoning themselves (I use the unnecessarily strong word for brevity), until chronic constipation and all its hideous consequences may be established. Secondly, during sleep, and while vitality is at its lowest, the body is more vulnerable to attack and less resistant to fecal poisons, which during eight hours it steadily absorbs. For these reasons I would urge the profession to forbid their patients to go to bed with a full rectum.

I am, Sir, yours faithfully, and write from

Sept. 29th, 1916.

PERSONAL EXPERIENCE.

PEMMICAN.

To the Editor of THE LANCET.

SIR,—The etymology of the word "pemmican" given in THE LANCET of Sept. 9th is not very full. I enclose an abstract from Father A. Lacombe's Cree-French Dictionary which has reached me from Winnipeg. I am informed that the "e" in the word should be "i."

I am, Sir, yours faithfully,

Oct. 2nd, 1916.

W. E. B.

ENCLOSURE.

Pemmican—"pimty" (noun), grease, fat; "pimtiw," greasy; "pimtkew," the act of making grease; "pimtkewin," the act of making pemmican, grease, &c.; "pimtkkan," a bag filled with a mixture of grease and pounded meat, is pemmican. From Skeat's "Etymological Dictionary of the English Language." "Pemmican," a preparation of dried meat (N. American Indian); a Cree word; see Cree Dictionary by Lacombe.—Cree "pimtkkan," pemmican, a bag filled with a mixture of fat and meat, from "pimty"—grease.

NEOCAINE-SURRENINE.

Messrs. The Anglo-French Drug Co., Ltd., of Gamage-buildings, Holborn, London, E.C., referring to our analytical notice last week of neocaine-surrenine, point out that the actual time taken to induce anaesthesia, employing this substance, is exactly that taken by cocaine of equal strength.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simon: Diseases of Women.

TUESDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Dr. Simon: Diseases of Women.

THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Simon: Gynecological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics.—10.30 A.M., Surgical Out-patients (Mr. B. Gillespie). 2.30 P.M., Medical Out-patients (Dr. T. E. Whipple); Gynecological Out-patients (Dr. Banister). 3 P.M., Medical In-patients (Dr. R. M. Leslie).

TUESDAY.—2.30 P.M., Surgical Operations (Mr. Carson). Clinics.—Medical Out-patients (Dr. A. G. Auld); Surgical Out-patients (Mr. Howell Evans); Nose, Throat, and Ear Out-patients (Mr. C. H. Hayton). Radiography (Dr. Metcalfe). 3.30 P.M., Medical In-patients (Dr. A. J. Whitting).

WEDNESDAY.—Clinics.—2.30 P.M., Throat Operations (Mr. C. H. Hayton). Children Out-patients (Dr. T. E. Whipple); Eye Out-patients (Mr. R. P. Brooks); Skin Out-patients (Dr. H. W. Barber). 5.30 P.M., Eye Operations (Mr. R. P. Brooks).

THURSDAY.—2.30 P.M., Gynecological Operations (Dr. A. E. Giles). Clinics.—Medical Out-patients (Dr. A. J. Whitting); Surgical Out-patients (Mr. Carson); Radiography (Dr. Metcalfe). 3 P.M., Medical In-patients (Dr. R. M. Leslie).

FRIDAY.—2.30 P.M., Surgical Operations (Mr. Howell Evans). Clinics.—Medical Out-patients (Dr. A. G. Auld); Surgical Out-patients (Mr. B. Gillespie); Eye Out-patients (Mr. R. P. Brooks).

THE THROAT HOSPITAL, Golden-square, W.

MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.

THURSDAY.—5.15 P.M., Clinical Lecture.

ST JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C.

THURSDAY.—6 P.M., Chesterfield Lecture:—Dr. M. Dockrell: The Skin in Health and Disease.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

Offices: 423, STRAND, LONDON, W.C.

MANAGER'S NOTICES.

ALTERATION OF INLAND SUBSCRIPTION RATES.

OWING to the alteration in the Inland Newspaper Postal rate, the postage on each copy of THE LANCET will in future be 1d., and sometimes 1½d.

The revised Inland Subscription rates are:—

| | |
|---------------------|--------|
| One Year | £1 3 3 |
| Six Months | 0 13 8 |
| Three Months | 0 7 0 |

The rates for the Colonies and Abroad (thin paper edition) will be as usual:—

| | |
|---------------------|--------|
| One Year | £1 5 0 |
| Six Months | 0 14 0 |
| Three Months | 0 7 0 |

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed

"London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET OFFICES, 423, Strand, London, W.C.

ADVERTISEMENT RATES.

An Address

JOHN WARD AND HIS DIARY.

Delivered at the Medical Society of London on the Occasion of His Induction as President, Oct. 9th, 1916,

By D'ARCY POWER, F.R.C.S. ENG.,

SURGEON AND LECTURER IN SURGERY, ST. BARTHOLOMEW'S HOSPITAL;
LIEUTENANT-COLONEL, R.A.M.C. (T.F.).

PART I.

GENTLEMEN,—I cannot begin this address without expressing my sense of the great honour you have conferred upon me by placing me in this chair. My unworthiness to fill it is borne in upon me with especial force when I look round and see on the walls of this room the names of my 96 predecessors, all eminent in their profession, many illustrious also for their civic and moral virtues. The tradition of the society is a great one, and will prove hard to maintain in the third year of a war which has dislocated every relationship in life. I can count, however, upon the loyal support of my secretaries and the other officers of the society, and with their help I hope to hand it on unbroken to my successor.

It is usual for the President to give an address at the beginning of his year of office upon a subject which is of interest to the society. To some the selection of a topic must have been difficult. I am fortunate in having one ready to hand, because three or four years ago the Council gave me permission to transcribe the manuscript volumes known to us as "John Ward's Diaries." They have long been amongst the most treasured possessions in our library, and, as the event proved, they have never been adequately examined. It is not known how they came into our possession, but in all probability they formed part of the collection of books belonging to Dr. James Sims, who was President from 1786-1809. This long tenure of office caused the schism which led to the foundation of the Royal Medical and Chirurgical Society, which now flourishes as the Royal Society of Medicine.

The note-books are 16 in number, roughly uniform in size, measuring $5\frac{1}{2} \times 3\frac{1}{2}$ inches, and have been whole-bound in calf. One volume has "J. W." stamped in gold, back and front—the precursor of a book-plate. The volumes vary in thickness. The writing is on both sides of the page, sometimes only a word or two, sometimes with blank pages, but for the most part so much crowded that a reading-glass is necessary to decipher it. The volumes follow a sequence of years from 1647-48 until 1673, but the order of date is not followed strictly year by year, though it looks as if a new volume was not usually begun before the previous one was filled. The books are in no sense diaries or records of events from day to day like the diaries of John Evelyn or Samuel Pepys. They are rather of the nature of "table books," or "common-place" books, in which Ward recorded from time to time notes of what he had read or heard, or ideas and suggestions which might prove serviceable. Although there is nothing of great historical interest, yet the general view gained from reading them affords an insight into the character of Ward which is valuable as giving the opinions and occupations of a scholar and a gentleman during the Commonwealth and Restoration periods.

DR. SEVERN'S BOOK ON THE DIARIES.

An investigation of the minutes of this society shows that on Oct. 5th, 1838, "a letter was read from Dr. Severn announcing that the MSS. of Dr. John Ward, of Stratford, in the society's library, contained curious matter relating to Shakespeare, &c. It was resolved that a committee should be appointed to investigate the subject and report thereupon to the Council at their earliest convenience. The following gentlemen were nominated on the committee: Messrs. Clifton, Dendy, Headland, Kingdon, and Roberts." On Nov. 23rd, 1838, the committee appointed to examine Dr. John Ward's MSS. reported that "although they had found much that was amusing, interesting, and instructive among them, yet they were of too desultory a nature: the historical, medical, and clinical notices too much mingled together for the Society to offer them in their present state No. 4859.

to the public, but that, Dr. Severn having made extracts from them, the Society might give him permission to publish them, he acknowledging that it was done with the Society's sanction." The committee also recommended that the other manuscripts in the society's possession be catalogued. It was further resolved that permission be given to Dr. Severn to publish extracts from the MSS. of the Rev. John Ward.

Dr. Severn lost no time in availing himself of the permission, and early in the year 1839 there appeared an octavo volume of 315 pages with the title-page, "Diary of the Rev. John Ward, A.M., Vicar of Stratford-upon-Avon, extending from 1648 to 1679. From the Original MSS. preserved in the Library of the Medical Society of London. Arranged by Charles Severn, M.D., Member of the Royal College of Physicians in London, Registrar to the Medical Society of London. Published by permission of the Council. London: Henry Colburn, Publisher, Great Marlborough-street. 1839." This volume consists of a dedication to the President and other officers of the Medical Society; of a preface; of some account of the life of the Rev. J. Ward, A.M., and of a series of short articles upon Shakespeare, which together occupy the first 87 pages. The remaining 228 pages deal with the diary itself. It is clear that Dr. Severn had only made a superficial examination, but we owe him a debt of gratitude, not only for calling attention to the volumes, but also for the assiduity with which he gathered such biographical details of Ward as were then available.

Of Severn himself I have only been able to collect the following facts. He was admitted a Licentiate of the Society of Apothecaries on May 16th, 1816, and was found qualified to practise in any part of England and Wales, including the City of London and ten miles round. He lived for a time in Jewin-street, E.C., and from there published "First Lines in the Practice of Midwifery, to which are added remarks on the forensic evidence requisite in cases of feticide and infanticide. 8vo. Lond., S. Highley, 1839." He was admitted an extra licentiate of the Royal College of Physicians of London on Oct. 1st, 1832, and he had then obtained the degree of M.D., but from what university is now unknown. It was not from Oxford, Cambridge, or Glasgow. In 1839 he edited "The Lectures on the Principles and Practice of Midwifery by James Blundell," 12mo, J. Masters. This little book he dates from the society's house in Bolt-court, Fleet-street. He died in the summer of 1840, apparently leaving a wife and daughter.

The society's minute records on Sept. 4th, 1840, that "Mr. Dendy reported to the committee the decease of Dr. Charles Severn, the late Registrar." A vote of condolence was passed, and in accordance with the appreciation of his services, and, moreover, regarding the advanced age and debility of Mrs. Severn, the Council requests the family to remain in the society's house in order that they may take charge of its property and fulfil the directions of its librarians and secretaries until arrangements may be made regarding the office. Miss Severn performed the duties of Registrar until Sept. 5th, 1850, when Mr. Ley was appointed sub-librarian. On Nov. 9th, 1850, Mr. Dendy called attention to the claims of Miss Severn, and proposed that "on her leaving the premises in Bolt Court she be paid a year's salary to March next." This was seconded by Dr. Greenhalgh and agreed to. Miss Severn received £21 in March, 1851, the year in which the society migrated from Bolt-court to George-street, Hanover-square.

ASCERTAINABLE FACTS ABOUT JOHN WARD.

Before I give any extracts from the manuscript volumes which lie before you, it may be interesting to gather such facts about the writer as are still available. He was born at Spratton in Northamptonshire in the year 1629, the elder of the two sons of John Ward, M.A. of Pembroke College, Oxford, by Dorothy, a daughter of Richard Parfeter. John Ward the father was a gentleman of property,¹ who became a lieutenant in Colonel Appleyard's regiment of foot at the outbreak of the Civil War, was taken prisoner by the Parliamentary forces at Naseby in 1645, and probably died soon afterwards, for John Ward the younger makes no mention of his father, though his mother was living some

¹ His father, Daniel Ward (d. 1627), bought the estate and manor of Houghton Parva from Lord Zouche at the beginning of the reign of King Charles I., and he also held lands at Stoke Albany and Wilbarston, which he had purchased from Lord Danvers.

years later. The younger son, Thomas, became rector of Stow-on-the-Wold.

John Ward, the writer of the note-books, went to Oxford in the middle of "the broken times," as they were called by Anthony Wood, when the University and College lists were badly kept. It is not surprising, therefore, that his name does not appear in the registers. He states, however, that "I was presented Mr. of Arts about the year 1652 in Easter term. Anthony Ratcliffe and Philip Gerard and Mr. Temple with us."

Anthony Ratcliffe, of Magdalene College, Cambridge, matriculated 1st October, 1645, was incorporated 16th March, 1648-49, student of Christ Church by the visitors; B.A. 23rd May, 1649; M.A. 6th May, 1652; canon 11th February, 1680-81; chaplain to Henry Earl of Arlington; vicar of Leigh, Kent, 1661; died June, 1703.

Philip Gerard, son of William of London, gent., Christ Church, matriculated 29th January, 1646-47, aged 13, from Westminster School; B.A. 8th July, 1649; M.A. 6th May, 1652.

"Mr. Temple" was John, of Pembroke Hall, Cambridge. Admitted 30th January, 1645-46; student of Christ Church, 1648, by the visitors; B.A. 8th July, 1649; M.A. 6th May, 1652; vicar of Haughton 1660, and of Portslade, Sussex, 1669.

Ward also speaks of "our table at Christ Church"—i.e., the Master of Arts table in Hall where the resident Masters dined together. It is fair to assume, therefore, that Ward matriculated at Christ Church at the end of 1646 or the beginning of 1647, graduated B.A. in July, 1649, and took his degree of M.A. on May 6th, 1652. It is an interesting sign of the times that two of his friends had been incorporated from Cambridge, because such migrations at this time were usually due to political causes. It appears from various notes scattered through the books that he remained in residence at Oxford until the Restoration, when the whole social atmosphere of the University underwent such a change as to make it uncongenial to those who had lived in it through the period of the Commonwealth. During this time his interests lay in history and in science—chiefly chemistry, botany, medicine—and in general literature. He never took the degree of Bachelor of Physic, but it is probable that he held the status of student of medicine, a status then recognised in the University and only abolished within my own recollection. At any rate, he treated many sick persons by medicine, though it does not appear that he performed any operations.

He left Oxford in 1660, perhaps as a direct result of the Restoration, for, although his father suffered in the Royalist cause, his personal friends must have been of the modified Republican type, who were in residence during the Commonwealth. Casting about for a profession, it is clear that he was sorely tried to decide between the Church and physic. He took orders in 1660, and his note-books for this year contain numerous divinity notes and sermons. In 1661 he was in London attending lectures on anatomy at the Barber Surgeons' Hall in Monkwell-street, and debating in his own mind whether he should obtain a bishop's licence to practise medicine or an M.D. from a foreign university. He also interviewed "Mr. Giles, of Lincoln's Inn, who deals in spiritual livings." He thought first of Brentford, then of Kingston-on-Thames, where his friend, Dr. Bate, the Puritan doctor, is buried, and finally got himself instituted in 1662 to the vicarage of Stratford-on-Avon in succession to Alexander Beane, who had held the living since 1648. Beane was ejected at the Restoration, but his congregation built him a church in the town, and the Congregational Church in Rother-street is still known as the "Church of the Ejectionment." The presentation to the living was in the hands of the King, but before 1681, when Josiah Simcox, A.M., became vicar, it had passed into the hands of Charles, Earl of Dorset and Middlesex.

Ward held the living until his death on Sept. 12th, 1681. He was buried in the chancel near the north wall, and the following inscription was placed on a flat stone: "Hic jacet Joh. Ward, A.M., Sprattoniæ, Northampt., natus, hujus Ecclesiæ Vicarius per annos XIX. denatus fuit XII. die Septembris, Anno Domini MDCLXXXI., ætatis sue LII." The stone disappeared when the church was repaved in 1840, but the inscription was copied and the place of burial was recorded by the Rev. James Davenport, who was vicar from 1787-1842. I have little doubt that he was ruptured and that he died of phthisis. Of his domestic relations nothing is known, but as his will makes no mention of wife or child, it is probable that he never married.

THE REVIVAL OF SCIENCE IN WARD'S TIME.

A valuable feature of Ward's note-books is the insight which they give into the mental pursuits of the Oxford graduates during one of the most stimulating periods of the University's long career, an insight which is the more valuable because little is known of it except through the crabbed Life of Antony Wood. The note-books give an unvarnished and wholly personal account of the things which were uppermost in the minds of those who "sate at our table in Christ Church" by one who entered heart and soul not only into the new-born scientific spirit of the time but into the literary and social life. The books he read, the stories he heard, and the practice he saw, are all faithfully recorded. He shows himself throughout as a well-read gentleman, as insatiably curious as "the elephant's child," quite clear and decided in his opinions, which are founded on observed facts and not on theories, and yet curiously credulous to our eyes, for as yet science was in its infancy, there was no chemistry, no pathology, and medicine was still mediæval in character.

The stern realities of the Civil War, the military occupation of the city, the dispossession of the Royalist Fellows, and the introduction of Independents had finally displaced the authority of the schoolmen and put aside theological controversy. The undergraduates and the younger Bachelors and Masters were more interested in facts gained by observation and experiment than in the disputations and rhetorical displays which had pleased their fathers. Oxford was at the beginning of one of the great periods of awakened interest in natural science such as had occurred in the twelfth century during the lifetime of Roger Bacon and during the last quarter of the nineteenth century within our own memory. With the authors of this revival Ward was contemporary, and with many of them he was on terms of friendship.

The seventeenth-century revival of science led to the foundation in 1645 of the Philosophical College, which held its meetings at the lodgings of Dr. Jonathan Goddard in Wood-street, Cheapside. This was followed by the "Invisible College," or "learned Junto," which met at Wadham College when Dr. Wilkins was Warden and Dr. Goddard had succeeded William Harvey as Warden of Merton. The Invisible College contained the germ of the Royal Society, of whose foundation Ward says:—

I have heard this guesst abt as ye ground of founding ye Royal Societie. The King well knew yt Harrington who wrote Oceana and such strange fellows as have had their discourses and meetings and have talked of a Commonwealth; whereupon he instituted another societie, whereof his Royal Self vouchsafed to bee one, in opposition to itt, not thinking fitt to put down ye other by open contradiction.

The leaders of the scientific revival were nearly all Oxford graduates, though some of the most illustrious, like Wallis and Scarburgh, were only sons by adoption, for they had been incorporated from Cambridge. Most of the founders of the Royal Society were in residence with John Ward, who was born, as you will remember, in 1629, entered Christ Church in 1646 or 1647, and took his M.A. degree in 1652. Dr. Bathurst, of Trinity College, with whom Harvey spent many hours observing the changes in incubated hens' eggs, was nine years older than Ward. Dr. Willis, born in 1621, was eight years older. He entered Christ Church in 1636-37 and practiced in a house just opposite Merton. Robert Boyle, the greatest dilettante of the set, was born in 1626, and was living in Oxford at the house of Mr. Crosse, the apothecary in the High-street adjoining University College, in 1654. Richard Lower, born in 1631, entered Christ Church with a scholarship from Westminster in 1649. Christopher Wren, born in 1632, matriculated from Wadham in 1649-50 after he had acted for a time as prosecutor to Dr. Charles Scarburgh. Dr. Wallis, Glisson's first pupil and the friend of Samuel Pepys, came into residence at Exeter College as Savilian professor of mathematics in 1649.

This list of names, incomplete as it is, shows how inspiring must have been the atmosphere to a youth like John Ward, who had a strong inclination towards medicine and science, though he eventually entered the Church. While he was at Oxford Wilkins was considering the problem of perpetual motion; Harvey and Bathurst the development of the chick; Wallis the circulation of the blood; Willis and Lower anatomy in relation to the brain and heart; Barlow

of the Bodleian, oriental languages; Bobart, botany, and especially the movements of the sensitive plant. Ward notes of him: "Bobart ye physick gardiner has had a feavour in 1660 and after itt his hands and his feet peeled, his very flesh came off." All were interested in chemistry, which was as yet little more than alchemy, whilst physiology had hardly made any headway, for Mayow (1643-78), the gifted Cornishman whose early death was so great a loss, had not yet come to Oxford; Boyle was advancing physics; Goddard was doing something to make medicine scientific, but pathology was non-existent and physic was little more than folk-medicine.

EXTRACTS FROM THE NOTE-BOOKS.

The first volume of the commonplace books begins, "John Ward his booke, 1648 An. Dom. Aug. 26," about a year and a half after he had entered the University, and when he was 19 years of age. It contains an abstract of Sir Philip Sidney's "Arcadia," interspersed with extracts from Sir Thomas Browne's "Religio Medici." Perhaps some indication of his politics at this time is given in the statement that "Parliaments are good physic but ill meat." He next read "Tite Andronico," a novel full of sentiment if it may be judged by the sentences he selects that "shee was grown sick of a surfeit of health," and "poured soe full and fast compliments upon him that stifled therewith he could make no answer in return but stood in a swoond of amazement." And in another place: "The teares trickled down his reverend cheeks as if they had run a race which of them should be foremost," whilst "he went out as a Lamp for lack of oil, no warning groan was sighed forth to take his last farewell, but hee smiled himself into a Corps."

Having finished this novel he started on Sir Walter Raleigh's "History of the World," but the extracts are not numerous, and he very soon gave it up for "The Unfortunate Politick," a story of Herod and Mariamne, which was of the same sickly sentimental type as the other romances. He quotes as a part of it, "Seeing him now at the brink of the grave he flings himself in, expelling by brutish violence that soul which he was ready to surrender up to nature."

LECTURES IN MEDICINE: THE PULSE; PURGATIVES.

The book being finished, he returns to history, more especially the History of the Persian Wars, and a few pages later on there are notes of a lecture in Latin on medicine, the subjects being pleurisy, the urine, and menstruation. Other lecture notes deal with the pulse and with the uses and actions of purgatives. Harvey had not yet come to Oxford, and the Regius Professor of Physic does not appear to have accepted his views. He stated boldly that:—

A pulsibus diagnoscentur statūs vitales. In pulsibus, prout in corde, duo sunt motūs contrarii scilicet systole et diastole. [The vital conditions are diagnosed from the pulses. There are two contrary movements in the pulses as in the heart, namely, systole and diastole.]

The teaching in regard to purgatives took the following form in Ward's notes:—

The causes of purging medicines: (1) Extreme bitter as in Aloes and Colloquinta [Colocynth]; (2) Loathsome and horrible taste as Agarick and black hellebore; (3) by secret malignity many times not appearing in the taste as Scammony and Antimony; and if anything purge which hath not one of these 2 former virtues in it, it is to be suspected for poison.

The lecturer then proceeded to say that quantity was an element in the purging capacity, for

if we drink a great quantity of new milk it purgeth; that a mordication or vellitation of the orifice of the veins especially of the Mesentery veins: that almost all purges cause a kind of twitching and if it be in a high degree it is little better than poison which works by corrosion. The seventh cause of purging is attraction, for purging medicines have in them a direct force of attraction as drawing plaisters have in surgery. So Betony bruised and put into the nose draweth phlegm and water from the head. Those medicines that draw quick draw the fluid humors, those that draw slow work upon the viscous humours. Flatuosity is another cause of purging for wind stirred moveth to expell. Most purges lose their virtue by decoction upon the fire and for that cause they are chiefly infusion, juice or powder.

I have given the headings of this lecture as they stand, because it is evidence of the state of medicine in the University before the revival of science at Oxford.

WARD BECOMES M.A.: NATURE OF HIS STUDIES.

The second volume begins on May 27th, 1652, and opens with the exercise for the M.A. degree. The thesis was "An æstate an hieme plura sunt oblectamenta. Affirmatur quod æstate" [Whether the delights of summer or winter are the more numerous. It is decided in favour of summer]. The exercise would have taken about ten minutes to read. It ends sententiously with "Dixi," I have spoken. It is interesting as an example of the Austin disputation which preceded admission to the degree of M.A. Such a disputation or exercise was performed by every Bachelor of Arts once a year unless he had obtained a dispensation. It was held on any Saturday in term time between the hours of 1 and 3 o'clock in the choir of St. Mary's (the University Church) and was presided over by the masters of the school who received either a drachma (4d.?) or a pair of gloves as a fee. Three days' notice was given by affixing the subject of the disputation and the names of the disputants to the doors of St. Mary's Church.

The note-books give no further indication that Ward continued to read romances. They are filled with notes on more serious subjects as soon as he had taken his M.A. degree. After several pages devoted to divinity, to civil and to ecclesiastical law, he returns to natural science as it represented itself to him in alchemical speculations on antimony and mercury. There was still considerable belief in astrology. The philosopher's stone and aurum potabile were still the subjects of serious experimental work and led to the foundation of modern chemistry. The extracts on alchemy are "Ex Angelo Salâ." His botany he learnt from Bobart, the keeper of the Physic Garden in Oxford, by the delightful practice of "simpling," which meant pleasant summer days spent in walking to Shotover and Forest Hill, or afternoons in the Physic Garden itself. Anatomy he studied in "Briggs, his Anatomia"; physic in Ramondæus translated by Tomlinson; surgery in Paræus rendered into English by Johnson. Incidentally he mentions a case of hysterectomy. "Dr. Witherburne in London took out ye womb of a woman." Measles was raging at the time, for he records that the physicians say "the disease is autogenous like the plague; that the fever is less when the rash is coming out than afterwards, and that the backache before the appearance of the rash in measles is due to an excess of blood in the vena cava."

BOTANY.

Of Bobart, or Jacob as he always calls him, Ward has many reminiscences, chiefly during the year 1661. There were two Jacob Bobarts, father and son, both Horti Botanici Custodes. Ward must have known both intimately, but it is Jacob Bobart the elder [1599-1680] who taught him botany. He was born at Brunswick and was appointed superintendent of the Oxford Physic Garden on its foundation by the Earl of Danby in 1632. In 1648 he published a catalogue of 1600 plants under his care, and this was revised in 1658 in conjunction with his son. The revision, no doubt, was itself being revised when Ward knew him, and it explains his references to Gerard and Tomlinson. Ward's references enlarge our knowledge of the man who must have been one of those characters for which each generation at Oxford has been celebrated. We are told that "on rejoicing days he used to have his beard tagged with silver" and that a goat followed him instead of a dog. One of the earliest entries is:—

"Five sorts of fritillaries Jacob saies they have in ye Garden. Wee saw ym in flour March ye 23 1661 in ye Garden." "The 28 March 1661 wee went to Shotover to find Lunaria by Jacob's directions but found none." "I was upon New College wall on ye 17 April 1661 to find Ruta muraria but could find none; but much diastrium nigrum was there." "A great piece of horse chestnut. Remember yt I get a cup made of itt." "Jacob found a chestnut tree wild near Newburie and many hee hath seen growing in Sion College garden wch brought chestnuts to perfection." "Rochet seed scarce to be got. Jacob saies hee had itt not, nor scarce ever saw itt." "Jacob hath a very proper orchis wch resembles a Bee wch I saw May ye 4 1661." "That Sedum in Bobart's house hath grown up these 8 years only by taking of ye cloth now and then and anointing itt with oil once a quarter and soe putting itt on againe." "May ye 9 An^o Domini 1661 att ye Physic Garden Jacob told mee there is a gentleman in Worcestershire who hath made very considerable progres in altering flowers artificially, hee knows not his name." "Rhubarb now may be bought for about 16s."

or 18s. ye pound." "Bobart had a Bunch of Grapes once ripe on ye 5 August wch hee presented to ye Swedish Ambassador, then att Oxford. Hee brags much of itt still, they usually not soe till ye latter end of August or ye beginning of September." "Jacob says hee thinks Parkinson hath 500 plants more than Gerard; only Gerard's paper is better and his cuttis better, they being dulled ere they came into his hands." "Jacob Bobart spake with Dr. Modesay and says of him, ye whole world yields not ye like man: hee never heard any man talk att yt gallant rate in his life: hee showed ym all his designs in ye new Garden. There are to bee walks in itt of thirtie feet wide as hee saies."

ANATOMY AND PHYSIOLOGY.

There is an interesting note written in the year 1652 which is valuable, as it affords a test of Ward's accuracy in reporting what he heard. It is interesting because I imagine it formed a part of the talk at the M.A. table in Christ Church Hall, "our table," as Ward calls it, on some afternoon when Glisson had paid a flying visit to Oxford. You will remember that Glisson was one of the original members of the Royal Society, that he was Regius Professor of Physic at Cambridge and a graduate of the University of Oxford; that he first wrote on Rickets and afterwards on the Liver, the capsule of which is still called by his name. A disciple of Harvey, he was "omnium anatomicorum exactissimus." Of him Ward wrote:—

Asserit Glissonius fuisse Jolivium quendam sibi amicum qui affirmavit dari 4tum genus vasorum distinctorum ab arteriis venis et nervis ut in toto corpore communicationem ejus munus esse aquosam humorem continuo in toto corpore distribuere.

Glisson says that Jolivius, one of his friends, stated that there was a fourth kind of vessel distinct from the arteries, veins, and nerves, so connected throughout the whole body that their function was to distribute a watery humour through the whole body.

In 1654, two years after Ward had recorded the story, Glisson published his book "*Anatomia Hepatis*," in which the following passage occurs. He is writing of the Lymphatics of the Liver:—

Incidi primum in eorum notitiam indicio D. Jolivii idque anno 1652 sub initium Junii: quo tempore ille Doctoratus gradus adapturus, me Cantabrigie in eum finem convenerat. Asseruit nempe dari vasorum 4tum genus, a venis, arteriis nervisque plane diversam idemque ad omnes aut plurimas saltem corporis partes distribui et humorem aquosam in se complecti.

My attention was first drawn to them by Mr. Jolivius about the end of June in the year 1652, at which time he was incorporated to the degree of Doctor when I was at Cambridge, and he came to me for that purpose. He stated, forsooth, that there was a fourth kind of vessel clearly distinct from the veins, arteries, and nerves, and that these vessels were distributed to all, or at any rate to most of the parts of the body, and contained a watery humour.

This observation seems to have borne good fruit, for Ward made some original observations and bought himself a microscope. In 1658 he records that:—

Dr. Willis and Dick Lower opened a Dogg and they first let him blood in the jugulars to discover whether arterial and venal blood did differ in colour and constitution. Mr. Francis told me that he and Dick Lower found much chyle extravasated.

Dick Lower was Richard Lower, whose name is still familiar in "the tubercle of Lower." He was one of the most gifted of the younger generation at Oxford to which Ward himself belonged. Born in 1631 he entered Christ Church in 1649 and took his degree two years later than Ward. He studied medicine under Willis—the circle of Willis—and assisted his master in the dissections of the brain and nerves which have rendered his name immortal. Lower was especially interested in the movement and colour of the blood and of the chyle. Later in life he lost a good deal of practice owing to his Whig tendencies, but as he left £1000 to St. Bartholomew's Hospital he must have done well.

Original Scientific Investigations.

Lower exercised a singular fascination upon Ward and it is clear that he assisted in some at least of his investigations in a truly scientific spirit. Here are some illustrations taken at random.

"Dick Lower is answering ye fellow that writes against Willis." "Remember to buy Dr. Willis 'De Cerebro' for one book and ye fellow's that wrote against Dr. Willis for

another." [This no doubt was Edmund O'Meara's work against Dr. Willis' work on fevers.] "Remember in all my dissections to aim at ye discoverie of a passage betwixt ye stomach and bladder." "I look upon ye blood as all other bodies to consist of three parts, ye thickest part which is first strained away in ye spleen, by ye arteries, ye thicker next that is strained off in ye liver, and ye thinnest of all after that in ye bodie or ye kidneys. These certainly are ye use of these 3 parts, though Highmore makes ye spleen to be a kind of a focus [furnace] to ye stomach to impart heat to it, and ye very consistence or hardness and porosities of whose part does argue as much."

There are several other references to the spleen and its uses, so that Ward had this organ under consideration for a long time. Thus, at one time he was asking himself—

Whether when there is a redundance of ferment in ye stomach and spleen this ferment may not passe along with ye aliment and in several parts, especially ye joints, may not be laid aside again and so cause ye gout.

And again—

Whether ye spleen borrows its ferment from the stomach or the stomach from it: Qy. whether a too much ferment in ye stomach is not ye true cause of ye cardialgia together with wind and some other things.

Such theories were probably inspired by Dr. Willis, but the practical influence of Lower can be seen in—

Things to be inquired into in dissecting Mr. Toone's dogg: at first whether his spleen is any whit grown again since it was taken out; 2ndly whether its dulishness does not proceed from ye ill crasis of his blood not being duly fermented and heightened by ye fermentation of ye spleen.

In another instance he notes that—

A dog's spleen taken out by Mr. Day, afterwards ye same spleen and ye dog was stole by Mr. Hartford and brought up to London and there dissected.

Other evidence of experimental work in a scientific spirit is seen in the statements that—

"The recurrent nerves in a dog's neck being cut ye dog afterwards could not bark." "Mr. Lower cut a dogges wind-pipe and let him run about. Hee had a week so hee could not smell, but would eat anything as I am told." "When one would discover ye ductus chyloferus of Pecquet presse ye Mesenterie somewhat hard and a thinne pellucid liquor will come out at ye top." "The nerves have their original rather from ye cerebellum or medulla oblongata cerebri than from any other part." "Inquire whether there is any such thing as a woman having a suture down her forehead as people commonly report. I searched 34 skulls or thereabouts and of these all, I found but 4 wch had a suture downe ye forehead to ye very nose: another wch seemed to have a squamiferous suture upon ye vertex and which I admired much att. I suppose nature does vary in such things and I wish I could discover something of her operations, especially whether epileptick persons have any sutures."

An equally good piece of original work, putting theory to the test of experiment, also due to Lower's influence—for he afterwards published a work on the subject—is the following:—

"View ye blood of all animals as to its thickness or thinness: yt of Turkies seems to me to be very thick." "Turkey's blood again a 2nd time observed and found to be thick immediately after its being out, wch well might bee in regard of its fulness of spirits wch soon flies away and so leaves ye masse very thick, or whether ye blood naturally is thicker yn that of other animals. Remember to kill a turkey and another fowl together and observe wch blood soonest coagulates."

MEDICINE AND PHYSICIANS.

The extracts relating to medicine and physicians are numerous, and show that practice had not advanced, and was not being investigated in the same way as anatomy and physiology. Symptoms, of course, were alone treated, and often by a nostrum.

"Dr. Wagstaff hath a water made of Roman vitriol and plantain water. He calls it aq. coerulea." "Dr. Wagstaff uses Mastick pills very much and amongst them oil of aniseed for the stone." "Mrs. Woolmer having a great weakness one time when she lay in, Dr. Wagstaffe applied cantharides to blister the inside of her foot and so draw, and drew three days untill letting out ye blister. At last she had a sore in ye place and a Lameness which she could never recover afterwards. She hath since had a numbness or palsie on one side of her head and bodie, but it hath passed away presently without any considerable matter of damage." "Inquire of Mrs. Woolmer whether ye numbness

she complains of is on ye side where ye blisters were used and again advise her to keep open her issue in the other leg and stop it up in that which hath ye sore running in it." A good many years later "Mrs. Woolmer had a tympanie. Att last it inclined to breaking and rose to a head about her navel and one day she runne a pinne into itt and itt streamed out extremely. Her advice with Mr. Hall, who wished her to lie on her back and let it out by degrees, after they got a tapp. A quarter of a year, with much stench and filth, after yt closed up and well." "Dr. Wagstaffe calls Laudanum extractum hypnoticum and extractum cordiale."

Ward died a bachelor, but he seems from the following extract to have learnt something of the wiles of women:—

Dr. Wagstaffe's daughters have a cosmeticke wch would make ye skinne peel off a little and after they looke very fair: only they kept in every time they used it about 2 or 3 dayes: and once in 6 months they used it.

As an illustration of the methods of contemporary practice he states:—

Dr. Willis imparts his receipts chiefly to 2 Apothecaries in Oxford so farre as I can perceive, Mr. Hazlewood and Mr. Crosse. Hee hath a syrup of sulphur wch hee makes much use of. It is his owne composition and no Apothecarie hath itt or knows itt but ye two forementioned. Itt may be taken and is so usually with a Liguorish stick. It is a compound not above 4*l.* an ounce, but it is most used in Colds and distempers of the Lungs.

Two ounces and a half of quicksilver given by Dr. Conyers to a patient yt was troubled with ye black passion. Itt is very good for yt distemper. Dr. Willis uses to give more: ye more you give ye less is ye danger. Itt does by its own weight passe quickly. Doe but mix itt with a plaister and heat itt a little and presently itt flies away, but boyling hurts itt not at all.

Dr. Conyers, born 1622, was educated at Merchant Taylors' School, was a Fellow of St. John's College, and took the degree of M.D. at Oxford in 1653. He was one of the few physicians who remained in London during the Great Plague, says Munk, and fell a sacrifice to it. Of Dr. Conyers, Ward also says: "Hee uses nothing else almost but his emetick powders," and that "he knows some families yt for many years, they say some hundreds, have not had ye pocks: and see it is not in ye blood of ye mother."

References to Sydenham, Willis, and Ent.

There is a short reference to Sydenham in the passage—

There was a great phlogosis in ye Duke of Cambridge his bowels. Dr. Sydenham kept ye Duke of Cambridge alive 3 weeks and the Dutchess thought hee would really have cured him. Hee did itt by some cooling water or other wch hath got him some credit. Hee was also with Sir Richard Bishop for his gout but did little except pultisse him with milk and crumb of bread. He advised Mr. Bishop to fast one day in a week for his rheumatismus so as yt humour would spend ittself.

Of Dr. Willis he says:—

My Lady Windsor is dead: her brain was good as Dr. Willis said, but her liver was rotten and corrupt much. Dr. Willis lays much store uppon ye brain nowadays.

The relationship of Willis to Lower is well shown in the fact that—

"Dr. Lower found out ye famous well near King's Sutton though hee was willing itt should goe under Dr. Willis his name." "Dr. Willis hath got a new way of opening ye Brains, as to cut them on all parts from what holds them and so to turn them upside down."

Of Willis, too, he tells the following story:—

Stephen Toon's rupture was laid open, as ye phrase is, and caused a peristaltic motion of ye guts. At last eased by a plaister and a grain of laudanum wch Dr. Willis said hee was too weak to take, the Dr. left him with these words: "Stephen, God comfort thee."

Stephen Toone did not die of his rupture. He was the apothecary with whom Ward lodged in Oxford. He was the son of Thurstan Toone of Collingborough, Northants, and was "Privilegiatus" 14th September, 1666, aged 30. His will was proved at Oxford 1st October, 1681. The teaching of Willis and Lower is again exemplified in the passage:—

Some Drs. especially in Oxford now are of opinion yt hystericall fitts are caused by ye indisposition of ye Brain. Most in Oxford, as Mr. Francis said, are of yt opinion and that men have ye same thing which some women have, and that Mr. Eliot had a patient that hadde itt and was cured by anti-hystericall things though hee was a man. That there is no passage for fumes into ye Brain by way of valves.

Sir George Ent, the friend of Harvey, to whom we owe the publication of the "De Generatione," is mentioned more than once.

"I heard that Dr. Ent going to Warwick Castle, my Lord Brook having a man very sick of ye griping of ye gutts, My Lord asked ye Dr. what was good for itt. He answered white wine plentifully drank if itt was not too sharp would doe itt, hee would lay his life of itt." "Dr. Ent said to Mrs. Lucy one time when she was sick yt hee had intended to have let her blood, but afterwards perceiving shee had ye jaundice hee said hee would not for a hundred pound yt hee had done itt."

Dr. Bate and Scurvy-grass.

There are many references to Dr. Bate, whom Ward always calls Bates, of New College. He practised in and around Oxford, especially "among precise and puritanical people, he being then taken to be one of their number." He moved to London, was physician to the Charterhouse, and attended Cromwell in his last illness. At the Restoration he became physician to Charles II., and dying in 1669 was buried at Kingston-on-Thames. Ward says:—

I have heard that Dr. Bates writt few bills wherein hee did not prescribe scurvy grass, hence some have styld him in my hearing, as relating itt for others, ye Scurvigras Dr., imagining, I suppose, there might be a tang of itt in most diseases.

Anthony Wood (Life, i., 273) says that scurvie grass drink began to be frequently drunk in the mornings as a physic drink in March, 1659. Ward says, "Put a quart of scurvy grass all fresh to 3 gallons of ale, if strong put in more."

There is an account of Bate in *Longman's Magazine* for August, 1894, pp. 364-75. "Dr. Bates told Dr. Barke that he had used ragwort with scabby people in ye hospital for 40 years with good success." He might therefore have said, as did Dr. Ballard to Lady Peniston, "Madam, I could advise you to a chymical medicine wch should cost you 10 shillings, but I am a friend of what grows under a hedge." "Mr. Hodges of Gloucester was sick of a kind of pthysic and hee consulted Dr. Bates, who prescribed him first a kind of Almond milk, then a wash of oil of Almonds and after ye chewing of tobacco to make him vomit and this cured him cleverly. After ye eating of oil and hony much gravel came away from Mr. Hodges as appeared by his urine."

Dr. Dickenson and the Use of Antimony.

He records the following case, which was under the care of Dr. Dickenson, Linacre lecturer at Oxford and of Eton and Merton Colleges.

Mr. Gwinne of our house vomited up long pieces of blood wch had heads like fishes. They carried them to the Apothecaries and cut them but knew not what to make of them.

A few pages later comes the end of the case—

I saw Mr. Gwinne of our house dissected but could perceive nothing in him that might cause his death, his spleen was somewhat flaccid, so was his heart and one of his kidneys, but his lungs had some kind of scyrrhus in them and in these scyrrhuses a sabulous kind of matter, but that could not kill him. They pretended hee had a contusion of the liver in regard ye concavity of it was a little stained or possibly itt was nothing else but a settling of ye blood when death came. There was a membrane coming from his side to his lungs on each side wch some ignorant people would have interpreted a growing of ye lungs to ye side, but Mr. Boghill said he had seen itt severall times in sound men yt hee had opened. His heart was large, about as large as ye heart of an ox but not perisht at all.

Edmund Gwynne, "serviens," matriculated from Christ Church on July 25th, 1655. The post-mortem examination shows that he had suffered from a tuberculous pleurisy with a dilated right heart, and the long pieces of blood may have been formed in a dilated bronchus. "Mr. Gwinne of our house" was under the care of Dr. Dickenson, the physician who tried to prove that the Greeks borrowed the story of the Pythian Apollo and all that rendered the oracle of Delphi famous from Scripture and especially from the Book of Joshua. Dr. Sheldon thought so highly of his work that he recommended its author to devote himself to divinity and take orders. Dickenson preferred, however, to study chemistry, a subject in which he soon became *facile princeps*. After practising in the High-street, Oxford, he moved to London and became physician in ordinary to Charles II. and afterwards to James II. Troubled by old age and stone in the bladder, he died in 1707, and is buried in St. Martin's-in-the-Fields.

Ward records in another passage that—

"Antimonie:—Mr. Boghill made a balsam of itt wch hee gave to one whose lunges were distempered with excellent success. Hee spake with a great chymist who said if one could take away ye vomiting part of itt and make itt a medicine purely purging downward itt would be a great thing; now Crosse said Dr. Dickenson gave a Lady a pill wch worked 20 times without making her sick and hee told mee confidently yt there was nothing but Antimonie in itt. Hee highly commends Dr. Dickenson for his strong pains taken in prosecuting of itt, and says that certainly hee hath admirable remedies." "Mr. Boghill hath his elaboratories about Chelsey."

Boyle, it will be remembered, lodged with Crosse the apothecary in the High-street, Oxford. Of Turner Ward tells "a merrie storie," "Dr. Turner being to bee examined by ye College for his admission thereto ye young Dr yt examined him askt him how many chapters there were in such a book of Galen? Hee made answer yt he had read Galen before he was divided into chapters." This Dr. Turner was probably John, a Doctor of Medicine of Leyden, who was admitted a Licentiate of the Royal College of Physicians on June 4th, 1630.

"Mr. Topham of Christ Church if hee sat at disputations with his hat off hee used to pisse blood." This was, I suppose, a case of paroxysmal hæmoglobinuria, the attack being precipitated by a chill. Mr. Topham was Richard Topham, B.A., incorporated from Trinity Hall, Cambridge, on Dec. 6th, 1652. He took the degree of M.A. from Christ Church on Dec. 11th, 1652.

SURGERY.

Ward kept himself abreast of the surgery of his day, for he says: "Remember to bring Woodal's Chirurgerie, he was a rare fellow in his time doubtless." This was John Woodall, surgeon to the East India Company and author of the "Viticum or Pathway to the Surgeon's Chest" as well as "The Surgeons' Mate"—the two text-books of naval surgery for many years. "Remember to purchase as soon as possible Pareus his chirurgerie and Mr. Woodall and in the meantime to borrow Woodal of some of my parish." *Paré*, translated by Johnson, was published as a second edition in 1649. Ward also supplied himself with surgical instruments, as is seen in the note: "Remember to get a speculum oris and other instruments fit for chirurgerie when I goe to London and a great case to hold them." He did not aspire to a great armamentarium, for—

"I saw one day all Gill's instruments and hee told mee ye names of ym all and their use and what ye whole case cost him: hee wanted a small spoon and some other things in ye case: yt and his Lancets and his syringe and his salvatorie were all ye necessarie tools of a chirurgion." "Gill said yt Mr. Day hath amputated 5 armes, 3 legges and somewhat else since hee came to him and but 1 of all these died and hee was a person of 60 years at least." "There are two of ye Molines in London. Ye one Edward ye eldest is excellent at stone-cutting and curing of fistula in ano or Lachrymale; ye other Gill told mee is ye better chirurgion. Hee told mee very many pretty stories of his exquisiteness in dissecting bodies wch hee saw admirably performed, taking out ye muscles and letting ym only hang by ye tendons by wch they were inserted. Mr. Moline hath a great many excellent cutts and pictures of ye liver and other inward parts."

Some Surgical Cases.

He gives a graphic account of the surgical treatment of the time:—

A man coming out of a bed by chance jabbing his bare breech down on ye side of ye bed a needle ran up his breech just by his anus. Hee sent for a surgeon of Abbingdon to pull it out and hee catching hold of itt with his forceps but not being able to hold itt but itt slipped and afterwards attempting itt hee thrust itt in further within ye cuticula. After wch Mr. Smith, an Oxford Chirurgical, was sent for; but ye fellow had made an incision and cut ye hæmorrhoidal veins wch bled abundantly att wch ye fellow, being discouraged, threw down his instruments and ranne away leaving him bleeding. They got a woman in ye town to dress him. Smith could see no signe but went and made a great incision 2 inches deep in ye Membrana adiposa and thrust in his finger and turned itt about and felt it; then getting an instrument under hee drew itt out cleverly and gave itt him. Ye fellow when he sawe itt, tooke him in his arms and kisst him and made exceeding much of itt. Hee made not his incision betuixt ye needle and ye anus as did ye other fellow but on ye outside and so no danger of ye sphincter.

Abbingdon is a good seven miles from Oxford, so that, by the time the double journey had been accomplished, to get Surgeon Smith to the patient some hours must have elapsed. Mr. Smith, the Oxford surgeon, also appears in the following passage:—

A way to stop a flux of blood. Take long needles and take up ye flesh first on one side ye vessel, yn beyond on ye other side and soe drawe ye flesh over itt and itt stopps. But itt seems an odd kind of way, tried by Smith ye Oxford Chirurgical in one, but hee died.

A Case of Tumour of the Breast.

Here is the treatment of tumour of the breast:—

* A cancer in Mrs. Townsend's Breast of Alverstton taken off by 2 surgeons the one's name was Clark of Bridgnorth, another's was Leach of Sturbridge. First they cutt ye skinne cross and laid itt back; yn they workt their hands in ytt one above and ye other below and so till their hands mett and so brought it out. They had their needles and waxt threads ready but never used them, and also their cauterising irons, but they used them not. Shee lost not above ʒvi of blood in all. Dr. Needham coming too late staid ye next day to see it opened. Hee said itt was a Meliceris and not a perfect cancer, but it would have been one quickly. There came out a flow of a great quantity of waterish substance as much as would fill a flaggon. When they had done they cutt off one one bitt and another another. Put a glass of wine in and some lint and so let itt alone till next day. Yn they opened itt again and injected Myrrhe, Aloes, and such things as resiste putrefaction and so bound itt up again. Every time they dressed itt they cutt off something of ye cancer yt was left behind. Ye chirurgions were for applying caustick, but Dr. Needham said "No, not till ye last, since she could endure ye knife." They prepared her bodie somewhat, yn let her blood ye day before. She endured it with infinite patience all along, not offering to lay her hand uppon itt to ease itt, but a warme cloth to ye other breast all ye time.

One of the chyrurgeans told her afterwards that shee had indured soe much yt hee would have lost his life ere he would have suffered ye like; and ye Dr. said hee had read yt woman would indure more yn man, but did not belevee itt till yn. The way how and where itt should be cutt away was markt out with Ink by one Dr. Edwards, who lives at Bridgnorth. Mrs. Townsend likt him very well. Hee said if they could prevent a Gangrena there was little fear, but it might be a cure iff she fell not into a feavour.

The extract is interesting as showing how completely the surgeon was subordinate to the physician. The case was clearly one of Brodie's tumours of the breast, so that Dr. Needham was correct in saying it was not a true cancer. Caspar Needham, of Peterhouse, Cambridge, took his M.A. in 1648, and then went to Oxford for the sake of the public library, and was incorporated 1655. He was one of the early Fellows of the Royal Society, and died at the age of 57 in 1679. He is buried in St. Bride's, Fleet-street, but nothing more is known of him. Dr. Edwards was Richard Edwards, of Bridgnorth, who was admitted an extra-Licentiate of the Royal College of Physicians on Dec. 19th, 1662.

There is a good instance of a long-standing pathological error in the next note about a patient who clearly had tetanus.

A worme in ye Gutts caused such a convulsive motion in one yt hee carried his heels and his head violently backwards, and so carrying his bodie into a roundness tumbled up and down with groaning.

WARD'S MEDICAL OBSERVATIONS AND SACERDOTAL DUTIES.

Ward must have had a singularly bad memory, for sandwiched between these details are such entries as, "Remember to excommunicate ye 2 persons yt committed Adulterie: ye woman yt turned Catholick: and to (warn) drunkards and ye like." The warning seems to have taken the form of a sermon, for a few lines farther on he says, "Remember to preach on 35 Jeremiah 14, 15, and to prove yt man is readie to obey man rather yn to obey God." The text is:—

The words of Jonadab the son of Rechab, that he commanded his sons not to drink wine, are performed; for unto this day they drink none, but obey their father's commandment: notwithstanding I have spoken to you, rising early and speaking; but ye hearkened not unto me.

I have sent also unto you all my servants the prophets, rising up early and sending them, saying, Return ye now every man from his evil way, and amend your doings, and go not after other gods to serve them, and ye shall dwell in the land which I have given to you and your fathers: but ye have not inclined your ear, nor hearkened unto me.

Sometimes it would seem that his medical observations must have interfered with his sacerdotal functions, or at any rate that his attention was divided, for—

"A woman yt died in childbed. I saw her just before shee departed. Shee was much troubled with convulsive motions wch are twitchings of the heart just before her expiring." "Full-chested people are long a-dying as was observed in Mrs. Williamson and such people as they are long in dying so are they long likewise ere they come to die." "Remember to write to Mr. Francis for a reason why a blow under the ear kills so suddenly rather yn in another part." "One used to say of his patients that when they were ill they are saints and when they are well they are devils."

HUMOROUS STORIES.—FOLK-MEDICINE.

He was fond of good stories, thus: "One seeing Dr. Bailey goe by a shop in Oxford said instantly, 'Why, there goes ye Dean of Swarum instead of ye Dean of Sarum.'" Dr. Richard Baylie matriculated as a plebeian from St. John's College July 3rd, 1601, aged 15; D.D. July 16th, 1633; President 1632; expelled 1648; restored 1660. Chaplain to King Charles I. and Laud; Archdeacon of Nottingham 1628; Dean of Salisbury 1635; died 1667. The extract throws a light on the Dean's language.

One having to say something in the close of a funeral sermon in commendation of ye person deceased he began itt thus: "It is an old saying De mortuis nil nisi verum. It was Mr. Doolie's brother of Alverston at ye death of our Mr. Lane who lived in Mr. Bishop's house."

Dr. Prideaux said of ye man in ye Gospel yt made excuse because hee had married a wife: says hee, What a fool was hee not to bring his wife with him for yn he had been ye more welcome.

Remember when I goe to London to buy Gusman and Jacobus de Voragine and some other such merrie authors to peruse in winter nights and keep up cheerful innocent mirth.

My Lord Paget seeing a little bit of mutton in a great platter of pottage put off his doublet. Itt being askt what hee intended to doe hee told them hee intended to swimme for ye bit of mutton. This I have heard.

Here and there pieces of folk-medicine are given, as:—

Children get ye Nephriticke disease by pissing in ye fire-place say nurses; and some say to pisse in a pot where some man hath pissed before is doing wrong, ye spirits without communicating with those within.

This appears to belong to the same class of superstition as the preservation of nail-parings and hair-clippings.

"Advise Mr. Benjamin Trapp to touch his swelling in his wrist with a dead man's hand wch may gett itt away." "For a person yt hath lost his stomach injoyne him every morning to eat a piece of Cheshire cheese strong of ye Rennet." "I have seen Cobwebs prescribed inwardly to be taken in conserves of red roses in a Bill (prescription) at Mch Potters, Nov. 28, 1658."

CONCLUSION.

I have entitled this Part I., as it only deals with the first six volumes of the MSS., and owing to pressure of work it has been impossible to make myself acquainted with the remaining ten. These six volumes I have transcribed myself; the rest have been abstracted by Mr. Bethell, your indefatigable Registrar. I hope in the future to deal with his work, for he tells me that it is full of interest; indeed, did time allow there is much that could have been added from the note-books I have read. They show us Ward as an epitome of his age, well read, quite clear in his opinions, with knowledge based on experiment, and yet with a naïve credulity which is surprising until we recall how little was known for certain and how much that is now certain had still to be learnt. His religion, so far as can be ascertained, dealt more with the broad aspect of truth and morality than with any speculative theology. His object was clearly to help his parishioners in their daily trials rather than to teach them the mysteries of the faith.

THE LATE MR. W. A. MEREDITH.—Mr. William Appleton Meredith, M.B., C.M. Edin., F.R.C.S. Eng., who met his death last week as the result of a fall from the skylight of his house at Little Massingham Manor, King's Lynn, was consulting surgeon to the Samaritan Free Hospital for Women in Marylebone-road, London. He was for thirty years on the active staff of this hospital, and published in our columns in 1897 the result of 250 operations for ovarian tumour. Mr. Meredith sat on the bench for the county of Norfolk. He was a native of New York naturalised in this country.

TRENCH FEVER:

A RELAPSING FEVER OCCURRING AMONG THE BRITISH TROOPS IN FRANCE AND SALONICA.¹

By ARTHUR F. HURST, M.A., M.D. OXON.,
F.R.C.P. LOND.,

PHYSICIAN TO GUY'S HOSPITAL; TEMPORARY MAJOR, R.A.M.C.; LATE MEMBER OF MEDICAL ADVISORY COMMITTEE (M.E.F.) AND CONSULTING PHYSICIAN TO SALONICA ARMY.

AFTER all examples of the well-defined acute fevers had been separated from the cases of fever occurring in the British armies in France and in Salonica a considerable number remained in which the diagnosis was doubtful. A few were probably due to infection with *B. paratyphosus*, or even *B. typhosus*, although all bacteriological examinations had proved negative; but I do not think that these should amount to more than 5 per cent. of the cases in which bacteriological confirmation is obtained. The cases left over are most frequently diagnosed as "pyrexia of unknown origin," influenza, and rheumatic fever, the first of these being the only diagnosis which is indisputably correct. A small number of cases of true influenza with the characteristic catarrhal and general symptoms undoubtedly occur, although an attempt is rarely made to confirm the diagnosis bacteriologically. Rheumatic fever is rare. Herringham only saw five cases in France between October, 1914, and October, 1915, though it subsequently became rather more common, and I only saw a single definite case in Salonica; in the few cases so diagnosed, in which the pain is really localised in the joints, the arthritis is almost always gonococcal and not rheumatic. We are thus left with a number of cases of pyrexia of unknown origin. In this paper two varieties of a well-defined febrile disease are described, which account for a considerable proportion of these cases.

In the early summer of 1915 Major J. H. P. Graham drew attention to a type of fever occurring in the British Army in France, in which two periods of pyrexia were separated by a normal interval. Similar cases were recognised with increasing frequency, and the disease soon became widely known as "trench fever." In November, 1915, Captain G. H. Hunt and Major A. C. Rankin described 30 cases of the same type of trench fever, and a still fuller account was published in February, 1916, by Captain J. W. McNee, Lieutenant A. Renshaw, and Captain E. H. Brunt, in which for the first time two distinct clinical types of the disease were distinguished.

The disease was only observed among officers and men living near the trenches and in the personnel of hospitals, especially among orderlies of wards in which there were patients suffering from the disease. No cases occurred among ammunition columns, ordnance and headquarters' troops. It was for this reason that the name "trench fever" was adopted, though actual residence in the trenches themselves was certainly not an essential factor, and Hunt and McNee in their most recent communication state that cases have recently been met with further from the front.

According to Colonel Sir Wilmot Herringham, literally thousands of cases of the first type occurred among the troops in France and Flanders between the end of April and October, 1915; it was comparatively rare in the following winter, but increased again in the spring of 1916. It did not occur in Gallipoli and was not definitely recognised in Salonica until April, 1916. The second type, which was rare in France and Flanders until November, 1915, when it became more common than the first, has been very prevalent in Salonica since December, 1915. At first cases had to be recorded as "P.U.O." (pyrexia of unknown origin) or under the head of "influenza" or some other equally incorrect name, even when their nature had been recognised. For this reason it became customary to call the disease "pyrexia of unknown origin (A)," or shortly "P.U.O. (A)," as this designation did not introduce into the official records an unauthorised name, such as "periodic one day fever" or "Salonica fever," which had been used by some medical officers. The term "trench fever" was not used, as, besides being an unauthorised name, the disease was

¹ Amplified from an address given to the Salonica Medical Society in April, 1916.

common in Salonica at a time when no men were living in the trenches, and cases occurred in ammunition columns several miles from the trenches as well as in front line troops and among hospital attendants. When, however, in March, 1916, we recognised that the disease was identical with the long form of trench fever described by McNee, Renshaw, and Brunt, and when a month later the common short form of trench fever seen in France and Flanders became prevalent in Salonica, it seemed wise to adopt this name.

A few cases with symptoms intermediate between the two types of trench fever have been observed in France and in Salonica, and the initial symptoms are very similar, but the temperature chart is so different in typical cases, and the second class occurred in such large numbers without the first in the winter months, although it was very rare in comparison with the first during the summer of 1915 in France, that it cannot yet be regarded as definitely proved that the two diseases are really due to the same infection, as is generally believed by British observers in France.

My attention was first drawn to the disease in Salonica at the beginning of January, 1916, by Lieutenant-Colonel D. J. McGavin, Major D. S. Wylie, and Major H. T. D. Acland, of No. 1 New Zealand Stationary Hospital. At first it was not widely recognised, but as medical officers became more familiar with its characteristics it became clear that it was extremely common, especially in certain units.

With the exception of one man, who contracted the disease whilst in hospital from another cause, all of the cases observed in Salonica up to March, 1916, belonged to divisions which had been several months in France. None had been in Gallipoli or Serbia. The short form of trench fever had occurred in several of the affected units whilst they were in France. It is highly probable that these divisions brought the infection with them. In March, 1916, the long form of trench fever began to occur in a division which had been in Serbia, but not in France. Some of the men had been in Gallipoli, but most had come straight to Salonica from England. In April groups of cases of both forms of trench fever appeared in units belonging to other divisions, which had been free from the disease since their arrival at the end of 1915. The later cases probably became infected by men coming in drafts from France. The disease also developed among the personnel of some of the hospitals to which the patients were sent. It does not appear to have been observed among French troops either in France or Salonica.

Early in 1916 cases of the first variety were observed in Austrian troops in the Tyrol, and cases of the second variety in a German field hospital on the Eastern front.

Pathology.

Before trench fever could be accepted as a clinical entity it was necessary to prove that it was not an aberrant form of some other condition, such as paratyphoid fever, which it may closely simulate during the first pyrexial period, true relapsing fever, which it resembles in so far as the fever is of a characteristic relapsing type, and malaria, which is sometimes simulated by the shorter and sharper pyrexial attacks. But the blood taken at the height of both the initial and the later febrile periods has always been sterile on cultivation, the Widal reaction has been consistently negative at every stage of the illness, and no spirochæte or malarial plasmodium has been found in spite of repeated examinations of blood films taken both during febrile and afebrile periods.

McNee and Renshaw found that trench fever could be transmitted to healthy soldiers by the intramuscular or intravenous injection of the blood of men suffering from the disease. Injection of the washed red corpuscles had the same effect, but the plasma and serum were not infective.

One attack does not seem to protect against reinfection. I saw a man with the long type of trench fever in April, 1916, in Salonica; he had been seen by Captain McNee in a typical attack in September, 1915, while in France, and had been quite well in the interval. It is possible, however, that there was no reinfection, the original infection having remained latent between the two attacks.

As all attempts to discover the infective organisms have failed and as no fatal case has occurred, the nature of the disease remains unknown. The striking periodic character of the fever in the long type of case, the considerable increase in the proportion of large mononuclear leucocytes

which has been found on several occasions, and the evidence pointing to an intracorporeal infection suggest a protozoal rather than a bacterial origin.

Method of Propagation.

There is no nasal, pharyngeal, or bronchial catarrh, and, except for constipation, gastro-intestinal symptoms, though occasionally well marked, are generally completely absent. It is probable, therefore, that the disease is not conveyed by the respiratory secretæ or by the fæces, but through the intermediation of some insect. The occurrence of the long form of the disease during the winter months shows that the infection can be conveyed in the absence of mosquitoes and other flying insects; though Herringham found mosquitoes in France throughout the winter, there were certainly none in Salonica. Fleas have been scarce in both countries, and the men themselves rarely complain of them. Almost all patients admitted that they were lice-infested up to the time of their entry into hospital, so that it is quite possible that the disease is conveyed by lice. A hospital orderly, who had been free from lice since his arrival in Salonica, had to carry the kit of a number of new patients suffering from trench fever on May 2nd, 1916. The clothes were swarming with lice, and the same evening he found some in his own clothes. He got rid of them in the course of a few days, and on May 20th an attack of trench fever began. He was not employed in the wards and he never came in contact with any patients suffering from the disease. He was the first case of trench fever in the personnel of the hospital to which he was attached. The incidence of trench fever is least in the cleanest battalions and in the divisions which have the best facilities for bathing. In some units a successful campaign against lice has been immediately followed by a great diminution in the incidence of trench fever. As a result of the rigorous measures taken in Salonica the disease almost disappeared in the summer of 1916. Captain A. L. Urquhart developed the short form of trench fever after allowing the lice from a patient with this form of the disease to bite him, and Captain McNee tells me that his observations in France have led him to agree with the conclusion I came to in Salonica—that the disease is spread by lice.

Cold, wet, and fatigue appear to be exciting causes in a man who has become infected, but has so far had no symptoms; thus Captain Hay noticed that in almost all cases in his regiment in Salonica the fever began two or three days after the patient had been wet through. In several instances a group of men sleeping in the same tent have been affected.

Some patients appear to be carriers, who do not lose the infection completely for several months, but have recurrences from time to time, during each of which they may infect an additional number of men. A sergeant, who had been in good health whilst in France between December, 1914, and November, 1915, developed the long form of trench fever early in December, 1915, directly after he left France for Salonica; in the following four months he was in hospital five times for a week or more, though he was perfectly well in the intervals. Every time he returned to his unit he became lice-infested again and appeared to infect some of the men with whom he came in contact, about forty men of his company, including six sergeants, having been taken ill with trench fever between January and March; one of the sergeants had wrestled with him, another had danced with him, a corporal slept next to him, and a private sat next to him for some lectures.

Incubation Period.

As a result of observations in Salonica on cases arising in hospital when a patient had been admitted for some other condition, I came to the conclusion that the incubation period is between 15 and 25 days; in the case of the hospital orderly already described it was probably 18 days. Quite independently, Hunt and McNee in France concluded that it was between 14 and 24 days. The following three cases are typical of those which led to my estimate of the incubation period.

CASE 1.—Sergeant — was admitted for rhinitis on Dec. 27th, 1915, into a ward in which there were at the time two patients suffering from the periodic form of trench fever, no other cases of which had yet been observed in his unit. On Jan. 1st, 1916, he was moved into another ward in which there were, and have since been, no such cases. When convalescent from the rhinitis, which had been accompanied by no pyrexia or pains in the head, back, or legs, he suddenly

became ill on the evening of Jan. 24th. His temperature in the morning was normal, but at 6 P.M. it was 104° F. This proved to be the first pyrexial period of a typical attack of the periodic form of trench fever. It was probable that the infection was contracted from the other cases in the ward between Dec. 27th and Jan. 1st, between 23 and 27 days before the onset of symptoms.

CASE 2.—Private — went to France at the beginning of the war with the 1st — Regiment. He was wounded in January, 1915, and was in England until the end of 1915, when he came to Salonica, joining the 2nd — Regiment, which had come there from France in November, on Jan. 13th, 1916. A few days after he arrived he became lice-infested. On Jan. 21st he went to a field ambulance and then to a casualty clearing station with a hydrocele; he was transferred to a stationary hospital on Feb. 6th. On the 12th his temperature rose and a typical attack of the periodic form of trench fever began. His clothes were disinfected when he entered the casualty clearing station, and he had no more trouble with lice after his admission there. It is probable that he contracted the disease whilst with his regiment—i.e., between 24 and 16 days before the onset; as he was not lice-infested until he had been with his regiment some days, the incubation period was probably about 20 days.

CASE 3.—A patient was admitted into hospital for quinsy. He was in a ward in which there were no other cases of trench fever, but he developed the disease 14 days after admission. He had probably contracted it whilst still with his regiment, in which at least one case had already occurred, so that the incubation period was over a fortnight.

Symptoms.

The disease generally begins suddenly without any premonitory symptoms, but a feeling of malaise occasionally precedes the attack for a day or two. The patient complains of severe headache, especially frontal and behind the eyes, and this is rapidly followed by pain in the lower part of the back and on the second or third day in the legs. Pain in the neck is occasionally observed; in two cases mentioned by Hunt and McNee pain and stiffness in this region were so severe that a lumbar puncture was performed in order to exclude meningitis, and I also saw two cases in Salonica in which this was done. The patient generally shivers, but there is never a definite rigor; he is occasionally flushed and often sweats profusely. The bowels are regular or constipated, and there is no nasal or bronchial catarrh; the appetite is lost, the tongue is moist and often slightly furred, and occasionally mild pharyngitis is present. Herpes labialis has occurred in a few cases, but less frequently in the long than in the short form of the disease. There is no rash.

The onset is sometimes extremely abrupt; the patient suddenly feels giddy with a burning head, he shivers and may be very short of breath, and complains of a pain in his left side. He has to fall out if on parade or marching and has often great difficulty in returning to camp without assistance.

In a few cases, in which constipation is generally present, there is some abdominal pain with slight distension and tenderness, and there may be nausea and even vomiting at the onset. Four out of my first 50 cases of the periodic type were sent to hospital diagnosed as appendicitis; in one a normal appendix was removed and a second would have been operated upon had he not refused. The abdominal symptoms rapidly disappeared, and in the relapses they were less prominent than the other symptoms.

When the pain in the legs is severe there may be some cutaneous hyperæsthesia over the shins. In several cases the periosteum of the tibia has seemed to me to be rough and thickened, as it pits slightly on pressure, although no pitting of the subcutaneous tissue was present. The tenderness is most marked over the lower half of the shins and may be very severe, a comparatively slight pressure causing the patient to cry out, and the pain produced may last for hours. A less degree of tenderness is often present in the tendons behind the knee, and occasionally in the ligamentum patellæ and along the course of the femur. The shins are always tender, even if the patient complains of no pain in the legs, but tenderness appears most marked in groups of cases and at certain times. Graham did not mention it, and it was not observed in the earliest cases in Salonica. There is little or no tenderness of the calves or other muscles. The knee- and ankle-jerks are normal.

In the first attack the spleen is sometimes palpable or is found to be enlarged on percussion and there may be some tenderness in the left hypochondrium. Although this was

certainly the case in Salonica, Herringham and Hunt and McNee never found any splenic enlargement in the cases they observed in France.

Leucocytosis is often, but not always, present during the pyrexial attacks; the count varied between 4700 and 22,000 per c.mm. in 35 cases, mostly of the short type, examined in France (Hunt and Rankin; McNee, Renshaw, and Brunt). In many of the cases examined both in France and in Salonica there was a relative increase in the large mononuclear cells (Elworthy, Urquhart). Polychromatophil cells above the normal size, with well-marked punctate basophilia, were observed by McNee, Renshaw, and Brunt in France, but Elworthy, working in Salonica, came to the conclusion that they only occurred in the later stages of the more severe cases. The percentage of hæmoglobin is generally about 80, though the number of red corpuscles is undiminished.

In the *short form of trench fever* the temperature rises rapidly to between 102° and 104° F., but the pulse-rate is only slightly increased. On the third or fourth day the temperature suddenly falls, generally to normal or subnormal, but there is no corresponding improvement in the symptoms. After an interval of a few hours it rises again, and then after another two to five days it falls to normal. On this occasion there is immediate relief to all of the symptoms. (Chart 1.)

CHART 1.

Short form of trench fever.

CHART 2.

Short form of trench fever.

In some cases the remission on the third or fourth day does not occur, the temperature remaining raised for about a week. There is often a single relapse after an interval varying from a few hours to ten days, but generally less than four days. The temperature rises to 100° or 101° for 24 or 48 hours, during which the symptoms return with diminished severity. (Chart 2.) The patient is generally fit for duty almost immediately after the temperature falls again. Many cases have subsequently been kept under observation by Hunt and McNee for weeks or months without any return of fever or other symptoms, so that there could be no question of additional relapses occurring after the patient had been discharged from hospital.

In the *long or periodic type of trench fever* the temperature rises to between 101° and 104° F. on the first evening. The initial attack is variable in duration; the temperature may be normal the first morning, high in the evening, normal the second morning, and rather less high the second evening than the first, after which it remains down. In other cases the first attack may last as long as four or five days, the temperature being always lower in the morning than the preceding and following evening, the highest temperature being reached on the second or third day; in one case it reached 105.8° on the third evening, though it was normal the previous and following mornings. The pulse is generally accelerated in proportion with the temperature, but at first it may be considerably faster. With the fall of temperature at the end of the initial attack all the symptoms disappear, and the patient is often sent back to duty. After being well for two to ten days he complains of a return of headache and pain in the legs, which culminate at night; the temperature rises in the evening to a point which is generally a little lower than the highest temperature in the first attack. The temperature falls to normal or nearly normal the next morning, and either remains down or rises to a less extent the second evening, thereafter to remain normal. The general symptoms are much less severe than in the first attack and the acceleration of the pulse is less marked, but the pain in the legs and tenderness of the shins are generally greater, and they may not disappear completely in the interval between the second and third attacks, though the headache, which generally remains the most prominent symptom during the attack, is never present in the apyrexial periods. The pain in the legs is sometimes extreme and may prevent sleep; in other cases it is comparatively slight

and the patient looks and feels remarkably well, considering that he has a temperature of 101° or more. Recurrences follow periodically, the maximum temperature being always reached in the evening. (Chart 3.) The interval between the height of the attacks is fairly constant in each case,

Diagnosis.

The diagnosis can only be made with certainty from a study of the temperature chart, but the association of pyrexia with tender shins is very suggestive of trench fever already

CHART 3.

Periodic form of trench fever.

but it varies in different cases between four and eight days, five being the most common interval. Each succeeding attack is generally milder than its predecessor, and the temperature is rather lower, but in severe cases the patient feels weaker in the later intervals, and the

in the first attack. Painful and tender shins have, however, sometimes been observed in the Salonica Army in the absence of fever, and the unsatisfactory name of "trench shin" has sometimes been used to describe such cases. Some of the cases regarded as examples of the short form of trench fever are probably really periodic cases, as there is no doubt that the later bouts of pyrexia are often entirely missed owing to the short time they last, the patient having meanwhile gone back to duty or if in hospital the evening temperature may have been taken at 5 P.M., although the rise only began at 7 P.M. or later. Several medical officers, who were very familiar with the early stages of the disease, only recognised the periodic rise of temperature after their attention had been specially drawn to its occurrence, as their patients had returned to duty after the first or second attack and had not "gone sick" for the later and comparatively slight recurrences.

CHART 4.

Periodic form of trench fever. In the fourth attack the rise of temperature was missed at the ordinary hour of taking it.

pain and tenderness of the legs are more persistent. The later attacks may be of such short duration that the rise in temperature is not recorded at all if it is only taken twice a day. (Chart 4.) On the afternoon and evening of the day on which the attack is expected the tem-

perature should therefore be taken every two hours, especially if there is any pain in the head or legs, as in most cases the patient knows from his sensations that there is going to be a relapse, even before the temperature rises. The temperature is sometimes only raised for three or four hours. In one case, for example, the morning temperature was 98° , at 5.30 P.M. it was 99° , at 6.30 P.M. 100° , and at 8 P.M. 101° ; at 9 and 10 P.M. and at 8 A.M. the following morning it was 98.4° .

In another case it was 97.6° at 5 P.M., though the patient had had a headache since the morning, but 101.2° at 8 P.M., 102.4° at 10 P.M., 101.4° at 2 A.M., 100.2° at 6 A.M., and 98° at 8 A.M., so the chart showed no rise, as the temperature in the ward was taken at 8 A.M. and 5 P.M. This liability to miss the rise in temperature accounts for the fact that it may appear from the chart that an attack has been missed, the interval between two of the later attacks being double that between the earlier ones; a headache may have been felt and a rise in the pulse-rate recorded half way between the attacks. In some cases the temperature is sub-normal between the last two attacks, in which it rises to normal but no higher. In a few cases the temperature remains raised for three or even four days in each attack, the evening temperature being always higher than the morning temperature, which may be normal on the first and last days; the highest point is generally reached the second evening. (Chart 5.) In one case the third relapse was of exceptional duration and severity; this may have been due to a relapse having been missed, as the apyrexial period which preceded it was of double length. (Chart 6.)

CHART 5.

Periodic form of trench fever, with each attack lasting three days.

though it was generally recognised by medical officers that they were not identical with the familiar forms of influenza. Thus, there is never any nasal or bronchial catarrh, the patient rarely appears or feels seriously ill, except sometimes during the first two days of the first attack, and respiratory, and nervous complications never occur. The periodic return of pain and pyrexia and the pain and tenderness of the shins are quite characteristic and prevent confusion with influenza except at the onset.

The possibility of malaria must always be considered, and a blood film should be examined for the malarial plasmodium before making a definite diagnosis in cases of doubt, especially when malaria is prevalent or if the patient has previously had malaria. The differential leucocyte count is of no assistance, as there is a relative increase in large mononuclear cells in both diseases. The longer intervals between the attacks, their invariable occurrence in the

CHART 6.

Periodic form of trench fever. The third relapse (marked IV.) of exceptional duration and severity following an interval of double length.

evening instead of at various times of the day, the absence of true rigors and the failure of quinine given by mouth to modify the course of the illness are distinguishing features of trench fever. Several old soldiers at first thought that they were suffering from malaria, but they subsequently realised that the disease must be different, as they never

before had had severe pain and tenderness in their shins.

A few cases of true *relapsing fever* occurred among British as well as Indian troops at Gallipoli, but only eight Indian and no British soldiers had been attacked by the disease in Salonica up to the end of April. The disease was, however, common in the Serbian Army in 1915. It was actually first described by Hippocrates in the Greek island of Thasos; so it is necessary to be on the look-out for it among British as well as Indian soldiers at Salonica, and at least one case occurred in June, 1916. In six cases I saw with Captain F. F. Strother Smith, I.M.S., the pyrexial period was generally longer, varying between two and a half and six days, and the fever was higher than in trench fever, the maximum temperature in each attack being between 104° and 105·6° F. Successive relapses did not diminish in severity unless they were cut short by injecting salvarsan, the effect of which was almost instantaneous. The patients were extremely ill and often delirious during the pyrexial periods, and the delirium occasionally continued after the temperature fell. Bronchitis was common and there was no pain in the legs or tenderness of the shins. The apyrexial periods varied between two and eight days, six days being the most common, but the periodicity was less regular than in the periodic type of trench fever. The spirochaete was found without difficulty in the blood during the pyrexial period in every case. The disease may, however, be less severe when it occurs among Europeans.

Prognosis.

There have been no fatal cases and the patient never appears seriously ill, except occasionally for a very short time in the first attack.

Until the commencement of the hot weather in Salonica at the end of May no complications had been observed, with the exception of phlebitis of the femoral vein in one case and slight jaundice in two cases, but the latter, at any rate, was probably accidental. With the onset of the hot weather it was found that trench fever was often accompanied by a moderate degree of cardiac dilatation, which resulted in the development of "soldier's heart," if the patient returned to full duty too soon. Endocarditis has never occurred. Hunt and McNee have not observed albuminuria, but Herringham found a trace of albumin, which soon disappeared, in a few cases. I know of one case in which albuminuria occurred in Salonica, and I have seen a similar case—a soldier from Flanders—in London.

The total duration of the periodic type of trench fever from the onset to the end of the last attack is generally between four and six weeks, but some cases appear to abort, and in a few others attacks may recur for several months, the patient remaining quite well in the intervals. I saw a sergeant with the periodic form of trench fever in January, 1916, in Salonica; he had had similar attacks at intervals since August, 1915, when he first became ill in France. In most cases the patient rapidly gets strong again after an attack, and is generally fit for duty after the second period of pyrexia, though he may have to rest for a few hours when the later attacks occur. Sometimes, however, great exhaustion follows and convalescence is slow.

Prophylaxis.

As the disease is probably conveyed by lice, which become infected by biting a patient during an attack, every effort should be made to keep troops free from them. All cases of trench fever should either be sent to hospital or isolated, and the patient's clothes and bedding should be specially disinfected as well as that of all men who have recently slept near him. After the initial or the second attack a man is often able to return to duty; it is very important that he should be kept under observation, and if he again becomes verminous his clothes and bedding should again be disinfected. Men who are still having attacks or have recently recovered should sleep together, isolated from the other men in their unit, but there is no reason why they should not work with them.

Treatment.

No treatment has yet been found which prevents the periodic return of attacks or which is really effective in overcoming the pain. It is generally agreed that in the first attack considerable relief occurs if the tendency to constipation is prevented by aperients. Acetyl-salicylic acid is the most effective analgesic drug. Quinine given by mouth

has no obvious effect, but I have found that the subcutaneous injection of gr. x. of the bihydrochloride whenever the temperature rises above 99° appears to put an end to relapses in prolonged cases. Salvarsan and antimony have proved useless. In one severe case Hunt and McNee tried intravenous injections of eusol without success and in two others 20 c.c. of the serum of a convalescent patient were injected intravenously without influencing the course of the illness.

Numerous local applications, both hot and cold, have been used for the painful shins; some of them have appeared to do good in certain cases, but the most frequently successful seems to have been a cold compress of saturated magnesium sulphate solution, which was first recommended by Captain D. S. Harvey. In slight cases gentle massage has given temporary relief. I have recently seen a number of cases with Captain W. R. Reynell, in which considerable improvement followed the use of a galvanic bath with frequent reversals of the current. In a few cases in Salonica the periosteum was incised, but when this was done on one side only, improvement occurred with equal rapidity on the opposite side. Even if the results had been more promising I should regard the operation as quite unjustifiable, as the pain always disappears spontaneously in the course of a few weeks and often quite rapidly even when it is exceptionally severe.

THE OPERATION OF LARYNGO-FISSURE.

SOME NEW INSTRUMENTS SPECIALLY DESIGNED
FOR IMPROVING THE TECHNIQUE.

BY IRWIN MOORE, M.B., C.M. EDIN.,
SURGEON TO THE THROAT HOSPITAL, GOLDEN SQUARE, W., ETC

THE brilliant results obtained during recent years by the operation of thyro-fissure in cases of early cancer of the interior of the larynx, more especially in the vocal cord area, have brought this comparatively old operation more prominently to notice.

An anterior median vertical fissure of the larynx may include fissure of the thyroid or cricoid cartilages, or of both. Fissure of the cricoid alone is probably a very rare procedure. In the treatment of chronic inflammatory stenosis of the larynx a full laryngo-fissure through the thyroid and cricoid cartilages is always performed, and usually the incision extends through some rings of the trachea, thus constituting a laryngo-tracheostomy or tracheo-laryngostomy. In operations for malignant disease, and in very exceptional forms of non-malignant disease, the lesser form of laryngo-fissure—i.e., thyro-fissure—is the operation of choice, the cricoid being left intact. This shorter form of laryngo-fissure is frequently alluded to as thyrotomy, and that nomenclature was not only employed by Butlin and Semon in recording their numerous cases, but their example has been largely followed by specialists and general surgeons all over the world.

Thyrotomy as a term is not free from ambiguity, however, and does not differentiate between incising the thyroid gland and the thyroid cartilage. The same criticism in a lesser degree applies to thyro-fissure. Durham¹ in 1883 expressed his opinion that the term thyrotomy is more applicable to cutting operations on the thyroid gland, and suggested that any operation in which section of one or other or both of the larger laryngeal cartilages is made should be termed "laryngo-chondrotomy." For the sake of clearness Tilley² has both spoken and written of thyro-chondrotomy instead of thyrotomy. Hill,³ in discussion, has suggested that laryngo-fissure should be retained for the full incision where both cartilages are fissured (which is occasionally necessary in cases of considerable subglottic extension of the lesion), and thyro-chondro-fissure adopted for the shorter form of laryngo-fissure.

³ Proc. Roy. Soc. Med., Laryngol. Sect., vol. VIII., Dec. 4th, 1914, p. 35.

In the title of this communication I have employed the term laryngo-fissure in its old comprehensive sense as including both the longer and shorter incisions. The body of the paper is largely concerned with the lesser variety of laryngo-fissure, and this I have alluded to as thyro-fissure, considering it less ambiguous than thyrotomy and a sufficiently well-understood term.

A comparison of the statistics of this operation from 1889 to 1914—i.e., a period of 25 years—shows such great progress, especially during the latter half of this period, that we now expect to obtain a lasting cure in 80 per cent. of cases. The death-rate at the present time has also been reduced to less than 4 per cent., and in the hands of the very experienced and skilled operator to nil. Nowhere in the whole of the realm of the surgery of malignant diseases, says Chevalier Jackson,⁴ have such results been obtained. This success is due partly to the earlier diagnosis of the disease, and partly to improvement in operative procedure.

While diagnosis and technique have improved, there still remains room for a better instrumentarium. Just as in endoscopy the wise selection of instruments may be a great factor of success, so in this operation of thyro-fissure it is important that suitable instruments should be used if we are to attain the best results. The instruments⁵ which I have designed for this operation have been for some years in use,

though they have not yet been formally introduced to the profession, since it was my desire that they should first stand a fair trial. They are now used and recommended by StClair Thomson⁶ and other of my colleagues.

Thyroid gland clamp forceps.—In the preliminary operation of median tracheotomy it is often necessary to separate the thyroid isthmus from the trachea and divide it down the middle line in order to expose the trachea. These forceps are of use in clamping each side of the thyroid isthmus before division and ligaturing. It is advisable to ligature the isthmus on each side after division, even though its vascularity may be only slight, so as to avoid not merely the chance of secondary hæmorrhage, but also risk of acute thyroidism, which has occasionally occurred as a sequel and depends upon the unregulated excessive absorption of thyroid secretion into the system.

Shows the clamp forceps in position and the incisions made in the thyroid cartilage in thyro-fissure and in the trachea. $\frac{1}{2}$ scale.

tions, and for this purpose four of these forceps may be

required. The advantage of this median tracheotomy, which is intermediate between the high and low operation, is that the trachea is not so deep as in the low operation, whilst there is ample room above the tracheotomy tube to allow room for the operation on the larynx.

Fig. 2 shows the clamp forceps attached to the two halves of the thyroid isthmus after separation in the middle line. The figure also shows the incision made by the shears (Fig. 4) in splitting the thyroid cartilage in thyro-fissure, together

Tracheal shears. $\frac{5}{8}$ scale.

with the correct position of the incision in the trachea—i.e., through the third and fourth rings, for the introduction of the tube in the median operation of tracheotomy.

Tracheal shears (Fig. 3).—These are short, sharp-pointed scissors of the turbinotome type. They are useful for tracheotomy in cases where the tracheal rings are ossified, and difficulty is experienced in cutting them with a knife. They are also useful for splitting the cricoid cartilage and opening the lower quarter of the larynx in those cases where more room is required. The point of the lower blade being sharp they can be also used for “stabbing” the trachea if necessary in place of a knife.

Thyroid cartilage shears (Fig. 4).—These are used for splitting the thyroid cartilage at the angle where the two alæ meet in the middle line so as to expose the interior of the upper three-quarters of the larynx, and are also useful in splitting the cricoid cartilage in those cases where there is difficulty in reaching the subglottic extension of the growth and where additional room is required. They are very strongly made and are used in the same way as scissors. They will divide the cartilage with one clean cut without causing any crushing or damage,

Thyroid cartilage shears. $\frac{3}{8}$ scale.

thus avoiding the risk of perichondritis and sepsis, which has in some cases followed the use of other instruments.

The lower blade has a very fine saw edge to prevent lateral slipping during cutting, and is curved and pointed to facilitate its introduction through the crico-thyroid membrane, under the lower edge of the thyroid cartilage, and upwards between the vocal cords. The upper blade is provided with a sharp spike at the extremity of its cutting edge in order to assist in transfixing the larynx and keeping it steady during the cutting. The larynx can therefore be carefully divided through the anterior commissure so as not to injure either vocal cord. The position of the handles in relation to the blades is such that they lie well above the neck, so that the tracheotomy tube already inserted in the trachea does not get in the way of the operator's hands.

Experience has proved the great advantage of these cutting shears over any other instrument used for this purpose. They may also be used in the treatment of stenosis of the larynx by the operation of laryngostomy—i.e., laying open the larynx anteriorly by fissure of the thyroid and cricoid cartilage and keeping it open for a long period of treatment. In such a case they will divide the cartilages, whether ossified or not, and soft parts, including the skin, at one cut.

Fig. 5 shows the correct way of introducing the cutting shears in the operation of laryngo-fissure. The sharp-pointed lower blade of the instrument is seen entering the

⁴ Peroral Endoscopy and Laryngeal Surgery, 1915.

⁶ Intrinsic Cancer of the Larynx after Operation by Laryngo-fissure, Proc. Roy. Soc. Med., Laryngol. Section, vol. ix., Nov. 5th, 1915, p. 8.

crico-thyroid membrane to reach its position between the vocal cords. It also shows the position of the patient's head, neck, and shoulders; the head being supported by an assistant so as to keep the parts in the middle line.

Fig. 6 shows the position of the shears in cutting through the thyroid cartilage. The instrument is removed by releasing the pressure of the fingers on the lower handle, which causes the upper blade to spring back and leaves the lower blade to be withdrawn in the opposite direction to its introduction.

Thyroid cartilage saw (Fig. 7).—This is a small fine saw which is not so cumbersome as those formerly in use. It is intended for partially sawing the larynx before using the shears in those cases in which the upper and lower edges of the thyroid cartilage are ossified, as is so frequently met with in elderly people; or it may be used to saw partly through the whole length of the thyroid angle in the middle line in order to make a groove for the cutting shears. The depth of the saw blade is only 4 mm., so that it is unlikely to do any damage to the intralaryngeal soft parts. The

Shows correct way of introducing cutting shears in laryngo-fissure.

Shows position of shears in cutting through thyroid cartilage.

shaft is bent in such a way that when the saw is used by the operator standing above the head of the patient, the patient's chin does not get in the way of the operator's hands. If it is used from below the operator's hands are well away from the neck and do not come in contact with the tracheotomy tube.

Self-retaining thyro-fissure retractor.—This instrument is made on the principle of an abdominal retractor, and can be used either for the cervical skin incision, the thyro-fissure, or the complete

FIG. 7.

Thyroid cartilage saw.
3/8 scale.

laryngo-fissure. It is most useful for separating the lateral halves of the larynx after they have been split open by the shears and retaining them in any position. With this retractor (Fig. 8) the larynx may be opened and closed, gradually or quickly, with the greatest facility without overstraining or damaging the two separated halves of the

FIG. 5.

thyroid cartilage, as may occur with ordinary hand retractors, and which may give rise to subsequent discomfort and difficulty in swallowing. The retracting hooks may be so adjusted, or one removed on either side, that they do not interfere with the dissection of the growth from the inner wall of the larynx. It can also be used if necessary to hold back the skin and soft parts during the preliminary operation of tracheotomy. It therefore does away with the necessity of one assistant.

Perichondrial elevator.—With this instrument the soft parts together with the perichondrium are raised off the inner surface of the thyroid cartilage as is done in the parallel operation of subperichondrial resection of the septum. As the cartilages are usually ossified in these cases periosteal rather than perichondrial resection would perhaps be the more correct description. It may also be used as a dissector for separating the muscles in the middle of the neck and for raising the thyroid isthmus off the trachea in the preliminary operation of tracheotomy. The handle of the instrument may be passed under the isthmus and used as a director during its division.

Intralaryngeal forceps.—These are especially useful for grasping the growth during its removal with the scissors. They are made with smooth circular unserrated ends which prevent tearing into or crushing the growth, such as may occur with ordinary dissection or tenaculum forceps, and consequently the risk of reinfecting the wound by cell transplantation is avoided. The importance of avoiding this reinfection has been referred to by many writers. Lack,⁷ amongst others, has discussed this matter. Crile⁸ advises that to avoid reimplantation of cancer cells no instrument or sponge that has touched the cancer surface should be used again, nor should they touch anything else that may be used again in the operation. These forceps may also be used for inserting the tethered sponge or gauze into the trachea after the larynx has been opened. They are made either straight or angular (Fig. 9) to suit the convenience of operators.

FIG. 8.

Shows the two halves of the thyroid cartilage held apart by the self-retaining retractor, exposing a full view of the inside of the larynx. On the right vocal cord is seen the growth.

⁸ Operative Surgery of the Nose, Throat, and Ear. By Hanau W. Loeb. Review in Journ. of Laryngol. and Rhinol., 1915, vol. xxx., p. 511.

Intralaryngeal scissors (Fig. 10).—(a) Straight blades; (b) blades curved on the flat; (c) blades curved at right angles; and (d) straight blades with angular shafts. These have been made with small yet very strong blades, and long shafts which are strengthened to prevent strain and consequent weakness in the cutting blades. After the perichondrium with the soft parts have been raised from the inner wall of the larynx by the periosteal elevator these scissors are of great service, for they can be easily manipulated inside the laryngeal cavity without interfering with the view; consequently the entire cutting away and removal of the growth may be performed under direct vision. The straight scissors or those curved on the flat are used in making the upper and lower incision—i.e., above and below the growth—before backwards. The rectangular scissors are used to separate the mass posteriorly from the arytenoid cartilage.

Lack⁹ has described and summarised the difficulties of this operation as mainly due to the fact that "splitting the thyroid cartilage and pulling aside the two halves with retractors gives a very poor view of the interior of the larynx; that with this opening there is great difficulty in manipulating forceps and cutting instruments, also in defining the limits of the growth and removing it thoroughly." He goes on to say that in thyro-fissure to obtain sufficient access it is often necessary to divide the thyrohyoid membrane and "to pull the two halves of the larynx forcibly apart"; in consequence, the patient after the operation may have "difficulty in swallowing." Also, that after thyrotomy there is often "considerable pain for some days," due probably to the "wrenching apart" and "bruising of the tissues" from the prolonged retraction, &c. He therefore suggests that the difficulties are best overcome by resecting a portion of the healthy cartilage underlying the growth in one piece together with the growth.

The chief object, however, of the operation of thyro-fissure is thoroughly to remove the growth with as little destruction of the larynx as will, so far as possible, ensure complete eradication of the disease, while at the same time leaving the patient with a serviceable voice. Since the removal of a large portion of the healthy cartilaginous framework may lead to narrowing and possibly stenosis of the larynx, with consequent impairment of voice, and this is admitted by Lack, it should be our main endeavour to save rather than destroy, compatible with safety, the healthy surrounding parts.

Improvements in technique, consequent on the introduction of more suitable and efficient instruments, have resulted in these difficulties being overcome. The operation of laryngo-fissure as now carried out is greatly simplified, the more thorough removal of the disease can be more easily assured, and the risk to life from so-called recurrence, which usually implies imperfect removal, reduced to a minimum.

The illustrations were drawn for me by Mr. Thornton Shields from special dissections prepared to show the steps of the operation and the advantage of the instruments employed. The instruments are made to my design by Messrs. Mayer and Meltzer, of Great Portland-street, W. The retractor and clamp forceps were originally made for me by Mr. Lewis, of Westmoreland-street, W.

THE LATE SEQUELÆ OF FRAMBOESIA.

By PHILIP HARPER, M.R.C.S., L.R.C.P. LOND.,
DISTRICT MEDICAL OFFICER, RA PROVINCE, FIJI.

Locomotor ataxy, general paralysis of the insane, and aneurysm, well recognised as sequelæ of syphilis, seem to have been generally overlooked as remote results of frambœsia.¹ Reference to Allbutt's "System of Medicine," Castellani's "Manual of Tropical Medicine," and the "Encyclopædia Britannica" fails to find any mention of this relationship. Amongst Fijians syphilis does not at present exist, whilst frambœsia is universal.² We can be sure that the disease which is universal to Fijians is yaws and not syphilis, because of (1) its symptomatology and physical signs, which are different from those of syphilis; (2) the fact that the disease is not hereditary; (3) the therapeutic tests; and (4) the fact that there is not a single absolutely certain case of primary syphilis in a Fijian nor of any hereditary syphilitic manifestations in Fijian infants.

The following are a number of cases of tabes and general paralysis of the insane occurring in one district medical officer's routine practice in a district of 6000 Fijians. Several other but less clear cases were seen. Aneurysm is so common in Fijians, both male and female, that I have not included any accounts here, but it may be of interest to note that my first post-mortem examination in Fiji was on a middle-aged Fijian native minister who died suddenly from an aneurysm that had burst into his pericardium.

With regard to the cases that follow it may fairly be said that the Fijian is a difficult subject to examine for nervous disease, partly owing to the prevalence of physical conditions which are unusual among Europeans. For instance, trachoma, or a disease very similar to it, too often prevents the pupils being seen, whilst the enormously thickened horny sole of a Fijian's foot renders the plantar reflex unobtainable.

CASE 967/15 (tabes).—Vereti, a male Fijian aged 29 years, from the town of Yanuyia, Nadroga province, came to see me on Oct. 26th, 1915, complaining of complete blindness in the right eye and of increasing blindness in the left eye. His illness, he said, had started a year before with fever and headache, and nine months ago he was aware that his sight was definitely going. This had steadily got worse up to the date of his consulting me. He said there was nothing else wrong with him. On examination the urine was normal. His gait was a typical high-stepping motion with a broad base and with a violent stamping down of the heel. There was marked incoördination on standing with eyes closed and feet together. He was unable to stand on one leg. The knee-jerks were absent. After lengthy testing the left pupil was thought to react very sluggishly and very slightly both to light and accommodation. The media of the eye were clear and the discs easily seen.

CASE 478/16 (general paralysis of the insane).—Solomoni, a male Fijian aged 30 years, from Naqiki town, Nasavusavu province, came complaining of pains in the abdomen and legs. The knee-jerks were increased; there was considerable muscular incoördination; the right pupil was large and the left small, neither reacting to light but both reacting to accommodation.

CASE 1047/15 (tabes).—Orea, a male adult Fijian from Masimasi town, Tai Levu province, had double optic atrophy, absence of knee-jerks, inability to stand on one leg. The pupils were small; there was, of course, no reaction to light, but on being told to look into the distance it was considered that the right pupil was enlarged.

CASE 48/16 (tabes).—Paula, male adult Fijian from Vaidoko town, Ra province, had double optic atrophy, absence of knee-jerks, and the left pupil was irregular and smaller than the right. There was no pupillary movement to light or accommodation.

CASE 465/15 (general paralysis of the insane).—Taniela, a male middle-aged Fijian of Naukuloa town, Ra province, came to see me on June 4th, 1915, saying that ten years ago he had been in hospital for backache. He remained in hospital for many months without improvement and then left the hospital and, as he said, recovered. His present illness was described as having started three months before his visit to me with tremor of the fingers and tremulous,

¹ H. A. A. Nicholls (Dominica, W.I.): "In yaws there are no lesions of the nervous system, as in syphilis."—*Twentieth Century Practice*, London, 1899, vol. xvi., p. 332.

² Manson: "Against its [yaws] being syphilis is the practical absence of syphilis among the natives of Fiji, where this form of ulceration is particularly common."—*Tropical Diseases*, fourth edition, London, 1907, p. 576.

⁹ See THE LANCET, 1896, vol. i., p. 1638. Partial Excision of the Thyroid Cartilage as an Alternative to Thyrotomy in Malignant Disease of the Vocal Cords, Proc. Roy. Soc. Med., Laryngol. Sect., 1916, vol. ix., p. 62. Partial Resection or Window Resection of the Larynx for Intrinsic Malignant Disease, Journ. of Laryngol., 1916, vol. xxxi., pp. 121-128.

rather inarticulate, speech. His relatives volunteered the information that he was getting thin and weak, whereas he had previously been an unusually powerful man, and that his disposition had completely changed. He had been an exceptionally trustworthy, well-behaved, Government official of a very religious turn of mind. His disposition was said to be now quite the opposite. On examination speech was found to be tremulous and rather explosive. Although he used to be a lay reader, now when told to say the Lord's Prayer his articulation became quite unintelligible at the Fijian equivalent of "Hallowed be Thy name." The knee-jerks were very much increased; there was a tremor of the fingers which prevented the patient from picking up a pin. He was under my care for three months, during which time his mental condition got rapidly worse. Towards the end of this time his mental condition is shown by the fact that he told me that he was a harbour master (a high office in Fiji), and on another occasion that he was a big landowner and would give me certain very valuable lands which, as a matter of fact, are now owned and worked by Europeans. There was no basis of truth in his statement that he was a harbour master or a landowner. He then one day went to the house of a native medical practitioner during the absence of the latter, and exposed himself indecently to the native doctor's wife and made indecent suggestions to her. He was then sent to the Suva Lunatic Asylum, where he now remains. During the regrettable occurrence which led to his detention in the Suva Lunatic Asylum he was supposed to be in the charge of his brother, named Tiacoro, whose case will be next described.

CASE 678.16 (general paralysis of the insane).—Tiacoro, a middle-aged male Fijian of Nanukuloa town, Ra province, came to see me on August 5th, 1916, with the history that until four months previously he was quite well. At that time he went to see Taniela (the patient in the previous case) at the lunatic asylum. Whilst in Suva he had, he says, filarial fever (he is subject to attacks of filarial fever and has elephantiasis of arm, leg, and scrotum). He was in Suva only a week or two on this occasion, and on returning to Ra he was weak and depressed. This weakness increased, until on August 3rd he was discovered by a native medical practitioner, Tomasi Mawi, at 3 A.M. wandering away in the bush "looking for Taniela," as he said. On examination he was found to be very much thinner than he was last year when I examined him. His face was bloated and expressionless, a great change from his alert, vivacious expression of a year ago. Articulation was hesitating and difficult, but correct. He had a fine tremor of his fingers, which made him very clumsy. The knee-jerks were very much increased: the pupils were small, equal, and sluggish in their reaction to accommodation and there was absolutely no reaction to light. The sight was not affected.

It will follow from the above cases that there is a very high rate of such nervous disease amongst the Fijians, but it must be remembered that the whole Fijian population has been infected with yaws, and probably the case-rate following yaws might not greatly differ from the case-rate following syphilis.

Fiji.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

WOUND OF THE PORTAL VEIN; OPERATION; DEATH NINE DAYS LATER.

BY W. H. C. ROMANIS, M.B. CANTAB., F.R.C.S. ENG.,
TEMPORARY LIEUTENANT, ROYAL ARMY MEDICAL CORPS.

THE following case of shell wound of the abdomen, which was treated in a casualty clearing station, may be of interest not only on account of the actual injuries caused but also as an instance of a shell fragment passing through the abdomen from front to back without injuring any portion of the intestinal canal.

An Australian soldier was wounded by high-explosive shell at 4 A.M. on July 5th, the fragment entering just below the left costal margin, one inch to the left of the ensiform cartilage. When first seen late the same evening the patient's condition was bad; he was pale and cold, with a thready pulse of 120, vomiting was marked and the abdomen was very rigid all over, tenderness being especially marked in the epigastric region. Under chloroform a laparotomy was performed through the left rectus at 3 A.M. on the 6th, 23 hours after the wound, and the abdomen was found to contain a large quantity of fresh

blood. A track was traced down and to the right through the left lobe of the liver, emerging on its under surface, passing through the lesser omentum and tearing a lateral hole about half an inch long in the portal vein, from which blood was gushing freely. A plug was placed in the liver wound and two artery forceps were clamped on the side of the vein in a longitudinal direction, thus controlling the hæmorrhage. The track of the missile was then seen to pass on just to the outer side of the second part of the duodenum and to pierce the peritoneum of the posterior abdominal wall here. Owing to the condition of the patient the fragment was followed no farther, and a rapid examination of the stomach, small intestine, and transverse colon discovered no perforation. The blood was then mopped out and the wound closed in three layers in the usual way, the plug and artery forceps being left *in situ* with their handles emerging from the upper end of the incision, half an inch of which was left unsutured for that purpose. Next day the patient was much better, with no vomiting, and he continued to improve for several days; the plug was removed on the second day and the artery forceps taken off on the third day without any difficulty. Improvement continued till the eighth day, when the patient was doing well and eating solid food, his bowels being opened naturally each day. On the evening of the eighth day, however, he suddenly complained of severe hypogastric pain, vomited twice, and passed some urine with much blood in it. His abdomen remained quite soft and mobile, but his pulse failed and he died in an hour.

Post mortem there was no peritonitis, no adhesions, and no perforation of the intestinal tract. The lumen of the portal vein was patent, the wound in it being represented by a sound scar, and the liver substance appeared quite normal. A large retroperitoneal hæmorrhage was present round the right kidney, and on dissecting out the right renal artery an ulcerated hole half an inch long was found on its posterior aspect, close to which there lay a small jagged piece of shell-case, a little larger than a green pea. The patient thus apparently died from secondary hæmorrhage from the renal artery on the eighth day.

Several other instances have been recorded in the present war of cases in which artery forceps have temporarily been left on the large veins of the abdomen, and the above case is only published as one of an uncommon class.

CASE OF TONSILLITIS WITH HÆMORRHAGIC ADENITIS.

BY C. FREDERICK STRANGE, M.R.C.S.,
L.R.C.P. LOND.,

TEMPORARY CAPTAIN, R.A.M.C.; EMERGENCY SURGEON, CONNAUGHT HOSPITAL, ALDERSHOT.

IN the following case of tonsillitis the unusual complication of hæmorrhagic adenitis occurred.

The patient, aged 22, of good physique, R.A.M.C. orderly, was admitted to the Connaught Hospital, Aldershot, on June 27th, 1916, with acute tonsillitis. He had had an attack of tonsillitis last year when at Malta, but never any other illness. His present attack, which commenced the day before admission, came on suddenly while on parade with shivering and chilliness, headache, and sore-throat. The headache was so severe as to prevent sleep. On admission he complained principally of sore-throat. On examination the pharynx was red and inflamed, but there was no swelling of the tonsil and no follicles. Temperature 102° to 103.6° F.

On June 29th our medical specialist, Captain A. Abrahams, asked me to see the patient with a view to surgical interference, as during the past two days a large swelling on the right side of the neck had appeared. I considered this advisable, and the patient was transferred to a surgical ward. Temperature 103°, pulse rapid, respiration not affected. The patient looked very ill indeed. A large glandular swelling occupied the whole of the anterior superior triangle of the neck on the right side, extending from the angle of the jaw to beyond the posterior border of the sterno-mastoid. The swelling was very painful and tender to the touch. There was no fluctuation nor pitting of the skin on pressure. The right tonsil was much enlarged, covered with follicles, red and tender. He could only swallow liquid food with difficulty.

Operation on June 30th under general anaesthesia. An incision 2 inches long was made over the most prominent part of the swelling and a large gland (the size of a pigeon's egg) was exposed. The gland was steadied with forceps and an incision made through the whole of its substance. I had thought that perhaps there might be a gland commencing to break down with pus formation at the centre, but no pus was present. Countless minute hæmorrhages had taken place into all the substance of the gland and the enlargement was entirely due to these hæmorrhages. The gland was left alone. The lower part of the wound was closed with

silkworm-gut sutures, the upper part being left open. No drainage-tube was inserted, the wound being dressed with sterile gauze.

The immediate effects of the operation were most striking. The next day the temperature had fallen to normal, and remained normal till the patient's discharge from hospital. His general condition underwent a sudden transformation. A day previously he was obviously very ill, his facies resembling that of an acute abdominal condition. He could take no food and did not want any. The next day his face was bright and smiling, he had no ill feeling, and his appetite rapidly returned. The wound healed without any suppuration; it was dressed daily with dry sterile gauze, no lotions being applied. The swelling of the neck rapidly disappeared, as also that of the right tonsil, and the follicular condition healed rapidly. In a fortnight the wound was healed, the swelling gone, the throat normal, and the patient was discharged fit for duty.

I am much indebted to Colonel W. Turner, officer in charge, Connaught Hospital, Aldershot, for his permission to publish the above.

Medical Societies.

MEDICAL SOCIETY OF LONDON.

John Ward and His Diary.

THE proceedings of this society were reopened on Oct. 9th, by Lieutenant-Colonel D'ARCY POWER, the President, who read a paper entitled "John Ward and His Diary."

The diary, which consists of 16 volumes of manuscript, and the writing of which was cramped, smudged, and very difficult to decipher, had not hitherto received the study it merited. It was not written in diary form, but contained an irregularly arranged collection of notes, extracts, anecdotes, and observations, which threw much light on the manners of the period and on the lives of individuals otherwise known only by names. Its author, the Rev. John Ward, who was born in 1629, and died in 1681, was in residence at Oxford in the stirring times before the Restoration. He was thus a contemporary with the founders of the Royal Society, and his diary gives an insight into university life at a time when a new interest was being taken in natural science. He left Oxford in 1660, probably because of the changed order of things which followed on the Restoration, and at first seemed to be in doubt as to selecting his profession, whether to choose that of medicine or the Church, for he took Holy Orders and at the same time attended lectures on anatomy in London. Finally he became vicar of Stratford-on-Avon. The paper is given in full in the present issue of THE LANCET.

MEDICO-PSYCHOLOGICAL ASSOCIATION.

"Séguin and his Work."

A MEETING of the South-Eastern branch of this association was held at the Medical Society's rooms on Oct. 4th, the chair being occupied by Dr. DAVID BOWER.

Dr. G. E. SHUTTLEWORTH read an interesting paper on "Séguin and his Work." He considered that Séguin, with whom he had been personally acquainted, could be designated the pioneer in the training of backward children and in the advocacy of the educational principles which were essential to their development. That master anticipated many of the modern methods which had since been accepted by the educational world as recent discoveries: his acute foresight placed him in advance of his times, for his contentions were derided by the educationists of his day. When only 27 years of age he opened a school for idiots in Paris, the first of its kind of which there was any record. It became a success, and later formed the model for similar institutions in Switzerland, Germany, America, and this country. The French Government issued a very favourable report on his work. In 1866 appeared his book entitled "Idiocy and its Treatment by the Physiological Method." In this he claims that his methods were also applicable to ordinary children. Man being primarily an animal, the predominant means of education must be through his animal activity and virility and through his senses. To attain to his best in higher spheres he must also be the best sort of animal possible—i.e., all the physical functions must be cultivated.

Attention must be devoted to the physiological development of the senses before any effort is made to educate the mind, experience, not memory, being the mother of ideas. Séguin was also a great advocate of open-air schools, an idea he developed a great deal in New York; and he devised finger-drill and sensorial exercises, which had been modified and perpetuated by Madame Montessori. Séguin laid great stress on gaining the child's confidence and love, and was a great believer in religion and other spiritual agencies, his teaching appearing to centre around the precept: "To make the child feel that he is loved, and to make him eager to love in his turn, is the end of our teaching, as it has been the beginning."

Dr. R. ARMSTRONG-JONES, in discussing the paper, agreed as to the great power of spiritual influences in the education of defectives, and he had often been agreeably surprised at the success which a chaplain attained by means of the singing of hymns and simple religious precepts, and this special branch of medicine was much indebted to Séguin, who pointed out its value.

Dr. A. HUME GRIFFITH (Lingfield) spoke of the great help which Séguin's teaching had proved in a colony of epileptic children with which he was connected, where open-air schools were extraordinarily beneficial. The endeavour to give the pupils ambidexterity had produced a greatly improved general mentality. In this work, which required infinite love, tact, and patience, religious teaching produced a remarkably good effect.

Dr. BOWER, Sir GEORGE SAVAGE, and Dr. FLETCHER BEACH also spoke, and Dr. SHUTTLEWORTH replied.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—

An ordinary meeting of this society was held on Oct. 6th at the society's rooms.—The retiring President, Dr. Leonard Dobson, inducted his successor, Dr. Arthur Saunders.—The new President presented to Dr. Dobson the Keetley medal, and congratulated him on the success of his year of office. Dr. Saunders then delivered his Presidential address on "Some Aspects of the Throat and Naso-pharynx in their Relation to General Medicine." After recapitulating the chief varieties of naso-pharyngeal infections, he dwelt particularly on modern bacteriological developments as aids to diagnosis, and discussed at length the treatment of tonsils and adenoids and their bearing, when diseased, on other organs and on the general condition.—A vote of thanks, proposed by Dr. A. J. Rice Oxley and seconded by Dr. G. B. Shuter, was carried unanimously. There was a large attendance of members and visitors.

Reviews and Notices of Books.

Elements of Folk Psychology: Outlines of a Psychological History of the Development of Mankind.

By WILHELM WUNDT. Authorised translation by EDWARD LEROY SCHAUB, Professor of Philosophy in Northwestern University. London: George Allen and Unwin, Limited; New York: The Macmillan Company. 1916. Pp. 532. Price 15s. net.

Professor Wilhelm Wundt, professor of psychology in the University of Leipzig, is one of the greatest contemporary masters of his subject, and has been responsible for more activity in the prosecution of psychological study on its philosophical side than any other modern teacher. His industry and his range of accomplishments are alike wonderful, and these outlines of a psychological history of the development of mankind display the solid learning which lies behind what is stated by the author to be a sketch.

The subject of folk psychology is dealt with in this book in four sections. The first, which has relation to primitive man, includes a discussion of the organisation of man into society, and in it we have described the beginnings of language and of art and the earliest beliefs in magic and demons. It is in the indefinite concepts of religion, which fall under the head of demon worship, that the earliest rising of the medical idea took place, the original duties of the medical man (commonly, of course, also the magic man or the priest) being to provide charms to ward off the sickness inflicted by evil spirits. The second section of the

book deals with what Professor Wundt calls the totemic age, and we have read no better introduction to the study of such difficult subjects as totemic culture, the origins of exogamy, the various systems of polygamy, the laws of taboo, and the origin of the fetish cult and of ancestor worship. Those who have read Sir George Frazer's monumental "Golden Bough" well know how extremely difficult it is to form any definite opinion on such matters, for example, as totemism and exogamy. What evidence can be collected, or what can withstand criticism, supports no one theory, and we are left to gather from Professor Wundt that a good deal of research may be required to assist our advances. In the third section we are at the age of heroes and gods. We have reached a period when the family has become organised, when classes have become differentiated, when the ideas of a legal system have become expressed in penal laws, and when states have been founded and ruled according to definite principles. The last section is entitled "Development to Humanity," and the author's views on world empires, world culture, and world religion are wise, dispassionate, and at variance with those which have been put forward in recent years by some of his prominent countrymen.

Professor Wundt, in this elementary though learned treatise, has studied the phenomena of his subject so far as possible synthetically, accepting the common conditions and their reciprocal relations. But in doing this, he points out that he has not given the various facts a proportionate degree of attention for reasons which are absolutely sound. In the case of the better known phenomena it has been found sufficient to sketch their place in the general development, while when dealing with those which are less familiar more detailed discussion is required. Hence the forms of original tribal organisation and of the consummation of marriage, demon and totem cults, and various features of primitive culture are dealt with at some length, while the social movements that reach over into historical times, such as the founding of states and cities, the origin of legal systems, and the like, are described in outline only. We recommend the book cordially to our readers.

Collected Papers on Analytical Psychology.

By O. G. JUNG, M.D., LL.D., formerly of the University of Zürich. Authorised translation edited by CONSTANCE E. LONG, M.D. BRUX. With 14 figures. London: Baillière, Tindall, and Cox. 1916. Pp. 410. Price 12s. 6d. net.

THESE papers are a misnamed medley of nebulous dreamings. They do not treat of psychology, nor are they analytical. Any careful reader of the preface to the book will certainly agree with the author that there is "no scientific justification" for the procedure of the Zürich School of Psycho-analysis, of which he is father and prophet. Dr. Jung argues that since present-day science is based as a whole upon causality, the study of psychology "cannot be exhausted by causal methods only, because the mind lives by aims as well." He paraphrases this odd dictum by saying that "the method of the Zürich school is not only analytical and causal, but also synthetic and prospective, in recognition that the human mind is characterised by *causæ* and also by *fines*." (It is difficult to see any extra light from the employment of Latin terms.) He, moreover, uses the word "Psychology" as identical in content with the *psycho-analysis* now in vogue with a certain group of psychiatrists or mind-healers, for he proceeds to say that there are "two types of psychology, the one (the Freudian) following the principle of hedonism, the other following the principle of power. Scientific materialism is pertinent to the former type, the philosophy of Nietzsche to the latter"

In further justification, or attempt at explanation, of one of his main objects, which is to show why he differs from Freud's teaching, the author tells his readers that there is "a vital necessity" for his hypothesis because it is impossible to live according to the intimations of infantile hedonism (as implied in Freudism); and he contends that if Freud's conception is to be retained, it must be taken symbolically! "Symbols," he says, "are necessary for the moral education of mankind. 'Concrete values' cannot take their place. The further development of mankind can only be brought about by means of symbols which represent something far in advance of himself, and whose intellectual meanings cannot yet be grasped entirely. The individual

unconscious produces such symbols and they are of the greatest possible value in the moral development of the personality."

The preface ends thus:—"This brief résumé may show what the reader cannot find in this collection of papers. The essays are stations on the way of the more general views developed above." It appears to us that this pregnant preface, as well as the editor's preface, which should not be passed over, very clearly shows what any reader would certainly find in the papers; and might even aid him materially in his decision as to reading further. He would find, as the present writer, who has studied them all, has found, many bare assumptions and arguments based on deductions untested by any critical appeal to further relevant observations. Psychology (the study of which to all except the present-day psycho-analysts who are disciples either of Dr. Freud or Dr. Jung, means an effort to explain the phenomena of consciousness) seems to mean, at least to Dr. Jung, the study of what he calls "the unconscious"—a term which is spelt with a capital "U" by many psycho-analysts, including the editor of the volume before us. This "unconscious" he defines as the sum of all those psychological events which are not apperceived, and so are unconscious! To this purely hypothetical entity, intruding into a person's "consciousness," he attributes the "neuroses" generally, which result, according to the new "psychology," from internal battles between the two powers. And on grounds such as these he builds up his "constructive" theory and founds his practice, which, in spite of his contentions, is much the same as that of all who call themselves "psycho-analysts," of whatever school they may be. In practice psycho-analysis seems to consist in a search for what is called the individual patient's "libido," which, although interpreted by Dr. Jung or his followers as "the instinctive psychological effort," the "élan vital," the "joy of living," or the "fundamental interest of the individual," is found by the practitioner to be in nearly all, if not all, cases, as in the instances cited in these papers, reducible to sexual desire.

Now it need not be argued that the influence of the sexual system on the organism has long been recognised as playing a very important part in the development of so-called neurotic disturbances, especially in civilised or highly socialised humans necessarily subject to economical and moral restraints; nor, indeed, is this fact ignored by any careful medical observer whose task it is to investigate and treat cases of mental or nervous disorder. But it is certainly not true that all cases of nervous disorder, called "functional" because the physician would not expect to find any actually demonstrable morbid condition of the nervous system if he could observe it in its working, are in any sense, however subtle, reducible to sexual disturbance, recognised or unrecognised by the patient. And with regard to such cases as may be correctly referable to unrecognised or imperfectly remembered physiological impressions affecting the sexual system, there is surely no light thrown on them by hypothesising the chimera of Unconscious Mind, and imagining an unconscious *mental* process conflicting with consciousness. Dr. Jung appears to be a spiritualist who will have no truck with those who speak of brain action apart from consciousness. He ridicules indeed, and deems as antiquated, the very notion that delusions and other mental disturbances can be provoked by morbid processes of any kind in the brain cells, arguing that such disorders occur in "certain functional disturbances," and even in normal people! "To seek to ascribe," he says, "symptoms of that nature directly to disease of the brain cells I hold to be superficial and unwarranted." This is surely a striking example of the confessedly unscientific attitude of the author; and justifies a strong suspicion that his knowledge or his memory of the facts of cerebral physiology and pathology is sadly inadequate.

To sum up, this book alone should go far towards proving to doubting readers that the theory of present-day "psycho-analysis" as set forth even by the anti-Freudian school, is the offspring of mysticism and unbridled phantasy, and that its practice, to say the least, is calculated to be very dangerous. The perusal of Chapter IX., on "Some Crucial Points in Psycho-analysis," should not be omitted by those who wish to form their own judgment on this conclusion. The editor and translator of this book, however, in calling attention to its issue in the second year

of the great European War, says: "We need a new philosophy of life to take the place of that which has perished in the general cataclysm, and it is because I see in the analytical psychology which grows out of a scientific study of the Unconscious the germs of a new construction that I have gathered the following essays together." Surely this disciple claims more than her master in pronouncing these papers to be "scientific."

New Inventions.

A STRETCHER FOR TRENCH USE.

THIS stretcher has been devised so that angles may be negotiated with the minimum of discomfort to the wounded man when being removed from the trenches. The stretcher when open, prepared for a patient lying full length, is the same width as the Furley stretcher with canvas bed of the same length (St. John Ambulance Association pattern). The importance of keeping fractured lower limbs perfectly at rest in the horizontal position will be acknowledged, but it is not possible to carry a full-length stretcher horizontally through narrow trenches with sharp turns. By flexing this stretcher at the point shown, the trunk only of a patient is disturbed and trench traverses can be negotiated without discomfort. The stretcher has been successfully carried along a trench with a minimum width of 26 inches and a maximum of 42 inches with a number of traverses at various angles. With the traverse bars slightly collapsed it will pass through a trench 21 inches wide. Once clear of sharp angles the stretcher may be restored to the horizontal position in a moment and can then be carried in the usual way.

The stretcher has obvious uses apart from trench warfare wherever narrow staircases, corridors, or sharp turns are met with. The poles are of ash, 7 ft. 1 in. long, and each is provided with a hinge about the centre of its length. The hinge is of an aluminium alloy, and is so designed that it can be held securely and rigidly by a steel pin when in a horizontal position or when flexed at a definite angle. The foot ends of the poles are provided with handles which can be

FIG. 1.

The patient is sitting on the stretcher, the head end of which has been raised, and he is bandaged for a fracture of the leg. The back is held rigidly in position by steel pins. The length of the stretcher in this position is 5 ft. 6½ in. over all. The patient is being lifted by bearers wearing Cantile pattern slings to distribute the weight over their shoulders. The bearer at head is grasping the runners. It will be observed that the canvas does not sag under the patient.

FIG. 2.

Shows the stretcher and patient in the same position as in Fig. 1, being carried along a narrow trench. The bearer at the foot-end of the stretcher is standing aside, the handles being turned inwards, when the over-all length of the stretcher is 5 ft.

used in the ordinary manner or can be folded inwards parallel with the end of the canvas and permit a bearer to grip them around the traverse when he is facing the patient's feet, thus shortening the stretcher and protecting the bearer's knuckles from the trench sides. There are three traverse bars of St. John Ambulance Association pattern. One is at the foot end in the position usual on a Furley; one is a few inches from the hinge towards the head, and the third about midway between this and the head end of the poles. This type of traverse has been adopted, as it has no tendency to loosen and thus collapse the canvas.

The runners are of aluminium of pedestal pattern, each fitted with a small wooden roller, and are so shaped that they are comfortable to the hand when grasped as handles. In order to obtain great rigidity when thus used the head of each runner encircles the pole and is driven on and screwed fast.

The weight of the stretcher is 19½ lb.—several pounds lighter than the Furley or the R.A.M.C. stretcher. It has successfully withstood severe tests of its strength in both positions.

The stretcher has been produced by Mr. H. Langley Jones, 25, Ailsa-road, West-cliff, at the suggestion of the Rev. H. C. Hutchings, who was then acting as a stretcher-bearer in France, and of Messrs. G. Davenport and Co., Limited, and has been made by Messrs. R. Hoe and Co., Limited, London.

THE LANCET.

LONDON: SATURDAY, OCTOBER 14, 1916.

The Examination of Recruits for Affections of the Heart.

ONE of the most difficult problems in connexion with the examination of recruits is the exact estimation of the condition of the heart. If the heart is of the normal size, the sounds clear, and the rhythm regular, a satisfactory conclusion can be arrived at promptly; but if a murmur is heard, or there is irregularity of the beat, then skill and experience are required in order to distinguish between functional and organic conditions. The main point is to estimate, if possible, the amount of cardiac reserve power; but this is not the only matter for consideration, and, quite rightly, cases in which doubt arises are now referred to experts for opinion.

Since last February, by the direction of the Medical Department of the War Office, recruits in the London district whose rejection was contemplated on account of the state of their heart have been sent to the National Hospital for Diseases of the Heart for examination and report. As up to now over 4000 cases have been dealt with, it will be of interest to explain the general idea underlying the scheme. All recruits are seen in the first instance by a recruiting Medical Board, and those whose hearts are manifestly defective, as shown by the ordinary methods of clinical examination, are rejected or placed in the categories for which they are suitable, while those with obviously healthy hearts are passed. It is only when real doubt arises as to whether a recruit's heart is defective, or how far an observed defect is likely to impair efficiency for military purposes, that the man is sent to the Heart Hospital and subjected to a searching examination with the aid of instrumental appliances, which could not possibly be available for employment by the recruiting boards without the assistance of some such institution. After consideration of the various points and consultation with recognised authorities, a scheme of examination was decided upon at the Heart Hospital which experience has shown to be very efficient in elucidating the problems which present themselves. Every recruit is asked to state what, if anything, he complains of, and a record is made of this, together with a detailed history of his previous diseases and habits. Any subjective symptoms which may be present are inquired into in detail and recorded. He is then given a standard piece of work to do, the pulse, respiration, and blood pressure being recorded before, immediately after, and three minutes after. The urine is analysed, and an electrocardiogram is taken. In a very large proportion of the cases the

heart and chest are also examined by the X rays. Furnished with these data, the physicians proceed to make a thorough clinical investigation under the usual heads of inspection, palpation, percussion, and auscultation. A diagnosis is arrived at, after taking into consideration all the evidence, and an opinion is expressed as to which category of military service, so far as his heart is concerned, the recruit is to be placed under. Here the most practical point for consideration is that, although a man with a slight cardiac lesion may support well the strains of civil life, when he can stop work at will, he may not be found suitable for military service, in which he must "carry on" or become a casualty. A copy of the paper containing all the data, as well as the diagnosis and opinion, is transmitted to the Medical Board sending the recruit, with whom, of course, the final decision rests.

That the practised medical examiners who constitute the recruiting boards of London should have felt the desirability of having as many as between 4000 and 5000 cases examined in this detailed manner before arriving at a decision is perhaps one of the most striking pieces of evidence that could be adduced of the progress that this department of medicine has made during the last few years, and of the importance attached to the modern instrumental aids to diagnosis. Of 1000 cases examined 447 have been classified as fit for full military service either at home or abroad, 291 as fit for garrison duty or labour purposes, and 262 as fit only for clerical work or totally rejected. These figures are of high significance; they tend to show that many men who at the first examination did not seem fitted for military service, on further investigation were passed for some form of military work, the proportion that were classified as fit for full service being high.

A Campaign against Adult Mortality.

Dr. CHARLES F. BOLDUAN, Director of the Bureau of Public Health Education in New York, has recently stated¹ that most of the health work of late years has been directed to the saving of infant and child lives, while practically nothing has been done to prolong adult life. He illustrates this statement by a comparison of the New York life-tables of the two triennia 1879-81 and 1909-11. The comparison shows that whereas in New York the expectation of life at birth is now about ten years greater than it was a quarter of a century ago, the adult of 40 years or over has actually a shorter expectation than formerly, the decrease amounting to a year or more, according to the exact age-period. Dr. BOLDUAN finds that this condition is not confined to New York City, but applies also to the whole of the United States registration area. The death-rate per 1000 at the age-period 45 to 54 has increased by nearly 2 per cent. during the last ten years, and

¹ Monthly Bulletin of the Department of Health of the City of New York, vol. vi., No. 4.

at the next older decennium by nearly 7 per cent. He regards the solution of the problem as a matter of the greatest importance, middle age being the period at which the addition of years of life would be of most value to the race. Similar considerations have evidently weighed in the appointment by the Department of Trade and Customs of the Commonwealth of Australia of a committee appointed to inquire into the causes of death and invalidity in the Commonwealth and have resulted in a special report, which has just appeared on the risks of middle age² and on the chances which cut off thousands of people in their full maturity.

The causes of the risks of middle age are carefully discussed by the Australian Committee, and in a single paragraph they give without hesitation an answer to the question as to their origin. Everything, they say, which involves overstrain, everything which favours chronic poisoning of the blood with alimentary toxins or with products of tissue change, everything which encourages infection of the blood from bowel or throat must count among the causes of excessive blood tension. And in high blood tension they see the principal risk of middle age. Put shortly, accumulating wastes and unreasonable strain are the determining factors. The report draws a picture of the man who has had an active school career, with devotion to athletics, followed by a hard struggle for success in some handicraft or profession, who still taxes to the utmost his nerve and muscle, who still pursues, it may be, some vigorous athletic sport, and who takes food rapidly and in large quantity, with soup and meat forming a substantial part of his diet. The picture is one not unfamiliar in the mother country. The report goes on to call attention to the high rate of death from apoplexy as well as from pneumonia and pericarditis, which are in Australia very deadly for patients with high tension. The dangers of the period of failing tension are dwelt upon, when the persistent strain has much tried the heart, and when, if the patient is not carried off by apoplexy or some intercurrent inflammation or infection, signs of heart failure become dominant. In hospital practice in Australia at least two-thirds of the deaths attributed to organic heart disease are considered a sequel of raised tension. Due credit is given in the report to the effects of alcohol, syphilis, and gout as adjuvant causes of the risks of middle age, but stress and diet are allotted their place as the primary agents. Dr. BOLDUAN, out of a wide familiarity with the conditions in the United States, deals with the same etiological factors. The rush of modern city life has been credited, especially in America, with the increased death-rate from cardiac and arterial disease, but he finds that the rural districts show precisely the same tendency. Exposure, strain, and occupational injury are factors which are common to all classes and countries, and while alcohol, syphilis, and other chronic poisonings must take their share of the blame, stress and

over-eating, especially over-eating of protein, are those on which in America, as in Australia, suspicion rests most heavily.

To combat this high adult mortality, Dr. BOLDUAN suggests an organised campaign, and he gives an outline of a plan of education for the control of diseases of the heart, kidneys, and arteries. At the outset he thinks nothing would be more effective than a large exhibition of adult hygiene on the lines of an exhibition held at Dresden a few years ago. He would keep public opinion aroused by constantly reiterating the statement in the press and elsewhere that persons over 40 do not live as long as they did 30 years ago—an assumption on which vital statistics should have some critical things to say. He would organise boards of sanitary control to watch over the health of employees, putting the responsibility for the sanitary conditions of any industry upon the industry itself. He points to the good example of the New York Department of Health, which has placed the services of a highly trained medical examiner at the call of all its employees. A complete medical examination can be obtained by them free of charge, and the information turned to good purpose in detecting the onset of degenerative disease at the earliest stage, when treatment is still hopeful of result. In the next rank of importance he places an extension of work directed against the venereal diseases. The Australian Committee begins further back with its proposals, and suggests an extension of the medical inspection of schools, and an increase of school instruction in personal hygiene. This is to be followed by an inquiry into the undue prevalence of high tension in certain occupations and by the provision of facilities for the early diagnosis and treatment of high tension. The Australian Committee proposes concretely that provision be made for industrial workers not to return to arduous work after serious illness until time has been allowed for proper convalescence; and that some system of oversight of the health of industrial workers should be instituted, correlated with the provision, when necessary, of temporary relief by some scheme of insurance. These proposals are in a line with those recently made by Professor W. J. ASHLEY in an introductory address at Birmingham University.

The evils alluded to in both the reports are very wide, and the remedies suggested, though comprehensive, seem somewhat vague. But the idea of a campaign against avoidable adult mortality is one which has much to commend itself to thoughtful people; and it need not become an opportunity for the exhibition of rampant faddiness, though risk lies in this direction. The further development of the schemes will be watched in this country with keen interest by our medical men, sanitarians, and statisticians.

FATAL CASE OF ANTHRAX.—At an inquest held at Mossley, Yorkshire, on Oct. 4th, on a Congregational minister of that town it was stated that deceased had purchased a shaving brush while on a holiday at Blackpool and the medical evidence showed that anthrax was due to the use of this brush.

Annotations.

"No quid nimis."

A CURVE OF WORKING EFFICIENCY.

MOST of us are aware that we do not begin our work in the morning at full efficiency, and that some time may elapse after the commencement of the working day before the maximum speed of output is reached. At the end of the working period a corresponding tailing off may be less readily observed. Exact observations on this interesting subject have been made by Dr. H. M. Vernon in regard to the output at munition works, and published as an appendix to Memorandum No. 5 by the Health of Munition Workers Committee. In works where the motive power is electric, and the amount supplied to each section is registered by a separate watt-meter, the rate of starting and stopping work can readily be ascertained by means of these power records. Dr. Vernon found that in a large shell shop which turned out 30,000 3-inch shrapnel shells per week, the power supplied began to mount up two minutes after starting time, and reached half its full value in four minutes; while the power supplied to a section of 200 women turning fuze bodies did not begin to rise till five minutes after starting time, and did not attain half its maximum value until six minutes later. In other words, the women operatives wasted about seven minutes more in starting than did the operatives in the shell shop, most of whom were men. On the other hand, the fuze-turners finished more strongly than the shell shop operatives, and it was found that both sets of operatives lost, on an average, about the same aggregate of time in starting and finishing during the course of the whole day—viz., 34 minutes. There was no inherent reason why work should have been started promptly in one shop and not in the other. Dr. Vernon considers there can be no necessity for the waste even of this amount of time in starting and finishing work, and that 10 or 15 minutes should be an ample allowance. The 20 minutes thereby saved could then be deducted from working hours without any reduction of output. The matter is of practical importance because, although stern necessity may compel long hours of labour on the part of many munition workers, it is evident that the shorter the times for which they are shut up in the factories the better their chances of health and happiness. At one large block of works the manager makes a point of going into the various shops at starting time and seeing that the operatives begin work promptly. In this way he found that a considerable amount of time was saved. Concentration at work has for a corollary longer hours at play, and is clearly shown by the memorandum to be a factor making for health.

SICKNESS BENEFIT AND VENEREAL DISEASES.

ONE serious obstacle in the way of early recognition of venereal disease and of its efficient diagnosis and treatment is now likely to be removed. At the present time venereal disease comes under the clause in the Insurance Act under which benefit is not given when illness is caused by wilful misconduct. The National Conference of Friendly Societies recently held in Liverpool was addressed by Dr. Otto May on behalf

of the National Council for Combating Venereal Diseases, who put the case very forcibly for the granting of sickness benefit by Friendly Societies, trades unions, and others to their members who were known to be suffering from venereal disease; to place, in fact, venereal disease in the same position as other infectious diseases as regards their treatment. Dr. May's address was well received, and a resolution was carried:—

That this executive committee of the National Conference of Friendly Societies, having seriously considered the report of the Royal Commission on Venereal Diseases and the several recommendations made therein, is of opinion that such vital national and domestic interests are involved that it is desirable, with a view to the effective treatment and possible ultimate extermination of such diseases, that societies should consider the advisability of revising their rules in such a manner that members shall not be deprived of sickness benefits by reason of their suffering from any such disease.

Besides this academic resolution, which might or might not carry force among the constituent Friendly Societies, a definite rule was suggested for adoption by Approved Societies pending the proposed amendment of the National Insurance Act. The rule is as follows:—

An insured member shall not be entitled to sickness or disablement benefit in respect of an illness or accident caused by his or her serious or wilful misconduct, provided that a member shall not be deprived of sickness or disablement benefit if incapable of work through venereal disease.

This action of the Friendly Societies is another welcome indication of the change of attitude among the public at large towards the treatment of venereal diseases, and increases the hope of a really efficient campaign in the future. This hope is fortified by the fact that the London County Council propose to carry into immediate effect the recommendations of the Royal Commission.

THE BRITISH JOURNAL OF OPHTHALMOLOGY.

IN 1857 a journal of ophthalmology was started by the staff of the Moorfields Eye Hospital under the title "*The Royal London Ophthalmic Hospital Reports*." The title was at that time somewhat misleading, for although the contributors consisted entirely of Moorfields surgeons and students, the periodical contained abstracts of the ophthalmic literature of foreign countries and other matter of cognate interest. This periscope of abstracts was discontinued after 1864, and perhaps partly owing to the lack of any such convenient source of information, the *Ophthalmic Review* was inaugurated in 1882. It differed from the *Reports* in being open to all comers for original communications, whilst specialising in short reviews of current literature. These two were the only British journals devoted to ophthalmology, and apart from the *Transactions of the Ophthalmological Society*, started in 1881, were the only medium for the contribution of articles specifically to ophthalmic surgeons until 1903, when Mr. Sydney Stephenson commenced the publication of the *Ophthalmoscope*. Thenceforth, until the present time, all three journals have continued to appear. At the outbreak of the European war in 1914 it was felt by many that British ophthalmologists should draw together and unite in issuing a single journal which would be more thoroughly representative of British ophthalmology. Indications were not wanting that such a scheme would meet with the approval and support of their colleagues in neutral and allied countries, and, indeed, one of the strongest supporters and even initiators of the idea was the late Professor Straub,

of Amsterdam. Hence it was that in July of this year the President of the Ophthalmological Society of the United Kingdom, Mr. Walter H. H. Jessop, called a meeting to consider the matter. Attendance at the meeting was necessarily by invitation, but the greatest care was taken by Mr. Jessop, in consultation with other prominent ophthalmologists, to ensure that the gathering should be thoroughly representative of all parts of the British Islands. The result was that negotiations were set on foot to incorporate the three existing journals in a new journal, to be called *The British Journal of Ophthalmology*. These negotiations proved most successful, and in order to carry out the scheme a meeting, to which all British ophthalmologists were invited to attend, was held at the Royal Society of Medicine on Sept. 20th. At this meeting a limited liability company was formed, and so far as the financial arrangements are concerned the success of the venture is already fully assured. It is proposed to commence the publication of the new journal in January, 1917, and from that date the *Royal London Ophthalmic Hospital Reports*, the *Ophthalmic Review*, and the *Ophthalmoscope* will cease to appear. The new journal will be edited, under the supervision of an editorial committee, by Mr. Stephenson, with the help of an assistant editor. There are obvious reasons why a period of national upheaval may appear ill-fitted for undertaking new responsibilities, but such reasons under close examination will not prove so cogent as their *prima facie* appearance warranted. Though individuals perish, the national life flows on and will continue to flow. The effects of to-day are the causes of to-morrow, and thus we, the inheritors of the past, are the guardians of the future. A revolution is a great opportunity for progress, and we feel assured that the ophthalmic surgeons of our nation, limited though their special sphere may be, are rightly actuated in thus making a bold effort to strengthen the foundations upon which they and their successors may the more firmly build.

SYMPTOMS PRODUCED BY JACKSON'S PARIETO-COLIC MEMBRANE.

THE part played by bands or adhesions in the causation of abdominal symptoms is still unsettled. In the *Medical Journal of Australia* Mr. C. E. Corlette has reported the following case which is important, as the symptoms were definitely shown to be due to Jackson's membrane. A girl, aged 19 years, was seen for severe pain in the right side of the abdomen. The attack had lasted for two days, but for the past six years or more the patient had pain in the same situation almost constantly. At various times acute exacerbations occurred. These attacks lasted several days, and had been diagnosed as appendicitis by her medical attendant, who recommended operation. All her life she had been subject to obstinate constipation, frequently requiring enemata. Examination showed her to be a well-developed, well-nourished girl of wholesome colour. The abdomen was of normal appearance, but palpation showed an area of marked tenderness at and a little above McBurney's point, with the right rectus muscle on guard. The temperature was normal, and the pulse-rate 96. There was no nausea or vomiting during the existing attack, though she had sometimes vomited during previous attacks. A provisional diagnosis of appendicitis

was made and the abdomen was opened. There was a very large cæcum distended with semi-solid faeces. Just above the cæcum the ascending colon was narrowed and bound to the right side of the abdomen by a stout, broad pericolic membrane (Jackson's membrane), taking origin from the parietal wall just above the incision. It was evident that this was the cause of the trouble. There was a small peritoneal fold at the ileo-cæcal junction; apparently it was not important. The appendix appeared to be normal. Appendicectomy was done, then the ileo-cæcal band was released, and afterwards the large band incarcerating the ascending colon was dealt with. This left the colon free and unhampered. Next day she was free from pain. For a few months after operation she continued to suffer a good deal from constipation, necessitating enemata at various times. Liquid paraffin relieved the constipation. However, her condition was greatly improved. The pain returned at times, but this, too, was obviously less. The symptoms became less and less, and finally disappeared. She has now for nearly two years been quite well. But another change was even more striking. Although she was physically well developed before operation, her mental development was only that of a child of 12. Further, she had always been subject to attacks of violent and uncontrollable passion, and was most difficult to manage. During the two years that have elapsed since the operation her mental condition has undergone marked improvement. The literature of intestinal bands and kinks is now considerable, but much of it is unconvincing, and Mr. Corlette has remained cautious and somewhat sceptical. He believes that there is something in the indictment against bands and kinks, but that there is a strong tendency to over-estimate their importance. He has loosened a good many bands during abdominal work, but beyond those of definitely inflammatory origin he has not been impressed with their importance as a factor in the production of symptoms. The case now described is an exception. He regards it as an unequivocal demonstration of the trouble produced by a congenital parieto-colic membrane and of the relief following operation.

THE WORK OF PAVLOV.

EARLY in the present year we published a biographical notice of the distinguished Petrograd physiologist Professor Ivan Petrovitch Pavlov, when an erroneous report of his decease reached this country, the confusion being between him and Professor Eugeni Pavlov, a well-known surgeon. Ivan Pavlov's existence among us, and the value of his work, were brought into prominence last week, when his services to physiology formed the subject of a public lecture by Professor W. M. Bayliss at University College, London. In two regions of physiology Pavlov has done pioneer work. His studies of the coördination of the digestive processes are the better known because, though written in Russian, they have been made accessible to French and English readers. Pavlov was not the first to examine the secretions of the alimentary canal by means of artificial fistulæ, but he was the first to make the process a fine art by introducing into the physiological laboratory the precise methods of antiseptic surgery. His institute in Petrograd included a series of rooms in which the experimental animal was first washed and shaved,

next anæsthetised, then submitted to operation, and finally passed on into a series of cubicles forming practically a little hospital. Other institutes, including that at University College, London, have been based on this model. Under these conditions the success of a gastric or intestinal fistula became as certain as that of a simple aseptic operation in man. By means of the gastric fistula Pavlov demonstrated the secretion of gastric juice before food actually reached the animal's mouth, and the absence of such secretion unless the animal regarded his food with relish. Starting from these observations he gradually built up the whole modern teaching of the sequence of the digestive processes. Pavlov's second and equally important work on conditioned reflexes has been less widely recognised, for it is as yet only accessible in original Russian and partly in German translation. He was the first to investigate the functions of the higher centres of the brain by strictly physiological method and to show how extremely modifiable by concurrent circumstances are the reflexes obtained from the higher centres. The building of a new laboratory with thick walls and small windows, in order to shut out disturbing external stimuli, became a necessity for this research. A growing insight into the mechanism of inhibition has been the result of this work, some clue to the essential nature of sleep, and a means of estimating the sensibility of the various sense organs. The lecturer did not suggest it, but it seems likely that Pavlov's work may throw light on the omnipresent factor of inhibition shown by sufferers from shell shock, and that a knowledge of his work on inhibition may prove to be an indispensable preliminary to the proper understanding of the psycho-analytic method. The lecture was attended on behalf of the Russian Ambassador by Baron Heyking, who gracefully acknowledged the growing recognition in this country of the achievements of Russian science. Over and above the originality of his work, amounting to real genius, Pavlov's generosity to his co-workers and pupils has made him the subject of a devoted affection and has formed a link in the chain of the Anglo-Russian scientific entente which is becoming realised.

CASE-TO-CASE INFECTION IN PNEUMONIA.

RECENT authorities agree that while pneumonia is unquestionably a communicable disease, it is not readily transmitted from person to person. Limited epidemics of pneumonia have been described, for the most part before the discovery of the pneumococcus had made the diagnosis a matter of precision. Even in epidemics where this organism has been proved to be the infective agent it must be remembered that the pneumococcus is such a frequent inmate of the fauces and naso-pharynx in health as to make it difficult to prove direct transference from person to person. When in two cases successively occurring in a household the same organism is isolated, the seed may have been lying dormant in each case and some common preparation of the soil have determined the incidence of the disease. The matter is still further complicated by the probability of the existence of healthy "carriers" of this as of the meningococcus. If the pneumococcus were not a single well-defined entity but included differing strains capable of precise identification, transference might more easily be demonstrated. In a brief paper in the June issue of the *Medical Journal of South Africa*, Mr. F. S. Lister contends that this is the case, and he cites, as an instance,

the successive illnesses of a married couple where the husband had acted as nurse to his wife and fell a victim to a precisely similar attack of pneumonia after an interval of 11 days. From the sputum of the second case Mr. Lister isolated, by passage through a mouse, a pneumococcus of a strain "G," which he identified through its agglutination by a stock anti-serum as belonging to a strain occurring but rarely in Europeans in South Africa, and this pneumococcus "G" gave the serological reaction in both the husband's and the wife's case, while no other strain which he tried did so. Recent researches by Dochez, Gillespie, and Avery in America confirm this view of the pneumococcus as a generic rather than a specific organism, and a further application of serological methods of identification may settle the vexed question of the origin of pneumonia epidemics.

ALCOHOL AND THE DEVELOPMENT OF THE FÆTUS.

THE present times have brought about at least one desirable condition of things—the serious problem and the serious man are more likely to receive serious attention than has been the vogue for many years past. More than this, the consideration of the serious problem and the serious man is far less likely to be upset by the pratings of the crank than was the case in times of peace. Into the workings of the legislature and into the workings of the laboratory alike has come a feeling that simple issues must be dealt with upon simple and effective lines, and that the eccentric and the mental gymnast must not be heard too far on questions into the solution of which much common sense and much accumulated human experience enter. For some years past it has been the fashion to pay an undue degree of homage to work which produced results contrary to common sense and accumulated experience. There is no need to single out examples of this type of research, for time and again we have been told that by some method—statistical, bacteriological, or chemical it may be—it had been determined beyond dispute that some custom we all supposed to be healthful was in reality bad, or some habit we all supposed to be noxious in reality did no harm to us nor to our descendants. With the accumulation of very much more of this type of work we might have looked for a day when the visitation of the sins of the fathers upon the children would have been regarded as an archaic formula. Of all questions which touch upon the present and future welfare of mankind, none has been exposed so much to the labours of the eccentric as has that of the influence of parental alcoholism upon the offspring. Common sense prompted the belief that the taking of any toxin into the system of the parent would probably affect the health of the germ cell, and so tend to be a harmful influence upon the well-being of the next generation. Accumulated experience confirmed this belief, and the average man confidently looked to see the children of alcoholic parents suffer in some degree from their parentage. In times of peace, when the breeding of the race up to its maximum of physical and mental effectiveness was not felt to be of the urgent moment that it is to-day, this was a subject in which any startling finding merely made a pleasing mental diversion. To be told that all our ideas upon the subject were wrong was a stimulus to academic argument, and provocative of but little else. But now if common sense and accumulated

experience can be backed by the weight of scientific experiment, and parental alcoholism can be shown to have its harmful effects upon future generations, then academic argument must be laid aside and the facts must plainly be told to a legislature and a people that was never before so well prepared to listen. It is therefore particularly opportune that at this time Dr. J. W. Ballantyne should give a résumé of his life work upon antenatal pathological conditions dependent on parental alcoholism; and should have ready to his hand the experimental results obtained by Stockard and Papanicolaou upon alcoholised guinea-pigs. It becomes abundantly clear that alcoholism in the parent exerts a harmful influence not only upon the individual germ cells (perhaps this is more marked in the male than in the female), but upon the conjoined cells, the embryo, and the foetus; this will be apparent to everyone who has followed Dr. Ballantyne's reasoning in a paper read last week before the Society for the Study of Inebriety. Its conclusion in Dr. Ballantyne's own words runs as follows: "Alcohol is a danger to antenatal health and a menace to antenatal life at every one of the stages of that existence and through each of the progenitors." Cogent teaching such as this must tend to deepen the feeling of individual responsibility. But the hope which the times hold out is now very great; for with the country's need for the fitness of the coming generations it is a wider circle which will pay attention to this thing. Although Dr. Ballantyne observes, "It seems that it is detail which is baffling the strongest of governmental powers even when reinforced by the example and the approbation of monarchs," he must also note that since August, 1914, many salutary ideas have been embraced by this country without the direct intervention of governmental powers. It is in his appeal to "all intending parents" that hope lies, and his moderation of diction makes this hope likely of attainment.

Dr. S. G. Moore (as we have already announced), Dr. Amand Routh, Dr. Comyns Berkeley, and Lady Barrett will introduce the discussion on the Care of Pregnant Women, to be held in the Section of Obstetrics and Gynaecology of the Royal Society of Medicine on Thursday, Nov. 2nd.

THE Conference of Representatives of Local Medical and Panel Committees of the British Medical Association is to begin on Thursday, Oct. 19th, at 10 A.M., in the Connaught Rooms, Great Queen-street, London, W.C., and to continue on the following day if necessary. The Conference is to review the action of the Insurance Acts Committee as a result of the resolutions of the 1915 Conference; to discuss the proposed modifications of the 1917 Agreement; to examine the position of practitioners in connexion with the treatment of venereal diseases; to receive the report of the Insurance Acts Committee of Conference with the Insurance Commission on the present method of remuneration for medical attendance under the Insurance Acts; and to consider the question of collective bargaining by the British Medical Association in regard to agreements between panel practitioners and Insurance Committees. The Local Medical and Panel Committees of each insurance area are asked jointly to send one representative, who need not necessarily be a member of the British Medical Association.

DIPLOMAS IN STATE AND TROPICAL MEDICINE.

It has been usual for us to include in the Students Number of THE LANCET an epitome of the introduction given at various universities and centres of medical education to medical men desiring to obtain diplomas in sanitary science, public health, state medicine, and tropical medicine. During the war some of this work has been suspended, for both teachers and taught being already registered medical men have been required in other spheres. But the public health of the country and of our colonial dependencies must be maintained, for this is one of our greatest guarantees of ultimate success in the struggle of endurance, and the machinery for the special education of public medical servants exists, as appears from what follows, and is ready to resume full activity at the earliest opportunity.

Resolutions, designed with a view of ensuring "the possession of a distinctively high proficiency, scientific and practical, in all the branches of study which concern the public health," have been adopted at various times by the General Medical Council from 1902 to 1911. Certain universities and corporations grant qualifications in Tropical Medicine which have not as yet been made registrable by statute.

University of Oxford.—An examination, conducted partly in writing, partly *visà voce*, and in each subject partly practical, is held in Michaelmas and Easter Terms in the following subjects:—General Hygiene, General Pathology (with special relation to Infectious Diseases), the Laws relating to Public Health, Sanitary Engineering, Vital Statistics. The examination is in two parts, which may be taken together or separately; but Part I. must be passed either before or at the same examination as Part II. The fee for admission to the examination is £5 for each part. Successful candidates are entitled to receive the Diploma in Public Health.

The First Part of the examination will comprise (a) a written paper of three hours in Chemistry and Physics; (b) a three hours' practical and *visà voce* examination in Chemistry and Physics.

The Second Part of the examination will consist of the following parts:—(a) Two written papers, each of three hours, dealing with General Hygiene (including Sanitary Engineering, Vital Statistics, and the Laws relating to Public Health); (b) a practical and *visà voce* examination in General Hygiene; (c) a written paper of three hours in Pathology and Bacteriology; and (d) a three hours' practical and *visà voce* examination in Pathology and Bacteriology.

Candidates in Part I. of the examination will be required to produce a certificate (1) of Laboratory Work in Chemistry as applied to Hygiene.

Candidates in Part II. will produce the following further certificates: (2) of a Practical Knowledge of the Duties, Routine and Special, of Public Health Administration; (3) of having had Practical Instruction in Bacteriology, and the Pathology of the Diseases of Animals transmissible to Man; and (4) of having attended the practice of a Hospital for Infectious Diseases at which opportunities are afforded for the study of the Methods of Administration. The courses of instruction in Chemistry applied to Hygiene and in Pathology and Bacteriology may be taken in the laboratories of any University in the United Kingdom, of any school of the University of London, of the Royal Army Medical College, of University College, Bristol, of any extramural school in Edinburgh, of Anderson's College, Glasgow, The Royal Institute of Public Health, and in any such other laboratory as may, in the case of any particular candidate, be approved of by the Regius Professor of Medicine. In the cases of certificates (2) and (4), the certificates shall be given in such form as shall satisfy the secretary to the Boards of Faculties that the candidate has conformed to the rules of the General Medical Council. The names of candidates must be sent to the Assistant Registrar of the University, Clarendon Building, Oxford, to whom applications for any further information should be addressed.

University of Cambridge.—Two examinations in so much of State Medicine as comprised in the functions of medical officers of health are held during the year. The examination is divided into two parts and demands

proficiency in all the branches of study which bear upon the duties of medical officers of health. The examinations in both parts will be oral and practical, as well as in writing. Candidates may present themselves for either part separately or for both together at their option; but the result of the examination in the case of any candidate will not be published until he has satisfied the examiners in both parts. Marks of distinction will be placed against the names of candidates who have specially distinguished themselves in either (1) general principles of hygiene; (2) bacteriology; (3) chemistry in Part I. of the examination; or (4) the second part of the examination, which has reference to State Medicine and to the applications of Pathology and Sanitary Science. Every candidate will be required to pay a fee of £6 6s. before admission or readmission to *either part* of the examination, but candidates who have presented themselves before the year 1896 will be readmitted to either part on payment of a fee of £5 5s. Candidates must before admission to either part of the examination produce evidence of having satisfied provisions (1), (2), and (3), and before admission to Part II. having satisfied provision (4), above mentioned.

Two Examinations in Tropical Medicine and Hygiene are conducted yearly by the State Medicine Syndicate of the University of Cambridge. The examinations are held in Cambridge early in January and in the middle of August. Each examination will extend over four days.

Any person whose name is on the Medical Register is admissible as a candidate to the examination provided (I.) that a period of not less than 12 months have elapsed between his attainment of a registrable qualification and his admission to the examination; (II.) that he produce evidence, satisfactory to the Syndicate, that he has diligently studied Pathology (including parasitology and bacteriology) in relation to Tropical Diseases, Clinical Medicine, and Surgery at a Hospital for Tropical Diseases, and Hygiene and Methods of Sanitation applicable to Tropical Climates. As evidence of study and attainments a candidate may present to the Syndicate (1) any dissertation, memoir, or other record of work carried out by himself on a subject connected with Tropical Medicine or Hygiene; (2) any Certificate or Diploma in Public Health or Sanitary Science he may have obtained from a recognised Examining Body. Such evidence will be considered by the Syndicate in determining whether he is qualified for admission to the examination and by the examiners in determining whether, if admitted, he shall be included in the list of successful candidates.

The examination will be partly in writing, partly oral, and partly practical and clinical (the clinical part will be conducted at a hospital for tropical diseases, at which cases will be submitted for diagnosis and comment), and will have reference to the nature, incidence, prevention, and treatment of the epidemic and other diseases prevalent in tropical countries. Every candidate who passes the examination to the satisfaction of the examiners will receive from the University a diploma testifying to his knowledge and skill in tropical medicine and hygiene. The fee for the examination is £9 9s., and applications should be addressed to Dr. Graham-Smith, Medical Schools, Cambridge.

All applications for further information respecting these examinations and the courses of study should be addressed to the State Medicine Syndicate, the Chemical Laboratory, Pembroke-street, Cambridge.

University of London.—Candidates for the M.D. degree may offer State Medicine as a subject in which to graduate. Certificates must be produced showing that a course of practical instruction has been attended for the prescribed period, and that the course has included such chemical, microscopical, and meteorological work and exercises as more especially relate to sanitation. The attendance includes six months' practical instruction in a laboratory and six months' instruction in public health administration under the supervision of a medical officer of health, and three months' attendance on the practice of a hospital for infectious diseases. The examination consists of papers in State medicine, including hygiene, school hygiene, and forensic medicine; a paper in medicine; an essay; and a two days' practical examination. Candidates must satisfy the examiners both in the papers and in the practical tests. A *visà voce* examination may be held at the discretion of the examiners. In connexion with this degree the various

metropolitan medical schools hold regular classes under teachers of Public Health and Sanitary Science, such instruction being also used to obtain the various diplomas of other Universities and of those Royal Corporations which grant them.

University of Durham.—Sanitary Science is the special object of the degrees in Hygiene. Candidates for the degree of Bachelor of Hygiene (B.Hy.) must be at least 22 years of age, registered, and a graduate in Medicine of a recognised university. They must spend six months at Newcastle-upon-Tyne studying Comparative Pathology, Practical Bacteriology, Sanitary Chemistry, and Physics, and have to pass an examination in Sanitary Chemistry, Physics, Comparative Pathology, Sanitary Legislation, Vital Statistics, Nosology, Climatology, Meteorology, Distribution of Health and Disease, Sanitary Medicine and Practical Hygiene. The fee for the examination for the degree of B.Hy. is 10 guineas and for the degree £6 6s. Candidates for the degree of Doctor of Hygiene (D.Hy.) must have acquired the degree of Bachelor of Hygiene, must for two years subsequently have been engaged in Public Health administration, or in research work relating to Public Health. The fee for the examination for the degree of D.Hy. is £5 and for the degree £6 6s. The regulations for examination for the Diploma in Public Health (D.P.H.) are the same as those for the degree of Bachelor of Hygiene, except that the candidate is not required to be a graduate in Medicine of a recognised University and the course of study need not be passed at Newcastle-upon-Tyne. The fee for the examination is 10 guineas and for the Diploma £3.

Victoria University of Manchester.—An examination in Public Health is held twice yearly. The examination is in two parts and is written, oral, and practical. Candidates may present themselves for Parts I. and II. separately or at the same time, provided that no candidate be admitted to Part II. unless he has already passed in Part I. No candidate's name will be published until he has satisfied the examiners in both parts of the examination. The fee for each part is £5 5s., and must be paid on or before July 1st in each year. For any subsequent examination in the same part the fee will be £3 3s. Every candidate who has passed both parts of the examination to the satisfaction of the examiners, and who is legally registered, will receive a Diploma in Public Health. The examinations will begin about the end of March and the middle of July in each year. Holders of the Diploma in Public Health are eligible for examination for the Certificates in School Hygiene and Factory Hygiene after attending the prescribed periods of study and hospital practice.

University of Birmingham.—The University grants a degree of B.Sc. in Public Health and also a Diploma in the same subject on the following conditions: Graduates in Medicine of this University may become candidates for the degree of Bachelor of Science in Public Health, by conforming to all the requirements laid down for candidates for the Diploma in Public Health, except that after graduating in Medicine all courses of study must be taken out in the University, and they must, in addition, have attended a three months' course of Geology in the University. The examinations will be held in the months of March and June and will consist of two parts, each part being written, oral, and practical. No candidate will be allowed to pass Part II. until he has passed Part I. Candidates may enter for Parts I. and II. separately or at the same time. The fee for each part of the examination is £5. Medical Officers of the Royal Navy who have attended courses in Hygienic Chemistry, Bacteriology, and Public Health at the Naval Medical School, Greenwich, will be admitted to the examinations for the Diploma in Public Health, whether they have previously been students at the Birmingham School or not; and the same applies to officers of the Royal Army Medical Corps who have studied Chemistry and Bacteriology at the Staff College and pursued the further course of study approved by the General Medical Council.

University of Liverpool.—The University grants a Degree in Hygiene (M.H.) and a Diploma (D.P.H.), and every facility is afforded for training in Sanitary Science and State Medicine. The curriculum for the Degree extends over a period of two years, the first of which is devoted to laboratory instruction and practical classes (including those for the Diploma); the second being devoted to advanced

study and research. The D.P.H. curriculum fees are: Chemistry, £5 5s.; Bacteriology, £5 5s.; Practical Sanitation, £15; Infectious Diseases, £3 3s. The courses may be taken out at any time, and students are allowed to work daily in the laboratories.

The University grants a Diploma in Tropical Medicine. Three courses of instruction are given every year. Two of these last for three full months—the Lent Course from Jan. 6th to April 5th and the Autumn Course from Sept. 15th to Dec. 13th. The Third Course, an Advanced Course, lasts one month, from June 1st to the 30th. At the end of each full course an examination is held by the University for its Diploma of Tropical Medicine (D.T.M.), which is open only to those who have been through the course of instruction of the school. The examination lasts three days and consists (1) of papers on Tropical Medicine, Tropical Pathology, and Tropical Sanitation and Entomology respectively; (2) of a clinical examination; and (3) of an oral examination. The advanced course consists entirely of Practical and Clinical Laboratory Work, given at the laboratory at the University. The fee for the full course of instruction is 13 guineas, with an extra charge of 10s. 6d. for the use of a microscope if required. The fee for the examination is 5 guineas. Applications should be made to the Dean of the Medical Faculty, University of Liverpool. Two University Fellowships of £100 a year each are open to students of the school, amongst others. Accommodation for research work is to be had at the University Laboratory. The Mary Kingsley Medal is awarded by the school for distinguished work in connexion with Tropical Medicine. The new laboratories are completed and ready for occupation on the termination of the war.

University of Leeds.—The University grants a Diploma in Public Health, and every facility is afforded for training in Sanitary Science and State Medicine. The examination, which is held twice in each year—namely, in June and December—is in two parts, and is written, oral, and practical. Candidates, before entering for the first part of the examination, must have held for not less than 12 months a registrable qualification in Medicine, Surgery, and Midwifery, and must present satisfactory certificates of having attended an approved course of instruction in Public Health in the University, or in a college or medical school recognised for this purpose by the University. Candidates before entering the second part of the examination must present certificates of having, after obtaining a registrable qualification, attended during not less than three months the clinical and administrative practice of a hospital for infectious diseases approved by the University. Candidates may present themselves for Parts I. and II. separately or at the same time, provided that no candidate be allowed to pass in Part II. unless he has already passed in Part I. Fees—The fee for each part is £5 5s., and for any subsequent examination in the same part £3 3s.

University of Sheffield.—The examinations for the Diploma in Public Health are open to all registered medical practitioners who have completed approved courses of study. The examination shall be in two parts. The subjects of the examination in Part I. shall be Chemistry and Bacteriology. Candidates may present themselves for examination in the subjects of Part I. either separately or at the same time. The subjects of the examination in Part II. shall be the General Principles of Public Health, with especial reference to Epidemiology, trade diseases, sanitation, inspection of articles of food, the storage and purification of water, and the principles of drainage. Parts I. and II. of the examination may be taken separately or at the same time. Courses of lectures and practical instruction in the subjects of the examination are given at the University. These courses may be attended by students intending to become candidates for the Diploma in Public Health of other Universities.

University of Bristol.—Diploma in Public Health. Candidates must be at least 23 years of age, shall be fully registered medical practitioners of not less than 12 months' standing as such, and shall have passed the examination prescribed by regulation. The examination is divided into two parts. The subjects of the First Part are Chemistry as applied to Public Health and Pathology and Bacteriology. Candidates for the First Part shall, during six months after having obtained a registrable qualification, have received practical laboratory instruction in Hygienic Chemistry, in

Bacteriology, and in the Pathology of the Diseases of Animals Transmissible to Man. The subjects of the Second Part are: Public Health and Epidemiology, Sanitary Law, Vital Statistics, and Sanitary Reporting. Candidates for the Second Part shall, during six months after having obtained a registrable qualification, have been diligently engaged in acquiring a practical knowledge of the duties, both routine and special, of public health administration under the supervision of certain persons specified by the General Medical Council, a list of which can be obtained from the prospectus.

University of Edinburgh.—Two degrees in Science in the Department of Public Health are conferred by the University of Edinburgh—viz., Bachelor of Science in Public Health and Doctor of Science in Public Health. A Diploma in Tropical Medicine and Hygiene is also granted. Candidates for the degree of B.Sc. in Public Health must be graduates in Medicine of a recognised University, and must pass two examinations, for the first of which they must, after graduation in Medicine, have worked for at least 20 hours per week during a period of not less than eight months, of which at least five consecutive months must be in the Public Health Laboratory of the University of Edinburgh and the remainder either there or in a laboratory recognised by that University; they must also have attended courses of instruction in Physics and Geology in some Scottish University. Candidates are admitted to the Second Examination six months after having passed the First Examination, and must have attended two courses in Public Health approved for the purpose by Edinburgh University, each course consisting of 40 lectures at least; one of which courses shall deal with medicine and the other with engineering, each in its relation to public health. Graduates who have held the degree of B.Sc. in Public Health from the University of Edinburgh for a term of five years may offer themselves for the degree of D.Sc. in Public Health in that University. The fees are £3 3s. for the First and £3 3s. for the Second B.Sc. Examinations, and £10 10s. for the degree of D.Sc.

University of Aberdeen.—The Diploma in Public Health (D.P.H.) is conferred only on graduates in Medicine of a University in the United Kingdom not less than 12 months after medical graduation. Every candidate must produce evidence of having attended, after graduation in Medicine, during a period of six months, practical instruction in Hygiene and Bacteriology in laboratories approved of by the University, together with having during six months (whereof three months must be distinct from the period of laboratory instruction) been diligently engaged in acquiring a practical knowledge of the duties, routine and special, of Public Health administration under the medical officer of health of a county or large urban district. He must have regularly attended for three months the practice of a hospital for infectious diseases at which opportunities are afforded for the study of methods of administration. He must also have obtained practical instruction in the drawing and interpretation of plans. The diploma is conferred after an examination in Public Health held in March and July of each year. The fee is £5 5s.

University of Dublin (Trinity College).—The Diploma in Public Health is conferred, after examination, on the following conditions. The candidate must be a registered medical practitioner and have obtained a registrable qualification at least nine months before the examination. The candidate must have completed, subsequently to obtaining a registrable qualification, four months' practical instruction in a chemical and bacteriological laboratory or laboratories approved by the University, must have studied practically outdoor sanitary work for six months under an approved officer of health, and must have spent three months in a fever hospital where opportunities are afforded for the study of methods of administration. A special prospectus and a list of recognised laboratories may be obtained by application to the Registrar of the School of Physic, Trinity College, Dublin.

National University of Ireland.—At this University there is a Diploma in Public Health and a B.Sc. in Public Health. The Diploma may be granted to matriculated or non-matriculated students of the University who shall have completed approved courses of study and shall have passed the prescribed examinations, provided that it shall not be granted except to a registered medical practitioner. Candidates may present themselves for the examination after

an interval of not less than 12 months from the time of obtaining a registrable qualification. The curriculum extends over a period of not less than nine calendar months. Every candidate must produce a certificate that he has attended practical instruction in a laboratory, approved by the University, in Chemistry, Bacteriology, and the Pathology of the diseases of animals transmissible to man. The examination consists of two parts, which may be passed separately or together. Part I. comprises the following subjects: Chemistry, Meteorology and Climatology, and Sanitary Engineering and Architecture. Part II. comprises the following subjects: Bacteriology, Hygiene, Sanitary Law, and Vital Statistics. The examination in each part will be oral and practical as well as written.

For the B.Sc. in Public Health a candidate shall not be admitted unless he (a) shall have received the degrees of M.B., B.Ch., and B.A.O. at least one year previously; (b) shall have pursued an approved course of study in the Faculty of Medicine; and (c) shall have passed the prescribed examination. In addition to D.P.H. course the candidate will be required to take up (1) a Special Course of Pathology; (2) Bacteriology; and (3) Advanced Course in Hygiene. Each of these courses lasts three months.

University of Belfast.—A Diploma in Public Health is given by examination. Every candidate must produce evidence that, after obtaining a registrable qualification, he has during six months received practical instruction in an approved laboratory in which Chemistry, Bacteriology, and the Pathology of the diseases of animals transmissible to man are taught. After obtaining a registrable qualification every candidate must produce evidence that he has attended during three months the practice of a hospital for infectious diseases at which opportunities are afforded for the study of methods of administration. The examination must have extended over not less than four days, one of which shall have been devoted to practical work in a laboratory, and one to practical examination in, and reporting on, subjects which fall within the special outdoor duties of a medical officer of health. The examination will be held once yearly, Part I. in March, and Part II. in June. The first part of the examination will have reference to the general principles of sanitary science, and the second part to State Medicine and to the applications of Pathology and Sanitary Science. The fee for each part is 1 guinea.

Royal College of Physicians of London and the Royal College of Surgeons of England.—The following are the regulations for obtaining the Diploma in Public Health: The examination consists of two parts. The first part of the examination takes place in January, April, and July, and the second part in January and July. The fee for each part is £10 10s., except for those who are diplomates of the Royal Colleges, who pay £6 6s. for each part. A candidate intending to present himself must give 14 days' written notice to the Secretary, at the Examination Hall, Queen's-square, Bloomsbury, W.C. He will be admissible to examination in Part I. on producing evidence (1) of having been in possession of a registrable qualification for at least 12 months; (2) of having attended thereafter practical instruction in a laboratory recognised by the Examining Board in England for at least 240 hours during a period of six months; and (3) of being at least 23 years of age. A candidate will be admitted to Part II. of the examination on producing evidence (1) of having been diligently engaged in acquiring a practical knowledge of Public Health administration during six months under certain specified conditions; (2) of having attended during three months the clinical practice of a hospital for infectious diseases; and (3) of being at least 24 years of age.

The Examination for the Diploma in the Diseases and Hygiene of the Tropics has been discontinued during the war.

The Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, the Royal Faculty of Physicians and Surgeons of Glasgow.—All candidates for the Diploma in Public Health must have a qualification which has been registered under the Medical Acts. Candidates must have attended not less than four calendar months' practical instruction in Chemistry and Bacteriology in a recognised laboratory or laboratories, must have studied outdoor sanitary work for six months under a medical officer of health or other sanitary officer; and must give evidence of attendance for three months at the practice of a Hospital for Infectious Diseases, at which he has

received instruction in the methods of administration. The examination consists of two parts, and candidates may enter for both at one period or for either separately. The First Part includes (a) Laboratory Work (Chemistry and Bacteriology), (b) Physics and Meteorology; and the Second Examination embraces (a) Report on Premises visited, (b) Examination at Fever Hospital, (c) Examination at Public Abattoir, (d) Written and Oral Examinations on Epidemiology and Endemiology, (e) Vital Statistics and Sanitary Law, and (f) Practical Sanitation. The fee is 12 guineas for both examinations, or 6 guineas for either of them. A fee of 3 guineas is payable by rejected candidates for either examination. The examination is held twice yearly, in May and October. The published regulations provide detailed synopses of the subjects of examination. The Registrar for Edinburgh is Mr. D. L. Eadie, 50, George-square, and for Glasgow Mr. Walter Hurst, 242, St. Vincent-street.

Royal College of Physicians of Ireland and Royal College of Surgeons in Ireland.—Every candidate for the Diploma in Public Health must be a registered medical practitioner. He must subsequently to qualification (1) receive six months' laboratory instruction in Chemistry, Bacteriology, and the Diseases of Animals transmissible to man; and (2) during six months practically study outdoor sanitary work under a medical officer of health, and shall as an additional requirement attend a hospital for infectious diseases. Candidates are examined on four days, commencing on the first Monday of February, May, and November. The examination comprises the following subjects:—Hygiene, Chemistry, Meteorology and Climatology, Engineering, Vital Statistics, Sanitary Law, and Bacteriology. The fee for the examination is £10 10s. For further particulars apply to Alfred Miller, Secretary, Committee of Management; Office, Royal College of Surgeons, Dublin.

THE SERVICES.

ROYAL NAVAL MEDICAL SERVICE.

Temporary Surgeons: H. E. Scowcroft to *Victory*, for R.N. Barracks; and G. Lillico to *Vernon*.

ROYAL NAVAL VOLUNTEER RESERVE.

Surgeon: W. H. Bleden to *Blake*.

ARMY MEDICAL SERVICE.

Temporary Colonel V. W. Low, C.B. (Captain, R.A.M.C., T.F.), relinquishes his temporary commission.

ROYAL ARMY MEDICAL CORPS.

Captain Frank A. Hepworth, R.A.M.C., T.F., to be temporary Major whilst employed at the Wharnclyffe War Hospital.

To be temporary Captains whilst employed at the Keighley War Hospital:—J. N. Dobie and J. M. Crocker.

Robert Spence Barnard (Fleet Surgeon, R.N., retired) to be temporary Honorary Captain.

Temporary Lieutenant H. E. Newman relinquishes his commission on account of ill-health.

Temporary Honorary Lieutenant F. W. Goyder to be temporary Honorary Captain whilst employed at the St. John Ambulance Brigade Hospital.

A. T. Paterson to be temporary Honorary Lieutenant whilst employed with the St. John Ambulance Brigade Hospital.

ROYAL ARMY MEDICAL CORPS: SPECIAL RESERVE OF OFFICERS.

Lieutenant J. M. Watt to be Captain.

Temporary Lieutenant G. H. Barry, from Lancashire Fusiliers, to be Lieutenant.

ROYAL ARMY MEDICAL CORPS: TERRITORIAL FORCE.

West Lancashire Field Ambulance: Major R. Coffey to be temporary Lieutenant-Colonel whilst commanding a Field Ambulance.

East Anglian Field Ambulance: Lieutenant E. N. Hoffmeister to be Captain.

Wessex Field Ambulance: Major T. P. Puddicombe to be temporary Lieutenant-Colonel whilst commanding a Field Ambulance. Captain (temporary Major) H. N. Collier relinquishes his temporary rank on ceasing to command a Stationary Hospital.

Home Counties Field Ambulance: Captain J. R. Chalmers, from T. F. Reserve, to be Captain.

Wessex Casualty Clearing Station: Lieutenant Cyril A. Raison to be Captain.

Attached to Units other than Medical Units.—Major T. Kay to be temporary Lieutenant-Colonel whilst commanding a Field Ambulance. Lieutenant J. E. S. Wilson to be Captain.

"Audi alteram partem."

MEDICAL CERTIFICATES AND FITNESS FOR MILITARY SERVICE.

To the Editor of THE LANCET.

SIR,—I cannot agree with Surgeon-Captain G. Sherman Bigg, whose letter on this subject appeared in your issue of Oct. 7th, that "the civilian practitioner practically is bound to give to a patient a certificate, but he words it in such a way that an intelligent military medical officer should be able to read between the lines," although no doubt this practice has prevailed to some extent, and much of "the differences of opinion" between military and civilian medical men may so be accounted for.

One is well aware of the pressure that is brought to bear upon the family doctor by anxious parents, interested business connexions, or the applicant himself, who is very apt to confuse his business interests with his health condition; but it is the duty of the civilian practitioner to advise his patient frankly whether there is or is not any physical or mental condition rendering him wholly or partially unfit for military service, and it seems to me that any certificate given for the consideration of the medical officer of the recruiting centre should plainly put the grounds upon which the medical opinion is based. The military medical officer cannot be expected to have time or inclination to "read between the lines."

Of course, the last word must be with the responsible military medical officer, but in my experience he, as a rule, gladly avails himself of any information given by private medical practitioners, when clearly expressed.

I am, Sir, yours faithfully,

Oct. 9th, 1916.

R. DOUGLAS POWELL.

THE PREVALENCE OF VENEREAL DISEASES IN THE TROPICS.

To the Editor of THE LANCET.

SIR,—In reading the report of the recent Royal Commission on Venereal Diseases one is struck, as a practitioner in the tropics, at the lack of reference to the tropical colonies as a source of infected individuals. In Appendix 7 mention is made in the case of Liverpool that the worst cases are those infected abroad. No mention is made of the relative numbers. The case-books of the syphilologists in London would, I think, show a very large proportion of cases from the various tropical colonies.

The Colonial Medical Service has to some extent followed the Army and Navy in providing facilities for special work, but not, as far as I am aware, in venereal diseases. There are probably no statistics on the matter apart from hospital records, but most medical men in the tropics would, I think, endorse the view that there is much invaliding and loss of efficient work both among the official and unofficial members of the European community. My reason for writing this letter is that I deem the present time an opportune one to draw attention to the subject in countries where such diseases are not only very common but, owing to the climate and the presence of tropical disease, difficult to cure.

I am, Sir, yours faithfully,

RICHARD ROPER.

Ipoh, Federated Malay States, Sept. 9th, 1916.

THE NURSING PROFESSION IN INDIA.

To the Editor of THE LANCET.

SIR,—In a note under the above heading in THE LANCET of August 5th you say that the result of Dr. Masina's experiment to attempt to induce educated ladies of the Parsi community to train as sick nurses will be watched with interest, not only by the Parsi community but by the Indian community at large. It is not out of place in this connexion to draw your attention to the fact that in Bengal the Lady Carmichael Nursing Association is training nurses at the Sambunath Pundit Hospital in Calcutta, at the Scotch

Mission Hospital at Kalimpong, and at the Victoria Hospital in Darjeeling. The material is excellent, and the progress achieved in training is remarkable, reaching a standard far beyond that for which it seemed justifiable to hope a year ago. The result of this experiment in Bengal merits at least as close an interest on the part of the Indian community at large as does the training of Indian nurses in the Western Presidency to which you refer.

I am, Sir, yours faithfully,

Darjeeling, Sept. 15th, 1916.

CLAYTON LANE.

ALCOHOL IN THE TROPICS.

To the Editor of THE LANCET.

SIR,—How Dr. Lucas Benham could write about alcohol as he does in your issue of Sept. 23rd passes my comprehension. I am not a bigot. I use alcohol when indicated. Often I administer brandy to patients recovering from cholera, &c., but the man in the East who commences to drink whisky, &c., is playing with fire; he may not get burnt, but he generally does. I have been working in a Chinese port, and my experience all goes to prove that club life, lonely stations, human frailty—all tend to make easy the descent to a drunkard's grave.

If Dr. Benham does not know this he has either gone through life with his eyes shut, or else has never lived in the tropics.—I am, Sir, yours faithfully,

C. G. S. BARONSFEATHER, M.D. Dub.

Kingstown, co. Dublin, Oct. 4th, 1916.

MEDICAL WOMEN AND EQUALITY OF PAY.

To the Editor of THE LANCET.

SIR,—I write to draw attention to the worse terms offered to medical women as compared with men by both the Ministry of Munitions and the War Office. The former is trying to obtain women doctors for munition works at £400 a year, while men receive £500. The War Office does not pay the £30 for outfit nor give rank. We women doctors have stood out so hard for equal pay for equal work that it is to be hoped these differences will be rectified.

I am, Sir, yours faithfully,

Colwall, Malvern, Oct. 3rd, 1916.

MARY H. WILLIAMS.

THE EFFECT OF FRESH HUMAN BLOOD SERUM ON ARTIFICIAL MEDIA.

To the Editor of THE LANCET.

SIR,—With reference to the articles on this subject in your issues of August 19th and Sept. 2nd, we have recently had occasion to examine several specimens of serum ultra-microscopically. When freshly drawn the insoluble colloidal protein contained therein displays far greater Brownian movement than if the serum has been standing some time. The ultra-microscopic appearance of serum is very similar to that of collosol iodine. The combination of amino-acids, which is the protective of the colloidal protein in serum (the latter, of course, containing the electrolyte sodium chloride, which would naturally destroy the colloidal condition but for the presence of protective) is more perfect than we have hitherto been able to manufacture, although we approximate very closely thereto. In our experience the germicidal value of a colloidal solution to some extent depends upon the amount of Brownian movement displayed by the individual particles. If this is so in the case of serum the reason why fresh serum should not be employed as a medium is evident; indeed, it is probable that absolutely fresh serum would exhibit mild germicidal properties. On the other hand, if fresh serum were subjected to ultra filtration in order to remove the colloidal protein it is probable that a perfect growing medium would be obtained. As a matter which might perhaps open a field for investigation, in the few cases which we have been able to investigate, the individual particles in protozoal serum appear larger than those in normal serum.

I am, Sir, yours faithfully,

JOHN WARD,

Elgin-crescent, W., Oct. 4th, 1916. Manager, Crookes' Colloids, Ltd.

MISS EDITH CAVELL AND HOMES OF REST FOR NURSES.

To the Editor of THE LANCET.

SIR,—Will you kindly allow me to take advantage of the fact that Oct. 12th is the first anniversary of the death of my sister, Edith Cavell, to say that she had long cherished the idea of establishing homes of rest for nurses. She had hoped to devote the latter years of her life, when her work in Brussels had finished, to providing places where nurses in need of temporary mental and physical rest from their work could receive the benefit of a real home, and so become again able to take up the burden of life with some chance of success.

After serious thought I decided to try to put my sister's project into practical shape, and I am glad to say that I have met with strong and wide support. An influential council has already been formed, and its members have satisfied themselves that there is a definite need for such homes in the nursing world. It is certain that this need will become increasingly acute as the war continues, and that when the war is over it will remain acute for a considerable period thereafter. This consideration alone should find an echo in the hearts of all desirous of helping those who have devotedly laboured in a time of national stress, who are interested in the welfare of working women, and who love and respect the memory of Edith Cavell, who gave her life to the profession of nursing.

May I add that a freehold house standing in about 3½ acres of ground in a most suitable locality, which will deal with the needs of about 100 nurses yearly, has been offered to me as a gift, provided that a fund sufficient for its permanent endowment as a home can be raised. And, lastly, may I hope that when the council puts forth its appeal it may find a response in all parts of the British Empire.

I am, Sir, yours faithfully,

F. M. SCOTT CAVELL.

The Hull and East Riding Convalescent Home, Withernsea, E. Yorks.
Oct. 10th, 1916.

* * We have received a list, as yet a private one, of those who have already consented to join the council. They form an influential group of men and women, representative in every respect. We recommend the movement cordially to our readers as one for which they should obtain support from their patients. Donations may be sent to either Major W. McAdam Eccles, 124, Harley-street, W., or Mr. R. Martin-Holland, Martin's Bank, 68, Lombard-street, E.C., the treasurers of the fund.—ED. L.

By a misreading of the manuscript, the affix "Mrs." was added to Mr. E. W. Hutton's signature in the letter which appeared from him last week pleading for routine radioscapy in military hospitals. Mr. E. W. Hutton is the chief radiologist at the Hôpital Notre Dame des Grèves, St. Malo.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.—The first selection of President of the Royal College of Physicians under the new scheme took place last week, and has resulted in the nomination of Dr. Joseph F. O'Carroll, professor of medicine in University College, Dublin. On the last Friday in September the Fellows selected by ballot three candidates for the Presidency, of whom Dr. O'Carroll was one. The other two having signified their unwillingness to accept the office, Dr. O'Carroll's name will be submitted formally for election on St. Luke's Day.

THE LATE DR. ST. CLAIR B. SHADWELL.—Dr. St. Clair Shadwell, a well-known practitioner in the North-East of London, died at his residence at Walthamstow on Sept. 23rd, at the age of 64. He received his medical education at Guy's Hospital, obtaining the Membership of the Royal College of Surgeons of England in 1875. Subsequently, in 1891, he took the D.P.H. of the English Conjoint Board, and graduated M.D. of St. Andrews University four years later. After holding appointments at Guy's Hospital and the Great Ormond-street Hospital, he entered upon medical practice at Walthamstow, where he was consulting medical officer to the Dispensary, and for 13 years medical officer of health. He also had held the posts of certifying factory surgeon, medical examiner to the Board of Education and medical officer to the Post Office. An ardent Volunteer, he joined the movement quite early in his career, and received the V.D., retiring with the rank of Surgeon-Lieutenant Colonel of the 1st Volunteer Brigade Essex Regiment.

The War.

THE CASUALTY LIST.

THE following names of medical officers appear among the casualties announced since our last issue:—

Killed.

Capt. S. Clark, R.A.M.C., was a student at King's College Hospital, London, and qualified in 1896. He had held appointments at King's College Hospital and at Leeds General Infirmary, and was in practice at Fulham-road, London, prior to joining the R.A.M.C.

Capt. T. L. Ingram, D.S.O., M.C., R.A.M.C., attached King's Shropshire Light Infantry, was educated at Cambridge University and at the London Hospital, and qualified in 1903. He was at one time house surgeon at the Westminster Hospital and also at the Poplar Hospital, and when he joined the R.A.M.C. he was a medical officer of the Lutterworth Union and of the Market Harborough Union.

Capt. W. F. MacAlevey, R.A.M.C., was a student at St. Mary's Hospital, London, and qualified in 1915. He thereupon joined the R.A.M.C., and obtained his captaincy in February last.

Capt. F. S. Walcott, R.A.M.C., attached Northumberland Fusiliers.

Capt. E. R. Welch, R.A.M.C., attached Durham Light Infantry.

Died.

Surgeon W. H. Edmunds, R.N., qualified L.M.S.S.A. Lond. in 1913.

Wounded.

Capt. L. Adamson, R.A.M.C.

Capt. G. D'R. Carr, R.A.M.C., attached Sherwood Foresters.

Capt. H. Mathews, R.A.M.C., attached Northampton Regiment.

Capt. N. J. Barton, Canadian Army Medical Corps.

Capt. H. W. Baily, R.A.M.C.

Lieut. W. A. Cochrane, R.A.M.C., attached Leicestershire Regiment.

Lieut. J. N. Cruikshank, R.A.M.C., attached Liverpool Regiment.

Lieut. T. M. Crawford, R.A.M.C.

Capt. W. C. Stewart, R.A.M.C.

Capt. B. N. Murphy, R.A.M.C., attached Coldstream Guards.

Lieut. J. Oag, R.A.M.C., attached Manchester Regiment.

Capt. O. A. Elliott, Canadian Army Medical Corps.

Capt. W. R. Pagen, R.A.M.C., attached East Kent Regiment.

Capt. E. R. Selby, Canadian Army Medical Corps, attached Canadian Infantry.

Previously reported presumed Prisoner at Kut-el-Amara, now reported Prisoner in Turkish Hands.

Capt. L. Murphy, R.A.M.C.

DEATHS AMONG THE SONS OF MEDICAL MEN.

The following sons of medical men must be added to our lists of those who have fallen during the war:—

Second Lieut. C. T. Rennie, Leicestershire Regiment, son of Dr. G. E. Rennie, J.P., of Sydney, New South Wales.

Lieut. G. J. R. Saunders, South Lancashire Regiment, attached Leicestershire Regiment, youngest son of Dr. E. A. Saunders, J.P., of Pembroke Dock, South Wales.

Second Lieut. S. M. Scott, Coldstream Guards, younger and only surviving son of the late Mr. J. H. Scott, F.R.C.S.I., of Dublin.

Capt. W. F. MacAlevey, R.A.M.C., son of Dr. W. C. MacAlevey, of Leicester.

Lieut. M. Wheeler-O'Bryen, Royal Warwickshire Regiment, elder son of Dr. J. Wheeler-O'Bryen, of Sydenham, London, S.E.

G. Addison, Canadian Expeditionary Force, eldest son of Dr. W. B. Addison, of the Scilly Isles.

HOSPITALS FOR WOUNDED OFFICERS.—A temporary hospital for officers, which after the war will be transferred to permanent quarters as a Russian Hospital in London, is to be opened in a house in South Audley-street, lent for the purpose by Sir Berkeley and Lady Sheffield. M. Mouravieff-Apostol and his wife are the donors of the new institution.—The Government has taken over possession of the Great Central Hotel, Marylebone, as a convalescent home for wounded officers. The building contains some 500 rooms.

OBITUARY OF THE WAR.

MORTON PETO, M.B., CH.B. LEEDS,
CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain M. Peto, who died of wounds on Sept. 22nd at the age of 26 years, was the fourth son of the late Rev. A. H. Peto, of Leeds. Educated at Leeds Grammar School, he went on to the University and Medical School in Leeds. After

graduating M.B., Ch.B. in 1912, he held resident posts at the Women and Children's Hospital, and at the outbreak of war he resigned the appointment of ophthalmic house surgeon at the General Infirmary to take a commission in the R.A.M.C. At first in charge of a field ambulance, he was later attached to the Cameron Highlanders and the Royal Berks Regiment. He was mentioned in Lord French's last despatch and was awarded the Military Cross for gallant conduct in June, 1916. The night

before he met his death he had undertaken some dangerous work for the rescue of wounded men. This was successfully accomplished, but on returning from the first lines the following morning he was wounded by a shell and died the same day.

A colleague on the Headquarters Staff writes of Captain Peto: "He and I worked shoulder to shoulder in some very heavy fighting, and he helped me by his dauntless bravery and coolness under fire to do what I could to follow his example. His first thought was always for the wounded, and he faced any risk to succour them. His example will always remain to me a shining one, though his cheery presence and charming personality are no longer with us."

ARTHUR JOHN WAUGH, B.A. CANTAB., M.R.C.S.,
L.R.C.P. LOND.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain A. J. Waugh, who was killed in action in France about August 18th at the age of 28, was the third son of Mr. and Mrs. Walter Waugh, Chigwell Hall, Essex. He was educated at Forest School, and proceeded to Pembroke College, Cambridge, and afterwards to St. Bartholomew's

Hospital, where he later filled the post of house physician. Subsequently he was appointed resident medical officer at the East London Hospital for Children. He resigned this appointment at the outbreak of war to take a commission in the Royal Army Medical Corps, and was promoted to captain about the middle of 1915. He had been attached to the North Staffordshire Regiment since 1914. He was instantly killed by a 4.2 shell which fell almost at his feet

whilst he was waiting for the relief force. Captain Waugh was buried at Carnoy, and the cross on his grave has been inscribed "Pectore Robur," the Forest School song. The colonel and adjutant of the regiment have written very kind sympathetic letters, and speak most highly of his work, regretting the loss they and the regiment have sustained by the death of their good friend and companion. Captain Waugh was well known in amateur cricketing and football circles.

REGINALD JOSEPH WOOSTER, M.R.C.S. ENG.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain R. J. Wooster, who was killed on active service on Sept. 15th, at the age of 29 years, was fifth son of J. Ratliff Wooster, of Ealing. He was educated at St. Paul's School and St. Mary's Hospital Medical School, qualifying in 1911, and then holding in succession three house appointments. He obtained

a commission in the R.A.M.C. after he had entered for the F.R.C.S. examination, and was attached to the Rifle Brigade. After working for some time as a garrison medical officer in France he rejoined a field ambulance. One of his chiefs writes of Captain Wooster that he was an energetic man who knew his work well and who proved a very capable resident medical officer. The facts that he was popular with his colleagues, both in civil and military life, and

that he left behind him a record of ability and industry are noted by more than one correspondent.

J. LISTER GODDARD,

LIEUTENANT, NORFOLK REGIMENT.

Lieutenant J. L. Goddard, who was reported on Sept. 22nd last as wounded and missing and, a little later, as killed, was the third son of Major C. E. Goddard, of Wembley, President of the Recruiting Medical Board for Chelsea, and was himself destined to be a medical man. Educated at St. George's School, Harpenden, he entered University College as a medical student in 1912, and at the outbreak of war, having just completed his second year of study, he obtained a commission in the Norfolk Regiment, with which he saw service in the trenches for more than a year.

CHARLES EDGAR HOLTON SMITH, L.R.C.P. EDIN.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain C. E. H. Smith, who was killed in action in France on Sept. 16th, at the age of 32, was the eldest son of the late Charles Smith, of Milligan Hall, Taunton. He was educated at College Gaillard, Lausanne, the Moravian School at Neuwied-on-Rhine, and at Aberdeen and Edinburgh Universities, and qualified in 1911. At Aberdeen he belonged to a battalion of the Scottish Horse under Lord Tullibardine. After filling resident posts at the East Suffolk Hospital, Ipswich, and acting as second surgeon to the British Red Crescent Hospital in Tripoli during the Italo-Turkish

War, he went into practice in 1912 at High Green, Cannock, Staffs. He joined the R.A.M.C. as a Temporary Lieutenant on Nov. 1st, 1914, and was promoted to Captain a year later.

Captain Smith, as many letters from brother officers testify, was a fearless officer who gave his time and finally his life ungrudgingly for the safety and well-being of the men under his charge. Captain Smith leaves a widow with two small children.

MIDDLESEX HOSPITAL AND THE ARMY MEDICAL SERVICE.—Surgeon-General M. W. Russell, Deputy Director-General of the Army Medical Service, delivered the introductory address at the Medical School of the Middlesex Hospital this year, and took for his subject the historical connexion between the hospital and the Service. This connexion, he pointed out, began well over 100 years ago, when, during the Revolutionary wars in France, from 1789 on, Frenchmen under the displeasure of the governing powers fled for refuge to England. The Middlesex Hospital then, placed at the disposal of some 30 or 40 of these refugees, destitute and broken in health, wards in which they were housed and nurtured. The first great figure in surgery who worked in the Middlesex Hospital and also with the British Army was Sir Charles Bell. Bell, who came to London in 1804, was, we learn from Surgeon-General Russell, working at the Haslar Hospital in 1809 among the sick and wounded of Sir John Moore's army. In 1815 he went to Brussels to tend the wounded of Waterloo, and of his work at that time the museum of the Royal Army Medical College possesses a wonderful memento in the shape of the water-colour sketches of the wounded whom he attended, Bell being, as is well known, a skilled artist. Two other Middlesex surgeons were mentioned especially by Surgeon-General Russell, John W. Hulke and George Lawson. Both had experience of military surgery in the Crimea, Hulke having worked in the hospitals of Smyrna and before Sebastopol, while Lawson shared in the glories of Alma, Inkerman, and Balacava. The Crimea suggests inevitably the name of Florence Nightingale, and it is interesting to note that she had a characteristic association with "the Middlesex," for in May, 1854, she volunteered to give help to cholera patients who were then being admitted to the wards. They were mostly poor foreigners, the victims of a sharp epidemic in Soho. Surgeon-General Russell concluded an address which, though domestic in theme, was of wide interest in treatment, by alluding to the work done at the Middlesex Hospital and all the other large hospitals during the present war, and at the close of the address the dean of the hospital, Dr. H. Campbell Thomson, stated that 340 past and present students of the hospital had gone on active service, of whom 16 had been killed.

INSPECTION OF MOTOR AMBULANCES BY THE KING.—On Oct. 6th the King inspected at Buckingham Palace a convoy of 25 motor ambulances which the Yorkshire miners have presented to the British Red Cross Society and the Order of St. John. This convoy, which has been sent to France, cost about £15,000.

SCOTTISH WOMEN'S HOSPITALS.—News has been received from beyond Odessa of the hospital units sent out to work for the Serbian division of the Russian Army. The journey was uneventful and the reception of the units cordial. Three sections have been arranged—Hospital A, under Dr. Elsie Inglis; Hospital B, under Dr. Lillian Chesney; and a Transport Section.

MEDICAL SERVICE OF THE ROYAL NAVY.—In Part 3, Vol. IX. of the "Times History and Encyclopædia of the War," just issued, price 8d., there is an appreciative sketch of the part which medical science plays in maintaining the health of the navy and, as a consequence, in the successful prosecution of the war. As the writer points out, the tradition of the navy is to keep silence—"Little was heard by the world of the great work which these sea doctors accomplished, of the heroism revealed by them, of the sacrifices which they offered." This work is now made clear, for the problems which beset the Naval Medical Service in the care of the sailor both before and during an action are explained in a way to bring home to everyone the splendid organisation and traditions of service which belong to the medical as to all branches of the Royal Navy. There is included an inspiring account of medical work during the minor actions in the North Sea and in the great encounter of Jutland Bank, and the psychology of the seaman under the strain to which his nerves are subjected by constant watching and the need for preparedness is discussed in a vivid manner. Among the many illustrations are reproductions of portraits of Sir Arthur May, Director-General of the Naval Medical Service in the War, and of Sir James Porter, the late Director-General.

NEW WELSH HOSPITAL FOR WAR CRIPPLES.—The old Cardiff Mansion House has been purchased with the object of establishing an orthopaedic hospital at Cardiff, similar to that which is already doing good work at Rotherhampton. The accommodation has been increased by the gift of two adjoining houses by the James Howell family. An appeal for funds has resulted in a sum of £20,000, Mr. J. P. Cadogan and Mr. W. Percy Miles giving £5000 each, an anonymous donor £7500, and Messrs. Morgan and Co. £2500.

A NEW ARMY DENTAL CAR.—On Oct. 9th the King and Queen inspected at Buckingham Palace a dental surgery car, the first of its kind to be used by the British Army. It contains two operation chairs, a bench and lathe for repair work, water-supply, gas cylinders for operations, and a sterilising plant. It is, in fact, a completely equipped miniature dental hospital on wheels. The car, which has been designed and built by the engineers of the Royal Automobile Club, whose services have been lent to the Red Cross Society, cost approximately £950, the funds having been supplied by the Civil Service Federation.

Mrs. E. M. N. Green, M.B., B.S., was the recipient last Saturday at Buckingham Palace of the V.C. awarded to her late husband, Captain J. Leslie Green.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At the First Professional Examination of the Conjoint Board held on Sept. 26th, 27th, 28th, and 29th the following candidates were approved in the undermentioned subjects:—

Chemistry and Physics.—Hawa Khairul-Nissa Attaoullah, London School of Medicine for Women; Gerald Cecil Wootton Curson, Guy's Hospital; William Dabbs, special study; Beatrix Helen Fairbanks, Birmingham University; Ralph Wilfrid Fairfax, King's College; Janet Hughes, South-Western Polytechnic; Aziz Yousif Ibrahim, Beirut and King's College; Violet Ruth Jeffery and Horace Abe Nathan, Birkbeck College; Isaac Resnikoff, King's College; Jacob Seelenfreund, London Hospital; and Mary Agnes Elizabeth Somers, Bristol University.

Chemistry.—All Khan Muzaffar Agha, King's College; Charles Spencer Anderson, St. Mary's Hospital; George Frederick Baxter, King's College; Dudley Hugh Cockell, St. Bartholomew's Hospital; Richard Owen Jones, Liverpool University; Tadmor Ibrahim Makar, Assiut and King's College; and Thomas Ben Thomas, St. Bartholomew's Hospital.

Physics.—Mark Louis Barst and Solomon Blackman, London Hospital; Leslie Charles Frederick Chevens, St. Thomas's Hospital; David Hoole, Manchester University; Gerald Israelstam, London Hospital; Colin Campbell Mackinnon, Middlesex Hospital; Mary Colegrave Pridaux, London School of Medicine for Women; Robert Reisser, University College; Gerald Richmond Anderson de Montjole Rudolf, King's College; Doris Kathleen Shuttleworth, Leeds University; Phillip Abd-El-Malik Sika, King's College; Samuel Snelson, Manchester University; and Daisy Coutts Wallace, St. Andrews and Edinburgh Universities.

Botany.—Mark Louis Barst, London Hospital; Thomas Mace Beattie, Leeds University; Solomon Blackman, London Hospital; Nancy Barbara Daniell, University College; Herbert Davies, Birkbeck College; Reginald Norman Downing, London Hospital; Ralph Martin Baland, Bristol University; Ralph Wilfrid Fairfax, King's College; Sophie Elizabeth Hymans-de-Tiel and Violet Ruth Jeffery, Birkbeck College; Evan Thomas Lloyd, Guy's Hospital; Tadmor Ibrahim Makar and Daniell Maximos, King's College; Edmund Philbin, Manchester University; Gerald Richmond Anderson de Montjole Rudolf, King's College; Joseph Solomonoff, London Hospital; and Leslie James Timings, Birmingham University.

At the Second Examination in Anatomy and Physiology held on Sept. 28th and 29th and Oct. 2nd 50 candidates presented themselves, of whom 30 were approved and 20 were rejected. The following are the names and schools of the successful candidates:—

Itamaro Balchruشنا Agaskar, Bombay University and Middlesex Hospital; Frederick Thomas Allen, St. Thomas's Hospital; Maurice Aronsohn, London Hospital; Sidney Thomas Barrett, Cambridge University; Charles Sidney Bluemel, University of Colorado; Moshek Zelmanovitch Bochenek, London Hospital; Gerald Arthur Augustine Bradnack, Guy's Hospital; Percy James Briggs, Cambridge University and Guy's Hospital; Benjamin Young Harper Christmas, Middlesex Hospital; Ignatius Joseph Cruchley, London Hospital; John Griffith Edwards, King's College; Clarence Franklin Eminson, Charing Cross Hospital; Denis Paul Gullfoyle, St. Bartholomew's Hospital; Reginald Jenner-Clarke, London Hospital; Francis William Kemp, Charing Cross Hospital and King's College; John Kendall, Guy's Hospital; Wright Lambert, Middlesex Hospital; Tudor David Llewellyn, University College, Cardiff; Maurice Marcus, London Hospital; Kenneth Mullen, Bombay University and Guy's Hospital; Thomas

Reed, Guy's Hospital; Rowan William Revell, University College; Herbert Leyland Sackett, St. Bartholomew's Hospital; Adolph Sebba, London Hospital; Cecil George Douglas Siggs, Guy's Hospital; Jacques Spira, Brussels University and King's College; Abbas Hilmy Talaat, Middlesex Hospital; Arthur Walford Taylor and Noel Sydney Bailey Vintner, St. Bartholomew's Hospital; and David Hardy Williams, London Hospital.

ROYAL COLLEGE OF SURGEONS OF ENGLAND: LECTURES AND MUSEUM DEMONSTRATIONS.—The demonstrations to be given in the theatre of the Royal College of Surgeons of England in Lincoln's Inn-fields during October will be open not only to practitioners but to medical students and first-aid and ambulance students, dental students being specially invited to attend Mr. Colyer's demonstrations. The course is as follows:—Monday, Oct. 16th, at 5 P.M.: Mr. S. G. Shattock, Wounds and their Repair; Wednesday, Oct. 18th, at 5.30 P.M.: Mr. J. F. Colyer, Fractures of the Jaw; Monday, Oct. 23rd, at 5 P.M.: Mr. S. G. Shattock, Wounds and their Repair; Wednesday, Oct. 25th, at 5.30 P.M.: Mr. J. F. Colyer, Fractures of the Jaw; and Monday, Oct. 30th, at 5 P.M.: Mr. S. G. Shattock, Injuries of Arteries.

In November the first series of a course of lectures on the Anatomy of the Human Body will be delivered by Professor Arthur Keith, Conservator of the Museum, during the afternoons of November, at 5 P.M., in the theatre of the College. This course is intended for first-aid and ambulance students, and is as follows:—Lecture I., Wednesday, Nov. 1st: The Heart and Great Vessels; Lecture II., Friday, Nov. 3rd: The More Common Sites of Hemorrhage; Lecture III., Monday, Nov. 6th: The Lungs and Trachea; Lecture IV., Wednesday, Nov. 8th: Respiration; Lecture V., Friday, Nov. 10th: The Brain; Lecture VI., Monday, Nov. 13th: The Spinal Cord and Nerves; Lecture VII., Wednesday, Nov. 15th: The Structures concerned in Shock; Lecture VIII., Friday, Nov. 17th: The Anatomy of Wounds received in Warfare; Lecture IX., Monday, Nov. 20th: The Structures concerned in the Spread of Infections; Lecture X., Wednesday, Nov. 22nd: The Anatomy of the Ear and Skull; Lecture XI., Friday, Nov. 24th: The More Common Accidents to the Eye and Ear; Lecture XII., Monday, Nov. 27th: The Skin and Mucous Membranes—the more common accidents to which they are exposed. Anatomical preparations and specimens, used for purposes of illustration, will be placed on exhibition in the theatre from 3 to 5 P.M. on each lecture-day. On the following day the same preparations will be placed in the hall of the museum, where they may be studied between the hours of 10 A.M. and 5 P.M.

A second series of lectures will be given in January and February, 1917.

At the First Professional Examination for the Licence in Dental Surgery, held on Sept. 29th and 30th, the following candidates were approved in the undermentioned subjects:—

Mechanical Dentistry and Dental Metallurgy.—Herbert Oliver Holmes and Frederick Laurence King, Guy's Hospital; Cecil Frank Long, Bristol University; John Matley-Moore, Birmingham University; and William Wallace Harold Truscott and Richard Murray Underwood, Guy's Hospital.

Mechanical Dentistry.—Alexander Benjamin Aldred, Arthur Frederick Bartle, and Alan Raymond Cox, Guy's Hospital; Iris Elizabeth Gardiner, National Dental Hospital; Myer Ginsberg, Alwyn Norman Goudge, and Allistair Hyland, Grieve, Guy's Hospital; Thomas Edward Hoggins, Birmingham University; John James, Guy's Hospital; Scholam, Meyerovitch Kropman, London Hospital; Helen Pattie Clara Mayo, National Dental Hospital; Alan Lethaby Morgan, Bristol University; Ernest Albert Nunn and Cornelia Hermanus Olivier, Royal Dental Hospital; William Goodwin Senior, Leeds University; and Stanley Ethelbert Tweney, Guy's Hospital.

Dental Metallurgy.—Christopher Egbert George Busbridge, National Dental Hospital; Lillian Forbes, National Dental Hospital; Hugh Donald Hoggard and Joseph Lauer, Royal Dental Hospital; Margherita Maria Lorez and Mary Jane Ripley, National Dental Hospital; Sidney Stamp, Royal Dental Hospital; Enid Walker, National Dental Hospital; and James Andrew Whittle, Royal Dental Hospital.

At the Preliminary Science Examination for the Licence in Dental Surgery, held on Sept. 26th, 28th, and 29th, the following candidates were approved in the undermentioned subjects:—

Chemistry and Physics.—Gwilym Wynne Griffith, University College, Bangor; and Christoffel Albertus Marais, Guy's Hospital.

Physics.—John William Kewley Cain, Douglas Eastern District Secondary School; Jamshed Bejurjee Chenoy, Royal Dental Hospital; Reginald Gwynne Griffiths and Harold James Lyon, Guy's Hospital; and John Christopher Leslie Phillips, University College, Cardiff.

Chemistry.—William Leslie Cooper Jones, Liverpool University.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates were successful:—

PRIMARY EXAMINATION, PART II.

Anatomy.—H. M. Brown, Guy's Hospital; W. R. Carling, Cambridge and Guy's Hospital; S. M. Cohen, Cardiff; K. M. K. Duff, Guy's Hospital; F. E. Edwards, Manchester; B. E. D. Gray, Guy's Hospital; F. B. Hobbs, Cambridge; T. James, St. Bartholomew's Hospital; T. A. Jordan and J. N. Laing, Manchester; G. L. Levin,

King's College; F. Lyth and H. Lyth, Manchester; S. F. Mahmood, Cardiff; M. Marcus, London Hospital; J. E. B. Morton, Oxford; S. K. Rigg, Bristol; H. N. Schapiro, Guy's Hospital; H. H. Sellm, St. Mary's Hospital; G. M. Trist, Charing Cross and King's College; D. H. Williams, London Hospital; and J. Yates, Manchester.

Physiology.—H. M. Brown, Guy's Hospital; W. R. Carling, Cambridge and Guy's Hospital; S. M. Cohen, Cardiff; K. M. K. Duff, Guy's Hospital; F. E. Edwards, T. A. Jordan, and J. N. Laing, Manchester; G. L. Levin, King's College; F. Lyth, Manchester; S. F. Mahmood, Cardiff; M. Marcus, London Hospital; J. E. B. Morton, Oxford; H. N. Schapiro, Guy's Hospital; T. C. Stephen, Manchester; and D. H. Williams, London Hospital.

UNIVERSITY OF GLASGOW.—At the Fourth Professional Examination for the Degrees of M.B. and Ch.B. the following candidates were successful:—

Joseph Edward Bannen, James Beveridge, Alexander George Brand, Henry Drummond Brown, William Moore Cameron, Allan La Barte Clark, David Clvde, Ann Kelly Cormack, James Orerar, Robert Cunningham, William Donald, George Mundell Hetherington, Arthur Robert Hill, Tom John Honeyman, James Neil Jamieson, Stewart Johnstone, Margaret Jane Thorburn Leitch, Hugh Ernest M'Coll (distinction in Surgery and Clinical Surgery), James MacAllister Mackintosh (distinction in Midwifery), Helen Young Murdock (distinction in Medicine and Clinical Medicine), David Bell Robertson, James Steel, John Stirling, Herbert Watt Torrance, Robert Nisbet Walker, and Alison Edgar Wilson.

Ernest M'Murchie Dunlop, who graduated on July 19th and is now on active service, gains the Brunton Memorial Prize of £10, awarded to the most distinguished graduate in medicine of the year.

KITCHENER NATIONAL MEMORIAL FUND.—A flag day has been fixed for Nov. 7th to be known as "Roll of Honour" Day, and the proceeds are to be devoted to the Lord Kitchener National Memorial Fund. Preparations have already progressed sufficiently throughout the country to justify the council of the fund in anticipating a generous response. The fund, which has for its president Queen Alexandra, has even now accomplished much along the lines on which it was established. It perpetuates the memory of Lord Kitchener in a manner that would assuredly have met with that distinguished soldier's heartiest approval. The main object is to make provision in the time of direst need for officers and men of the Army and Navy who have suffered total disablement. The Council has already dealt with many cases, and wheel-chairs, hand tricycles, special beds, attendants for the paralysed, and means of facilitating locomotion or alleviating suffering have been provided with promptitude, thanks to a generous gift from Mr. Fenwick Harrison of £50,000. The objects which the council has in view are: To equip and endow for all time a home for disabled officers. To establish a permanent fund for relieving disabled officers and men in their own homes. Scholarships are also to be founded for the sons of deceased and disabled officers, and for young men between 18 and 25 who have served with the forces. The organisation is in the hands of Miss C. May Beaman, who will welcome offers of assistance addressed to 10, West Bolton-gardens, London, S.W.

ROYAL VICTORIA HOSPITAL, BELFAST.—Like other charitable institutions, this hospital is faced at present with a rapidly rising expenditure, and an appeal urging the need for increased support has been issued by the board of management. The reasons for this increased expenditure are: increase of patients, the influence of the war (in the rise in price of food, drugs, dressings, &c.), and the greater cost of modern medical and surgical treatment. The cost of coal before the war was about £1000 annually; this year it will amount to almost £3000. Formerly each patient on an average cost little over £60 in the year, now it is more than £80, and the sum is still rising. As it is feared that this year there will be a deficiency of between £4000 and £5000 in the working expenses of the hospital, a strong subcommittee of the board of management has been appointed to look into the matter, and the general feeling is that what is needed is a larger number of annual subscribers, and also more subscriptions from the working classes, who in a great industrial centre like Belfast—whose population now exceeds 400,000—benefits much by such an institution.

THE LATE DR. ALEXANDER BALLANTYNE.—Dr. Alexander Ballantyne, one of the oldest practitioners in Midlothian, passed away at his house, Orfordholme, Gullane, on Oct. 3rd, in his eightieth year. A native of Chorley, Lancs, he had a distinguished career as a student at Edinburgh University, and after graduation he studied at Berlin and Vienna. He then settled down to practise at Dalkeith, and held a large and important practice in that locality for nearly half a century. Dr. Ballantyne was medical officer of health for many years of the Burgh of Dalkeith, and also the visiting physician to the Dalkeith Combination Poorhouse. He was a Fellow of the Royal College of Physicians and had been President of the Obstetrical and Harveian Societies. He was on the commission of the peace for Midlothian. He leaves a widow and two sons; the elder, Mr. John A. Ballantyne, is

resident at Carlisle, and the younger is Dr. Harold S. Ballantyne. In January of last year Dr. Ballantyne's youngest son, Commander Ernest O. Ballantyne, R.N., lost his life when H.M.S. *Viknoe* foundered. Dr. Ballantyne will be much missed by a large circle of friends and members of the profession, by whom he was much esteemed and beloved. An old friend writes: "But it was not merely in his professional line he was appreciated. The personality of his wonderful bonhomie and kindly sympathetic nature brought him friends wherever he showed himself, and no doubt this was one of the secrets of his successful practice, as his cheery smile did as much to stimulate his patients as the best considered of prescriptions. In his private life he had an intense appreciation of music, and his great broad-mindedness and refinement of feeling made his conversation interesting on every subject. In every walk of life which he touched he gained many friends, and his loss is one which will be felt far and wide."

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL.—The two Goldsmid Entrance Exhibitions, offered annually for competition in September, were awarded this year to G. V. W. Anderson, of University College, London, and A. W. Holgate, of Alwyn's School and University College, London.

THE LATE DR. OLIVE CLAYDON.—Miss Olive Claydon, M.D., B.S. Lond., who died at Oldham on Oct. 5th, had an extensive practice there, and was secretary of the Panel Doctors' Association. Outside medicine she took an active part in public life.

GREAT NORTHERN CENTRAL HOSPITAL.—A meeting is to be held in the Mansion House on St. Luke's Day, Wednesday, Oct. 18th, at 3 P.M., on behalf of the Great Northern Central Hospital, Holloway, N., in celebration of the Diamond Jubilee of the institution.

EDINBURGH UNIVERSITY: THE ADMISSION OF WOMEN STUDENTS.—During the last medical session 172 women were attending the extra-mural classes. It is understood that the large majority of these will now take advantage of admission recently granted to the medical classes of the University. No new accommodation needs to be provided at present, as some 500 men students are away serving with the Forces. The University Court is not providing women with facilities for clinical instruction in the coming year, and practical work will, as heretofore, have to be obtained outside the University in the extra-mural school of the Royal Colleges.

ILLEGAL SALE OF COCAINE: HEAVY FINE IMPOSED.—At Bow-street last week two qualified chemists were charged with unlawfully selling cocaine to a man who was found by the police lying unconscious on his bedroom floor in a London hotel. On removal to the Royal Free Hospital the man was found to be suffering from advanced cocaine poisoning. The police discovered three boxes, each of which contained cocaine in tablet form as well as cocaine in solution and a hypodermic needle. No doctor's prescription was found, and the chemist admitted having supplied the drug to an old customer without one. The stipendiary said he had considerable doubt whether he ought not to send the more responsible defendant to prison. He imposed fines of £100, with costs, in the one case, and £10 10s., with costs, in the other.

THE LATE DR. BERNARD SORMANI.—Bernard Sormani, whose death is announced from Amsterdam at the early age of 35 years, had already made his mark in bacteriology and serology. His training was received in the pathological laboratory of Professor Rotgans at Amsterdam, where he began to show the logical understanding and technical skill which were the characteristics of his later work. After his appointment as pathological director of the Onze-lieve-Vrouwe Hospital, he published a paper on a method of determining the quantity of syphilitic antigen in the blood or liquor, and developed this work to a high level. A visit to England made him a keen disciple of Sir Almroth Wright's bacteriotropic methods, and he did original work on the prophylactic vaccination against hay fever, an account of which appeared in *THE LANCET* of Feb. 12th, 1916. His aim to secure the foundation in Amsterdam of an institute akin to that of v. Behring at Marburg was on the road to realisation when his life was cut short by an acute streptococcus infection acquired during his work.

The death occurred at Oxford on Oct. 9th of Mr. Horace Hart, M.A., for many years controller of the Oxford University Press. He was the author of the well-known "Rules for Compositors and Readers," now in its twenty-third edition, originally intended for the staff of the Clarendon Press, but now enjoying much greater publicity.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

CROSS, W. FOSTER, M.R.C.S., L.R.C.P. Lond., has been appointed Senior Administrator of Anæsthetics to St. Bartholomew's Hospital. GALLOWAY, R. P. R., MCILLWAIN, A. L., MOON, C. R. C., NORMAN, J. M., and TYRRELL, J., Resident Physicians to the Royal Infirmary, Edinburgh.

GARRERTSON, W. T., M.D., and HOLBOROW, E. R., M.B., B.S. Lond., Clinical Assistants to the Royal Infirmary, Edinburgh.

HADFIELD, J. A., LAMONT, J. L., MATHEWSON, W. R., MILLER, R. W. N., M.B., Ch.B., STUMP, C. W., and WHITE, H. P. W., M.B., Ch.B. Edin., Resident Surgeons to the Royal Infirmary, Edinburgh.

LITHGOW, J. D., M.B., C.M. Edin., Assistant Surgeon to the Ear and Throat Department of the Royal Infirmary, Edinburgh (re-elected).

SHONE, F. C., L.M.S.S.A. Lond., Certifying Surgeon under the Factory and Workshops Acts for the Walthamstow District of the county of Essex.

THOMAS, Mrs. FRANK, M.B., Ch.B. Edin., has been appointed Supervisor of the Swansea Eye Clinic by the Swansea Education Committee.

Certifying Surgeons under the Factory and Workshop Acts: COAKER, F. W. J., M.R.C.S., L.R.C.P. Lond. (Bromsgrove, Worcester), JACKSON, J. P., M.B., B.S. Durh. (Millom, Cumberland), SIBBALD, B. I. G., M.B., C.M. Edin. (Crewkerne, Somerset), and WILLIAMS, W. M., L.R.C.P. & S. Edin., L.F.P.S. Glasg. (Clwytybont, Carnarvon).

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

When the application of a Belgian medical man would be considered the advertisers are requested to communicate with the Editor.

ASETON-UNDER-LYNE DISTRICT INFIRMARY AND CHILDREN'S HOSPITAL. —Assistant House Surgeon. Salary £120 per annum.

BEDFORD COUNTY HOSPITAL.—Assistant House Surgeon, unmarried. Salary £150 per annum, with board, &c.

BIRMINGHAM, LITTLE BROMWICH FEVER HOSPITAL.—Female Assistant Medical Officer. Salary £300 per annum, with board, &c.

BRISTOL, CLIFTON DISPENSARY, Dowry-square.—Resident Medical Officer. Salary £200 per annum and furnished house.

BRISTOL ROYAL INFIRMARY.—House Physician. Salary at rate of £120 per annum, with board, &c.

CARDIFF, KING EDWARD VII.'S HOSPITAL.—House Surgeon for six months. Also Fourth-year Student Dresser for three months.

Salary at rate of 52 guineas per annum, with board, &c.

DENBIGHSHIRE COUNTY COUNCIL.—Female Assistant Medical Officer of Health. Salary £350 per annum.

DORSET COUNTY COUNCIL EDUCATION COMMITTEE.—School Dentist. Salary £250 per annum.

EWELINA HOSPITAL FOR CHILDREN, Southwark, S.E.—House Physician. Salary at rate of £160 per annum, with board, &c.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—House Physician for six months. Salary 30 guineas.

ITALIAN HOSPITAL.—House Surgeon for six months. Salary £80 per annum, with board, &c.

LEEDS PUBLIC DISPENSARY.—Female Resident Medical Officer. Salary £200 per annum, with board, &c.

LEICESTER ROYAL INFIRMARY.—Pathologist to Infirmary and Venereal Diseases Section. Salary at rate of £400 per annum. Also Medical Officers in Charge of Clinics and Beds. Salary £200 for Male Officer and £150 for Female Officer.

LONDON LOCK HOSPITAL (MALE), Dean-street, Soho, W.—House Surgeon for six months. Salary at rate of £150 per annum.

MANCHESTER ROYAL INFIRMARY CONVALESCENT HOSPITAL, Cheate.—Resident Medical Officer, unmarried. Salary £225 per annum, with board, &c.

MANCHESTER, ST. MARY'S HOSPITALS FOR WOMEN AND CHILDREN.—Resident Surgical Officer. Salary at rate of £150 per annum, with board, &c.

NEWCASTLE-UPON-TYNE, ROYAL VICTORIA INFIRMARY.—Four House Physicians, Four House Surgeons, Accident Room House Surgeon, House Surgeon to Aural and Ophthalmic Departments, House Surgeon to Skin and Gynecological Departments, and House Surgeon to Out-patient Dressing Department.

NOTTINGHAM GENERAL HOSPITAL.—Two House Physicians and One Assistant House Surgeon for six months. Salary at rate of £250 per annum each, with board, &c.

PADINGTON GREEN CHILDREN'S HOSPITAL, W.—House Physician.—House Surgeon for six months. Salary at rate of £80 per annum.

PLYMOUTH BOROUGH.—Assistant Medical Officer of Health. Salary £350 per annum.

PRESTON, LANCAS. COUNTY ASYLUM, Whittingham.—Local Tenens, unmarried. Salary £77s. per week, with board, &c.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.—Assistant Resident Medical Officer for four months. Salary at rate of £80 per annum, with board, &c.

SAMARITAN FREE HOSPITAL FOR WOMEN, Marylebone-road, N.W.—House Surgeon for six months.

SHEFFIELD, ROYAL INFIRMARY.—Two House Surgeons. Salary £100 per annum, with board, &c.

SOUTH LONDON HOSPITAL FOR WOMEN, 103, South Side, Clapham Common, S.W.—Female House Physician and House Surgeon for six months.

SOUTHAMPTON, ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL.—House Physician. Salary £150 per annum, with board, &c.

STAFFORDSHIRE EDUCATION COMMITTEE.—Two Permanent and Four Temporary Female Assistant School Medical Inspectors. Salary £300 per annum.

SUNDERLAND ROYAL INFIRMARY, CHILDREN'S HOSPITAL.—Resident Medical Officer for six months. Salary £150 per annum, with board, &c.

WALSALL AND DISTRICT HOSPITAL.—Assistant House Surgeon and Anaesthetist. Salary £150 per annum, with board, &c.

WEST HAM UNION INFIRMARY, Whipps Cross-road, Leytonstone, N.E.—Resident Assistant Medical Officer for period of the War. Salary £300 per annum, with usual residential allowances.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of a vacancy for a Certifying Surgeon under the Factory and Workshop Acts at Clacton-on-Sea.

Births, Marriages, and Deaths.

BIRTHS.

ADAMS.—Oct. 4th, at Prince's-gate, W., the wife of Surgeon J. Wroth Adams R.N., of a daughter.

CATES.—On Oct. 11th, at Laurel Mount, St. Helens, the wife of Joseph Cates, M.D., D.P.H., of a son.

FINN.—On Oct. 4th, at Blenheim-gardens, Willesden Green, to Allan Finn, M.D., F.R.C.S., Temporary Captain, R.A.M.C., and Mrs. Allan Finn—a daughter.

FORREST.—On Oct. 4th, at Whitwell-road, Southsea, the wife of Fleet-Surgeon J. A. Forrest, of a daughter.

KEIR.—On Oct. 6th, at Beana-cra, Melksham, Wilts, the wife of Captain Ivan Keir, R.A.M.C., of a daughter.

MACFARLANE.—On Oct. 6th, at Pembroke-gardens, W., to the wife of Dr. W. F. Macfarlane, W.A.M.S.—a daughter.

MARRIAGES.

PANTER—SAUNDERS.—Oct. 3rd, at All Souls' Church, South Hampstead, N.W., Surgeon Arthur Edward Panter, R.N., M.R.C.S., to Isobel, only daughter of Mr. and Mrs. William Mill Saunders, Stroyila, Radlett, Herts.

PATERSON—BROTHERSTON.—On Oct. 4th, in Edinburgh, Captain Robert McChayne Paterson, R.A.M.C., to Caroline, third daughter of Robert P. Brotherston, Tynningham, Prestonkirk.

DEATHS.

BOUSTEAD.—On Oct. 8th, at Adelaide-crescent, Hove, Brighton, Lieutenant-Colonel Robinson Boustead, I.M.S., aged 81 years.

BOYD.—On Oct. 6th, at Richmond, John Stewart Boyd, L.R.C.P., L.R.C.S., L.F.P.S.

BROWN.—On Oct. 6th, at Westminster Hospital, S.W., Ralph Brown, M.D., Assistant Medical Superintendent of Bethlem Royal Hospital, S.E., aged 36 years.

CHAWNER.—On Oct. 5th, at Hill House, Clay Cross, Derbyshire, Alfred Chawner, M.R.C.S., L.R.C.P., aged 63 years.

HAMILTON.—On Oct. 7th, suddenly, at Elm House, Hawick, John Rogers Hamilton, M.D., aged 53 years.

INGRAM.—Killed, on or about the night of Sept. 16th, while out searching for wounded in front of the enemy wire, Captain Thomas Lewis Ingram, D.S.O., M.C., R.A.M.C. (attached to King's Shropshire L.I.).

LANGLEY.—On Oct. 3rd, Aaron C. Langley, L.R.C.P., &c., of Cald, Streatham Common North, S.W., in his 71st year.

MACINDOE.—On Oct. 5th, at Morton, Torrington, North Devon, James Gray Macindoe, M.B., late Major, R.A.M.C. (T.) aged 47 years.

MEREDITH.—On Oct. 5th, at Little Massingham Manor, Norfolk, the result of an accident, William Appleton Meredith, J.P., F.R.C.S., in his 69th year.

SWALLOW.—On Oct. 7th, at The Limes, Walthamstow, Norman Heales Swallow, L.D.S., aged 34 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE EVENING STOOL.

To the Editor of THE LANCET.

SIR,—In addition to those adduced by "Personal Experience" in your issue of Oct. 7th, there are other reasons in favour of the evening stool. One is important, especially to bad sleepers. The most favourable bodily condition for sleep is that the upper part of the alimentary canal should be well filled. After food, sleep, is the rule throughout the animal kingdom, and is exemplified in all but those herbivorous animals that, in a state of nature, eat almost continuously. But it is scarcely less important that the lower part of the canal should be empty. Before starting on the perilous course of administering hypnotics, the plan of securing an evacuation in the evening should always be tried. It will often render the administration of hypnotics unnecessary.

I am, Sir, yours faithfully,
CHAS. A. MERCIER.

Oct. 10th, 1916.

To the Editor of THE LANCET.

SIR,—I am glad that "Personal Experience" has called the attention of the readers of your journal (Oct. 7th, p. 663) to this important subject. I have been in the habit of impressing on my patients the necessity of regular evacuations—viz., the first thing in the morning before the bath, which answers two purposes, the washing of the anus and the evacuation of the bowels, and the last thing at night before retiring for the night, so as to have no poisonous matter remaining in the bowels during the night hours.

To refer to another subject mentioned in THE LANCET last week, some time ago I was consulted by a sufferer from angio-neurotic oedema who had been under the treatment of several medical men without relief. The case of "Major, R.A.M.C. (T.F.)," who asked for advice from his fellow practitioners in your columns, appears to be a facsimile of the one I treated successfully. I ordered my patient a brisk purge with a saline mixture, followed up by palatinoids of potassium permanganate to be taken three times a day. After the second day my patient was better, and in a week he was cured and has had no return of the rash.

I am, Sir, yours faithfully,
J. BRINDLEY-JAMES, L.R.C.P.I., M.R.C.S. Eng.
Physician to St. Mary's Training College, Brook Green, W.
Oct. 9th, 1916.

ETYMOLOGY OF THE TERM "BOCHE."

To the Editor of THE LANCET.

SIR,—The suggestion made by Dr. H. Kerr in THE LANCET of Sept. 23rd that the origin of the term "boche" may be the word "botch" or its variant spelling "boche," meaning a "swelling," probably has some foundation. In THE LANCET of Jan. 29th, 1916, on the shape of heads, it is stated that "boche" is slang for "blockhead." They are closely connected; for the "swelling" was the "boss"; in French, "bosse"; in old French "boce"; meaning also a "knob" or "head." Boce and boche are also in Chaucer. By some it is thought to be an abbreviation of French "Caboché" (Latin, Caput), a blockhead. Anyhow, there is strong evidence that it means head or "hard head." Long ago the Germans were called "têtes-carrées," square heads. To name soldiers by their heads and headresses is natural. Cromwell's soldiers were called "Roundheads." "Alboche" has also been used in French. This is no doubt a combination of "Allemand" and "boche." The meaning of "head" clings to the word "boche." The French expression "tête de boche" means "a hard-headed fool"; "a German"; also a "rake" or profligate. (See Dictionary of Argot or French and English Slang by W. von Knoblauch, published by Routledge, London.)

Dr. Kerr suggests that to call a man a "boche" is equivalent to calling him a "bubo." Although this is said by lexicographers to be derived from Greek *Boubon*, the groin, in the old French-English dictionary of Boyer (before 1729) it is spelt "Bobo," and the meaning is a "swelling." This seems more like English "Bob," a knob or swelling, or "cluster"; or it may well be connected closely with Spanish and Portuguese "Bobo," meaning "Blockhead," and English "booby." This will be seen by referring to Diaz's well-known dictionary of the Romance languages; and he suggests that it means "Balbo," which means "stammerer" (Latin—balbutire, to stutter). A "foreigner" in more than one tongue was called either "a dumb man" or "a stutterer" because he could either not speak the home tongue at all or could only stammer it, and therefore he was a "blockhead." It will be seen that this is an alternative explanation to that of imputing the origin of the word to the consideration of the shape of the head.

I am, Sir, yours faithfully,
W.

Sept. 30th, 1916.

ANGIO-NEUROTIC OEDEMA.

To the Editor of THE LANCET.

SIR,—I have read with much interest the letter from "Major, R.A.M.C. (T.F.)," in THE LANCET of Oct. 7th. A similar case came under my notice a few weeks ago. It is obvious these cases are very difficult to treat. Personally I use continuous counter irritation in dealing with such, basing my practice on the theory that the chief underlying cause is microbial. The treatment tends to reduce the number and virulence of micro-organisms in the system. The form I would recommend is multiple superficial acupuncture followed by an irritant, and I should be glad to give your correspondent full particulars.

I am, Sir, yours faithfully,

Bournemouth, Oct. 9th, 1916.

W. J. MIDDLETON.

To the Editor of THE LANCET.

SIR,—In an article by Dr. A. J. Whiting on this subject, published in THE LANCET some three years ago the value of thyroid extract in these cases was pointed out.

There is evidence in the literature of the subject that the treatment has been successful.

I am, Sir, yours faithfully,

Oct. 10th, 1916.

M.R.C.S.

To the Editor of THE LANCET.

SIR,—In answer to the letter of "Major, R.A.M.C. T.F." in your last issue, I suppose that he has tried calcium and intestinal disinfectants.

I had a very obstinate case in private till recently. The patient had severe giant urticaria after any form of exercise or moderate work. This had lasted for years, and numerous medical advisers, general and special, had attempted its cure without any improvement. The patient was advised total abstinence from tea and coffee. The result was instantaneous and complete relief, even after heavy exercise. Cocoa was allowed in moderation.

I am, Sir, yours faithfully,

Oct. 16th, 1916.

R.A.M.C.

THE NEW LIGHTING ORDER.

ACCORDING to the new Lighting Order, which came into force recently in the Metropolitan Police district, lights in London must, from Monday next, Oct. 16th, until the end of the month, be obscured at 5.30 P.M. until one hour before sunrise. The Order applies to the City of London and the whole of the Metropolitan Police district, with the exception of the provisions relating to blinds in railway carriages and lights on vehicles. From Nov. 1st the hour will be 5 P.M.

Digitalis.—The circumstances must indeed be rare in which a hypodermic syringe cannot be sterilised by Wright's simple method. If it is impossible to apply heat it is sufficient to fill the syringe with acid carbolic liq. for 24 hours. Probably most of those who constantly use syringes for injection purposes do not frequently re-sterilise them. A syringe which has been autoclaved when new, and is washed out after use with 1 in 20 carbolic, sterile water, or even freshly drawn tap water, is very unlikely to convey infection. The needle, if of platinum-iridium, can be flamed each time before use. These precautions appear to be sufficient even in bacteriological work. Of course, we are not referring to the use of a syringe for exploration purposes, but assume that nothing but sterile liquid is drawn up into it.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Thursday, Oct. 19th.

DERMATOLOGY (Hon. Secretaries—J. E. R. McDonagh, Henry MacCormac): at 5 P.M.

Exhibition of Cases (at 4.30 P.M.).

Cases and Specimens:

Dr. A. Whitfield: Specimen of Acarus and Run from a Kitten, with Notes on Human Infection derived therefrom.

Dr. Pernet: (1) Sceleroderma; (2) Primary Syphilis of Lip in a Woman.

Dr. H. G. Adamson: Rodent Ulcer of Unusual Type and Distribution.

Friday, Oct. 20th.

ELECTRO-THERAPEUTICS (Hon. Secretaries—E. P. Cumberbatch, Robert Knox).

CLINICAL EVENING (at 8.30 P.M.).

Members who desire to make communications, show cases, or to exhibit instruments, diagrams, &c., are requested to give notice to Dr. Cumberbatch (15, Upper Wimpole-street, W.) immediately.

LONDON DERMATOLOGICAL SOCIETY, St. John's Hospital, 49, Leicester-square, W.C.

TUESDAY.—4.30 P.M., Presidential Address. Cases sent for Consultation.

Demonstration of Pathological Specimens. 5 P.M.

Exhibition of Clinical Cases by Dr. W. K. Stibley, Captain W. Griffith, Dr. J. L. Bunch, Dr. C. Kempster, Mr. C. H. Mills,

and Dr. M. Dockrell.

ROYAL MICROSCOPICAL SOCIETY, 20, Hanover-square, W.

WEDNESDAY.—8 P.M., Paper:—Helen P. Go. drich, D.Sc., and M. Moseley: On Certain Parasites of the Mouth in Cases of Pyorrhea. Exhibition of Specimens of V. Ivocaceae.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, Cavendish-square, W.

FRIDAY.—5.30 P.M., Paper:—Dr. A. Macdonald: The Position of Malaria in Sanitary Administration. Followed by a discussion.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East.

WEDNESDAY—4 P.M., Harveian Oration:—Sir Thomas Barlow.

POST-GRADUATE COLLEGE, West London Hospital, Hammer-smith-road, W.

MONDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simson: Diseases of Women.

TUESDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Dr. Simson: Diseases of Women.

THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Simson: Gynaecological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10.30 A.M., Surgical Out-patients (Mr. E. Gillespie). 2.30 P.M., Medical Out-patients (Dr. T. R. Whipple); Gynaecological Out-patients (Dr. Banister). 3 P.M., Medical In-patients (Dr. E. M. Leslie).

TUESDAY.—2.30 P.M., Surgical Operations (Mr. Carson). Clinics:—Medical Out-patients (Dr. A. G. Auld); Surgical Out-patients (Mr. Howell Evans); Nose, Throat, and Ear Out-patients (Mr. C. H. Hayton). Radiography (Dr. Metcalfe). 3.30 P.M., Medical In-patients (Dr. A. J. Whiting).

WEDNESDAY.—Clinics:—2.30 P.M., Throat Operations (Mr. C. H. Hayton). Children Out-patients (Dr. T. R. Whipple); Eye Out-patients (Mr. R. F. Brooks); Skin Out-patients (Dr. H. W. Barber). 5.30 P.M., Eye Operations (Mr. R. F. Brooks).

THURSDAY.—2.30 P.M., Gynaecological Operations (Dr. A. E. Gilles). Clinics:—Medical Out-patients (Dr. A. J. Whiting); Surgical Out-patients (Mr. Carson); Radiography (Dr. Metcalfe). 3 P.M., Medical In-patients (Dr. E. M. Leslie).

FRIDAY.—2.30 P.M., Surgical Operations (Mr. Howell Evans). Clinics:—Medical Out-patients (Dr. A. G. Auld); Surgical Out-patients (Mr. E. Gillespie); Eye Out-patients (Mr. R. F. Brooks).

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "To THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

Offices: 423, STRAND, LONDON, W.C.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newspapers (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to

THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

Subscribers abroad are particularly requested to note the rates of subscriptions given on page 4.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the rates shown, whatever be the weight of any of the copies so supplied.

Communications, Letters, &c., have been received from—

- A.—Messrs. Allen and Hanbury, Lond.; Ashton-under-Lyne District Infirmary, Secretary of; Ardath Tobacco Co., Lond.; Mr. D. McCrae Aitken, Lond.; Mr. G. C. Atkins, Lond.; Captain C. H. Attenborough, R.A.M.C.; Mr. E. J. Albery, Lond.; Messrs. E. G. Allen and Son, Lond.; Mr. R. Anderson, Leeds; Anglo-American Pharmaceutical Co., Croydon.
- B.—Mr. W. Bryce, Edinburgh; Messrs. T. B. Browne, Lond.; Dr. W. Langdon Brown, Lond.; Dr. A. Bernard, Liverpool; Board of Agriculture and Fisheries, Lond.; Mr. W. F. Bryant, Clifton; Dr. J. Linton Bogle, Derby; Messrs. Butterworth and Co., Lond.; Sir John Byers, Belfast; Messrs. G. R. Brown and Sons, Lond.; Dr. H. W. Bailie, Belfast; Mr. C. Byrne, Lond.; Messrs. Brooke, Bond, and Co., Lond.; Messrs. F. P. Baker and Co., Lond.; Mr. E. Bougault, Paris; Messrs. Furnoughs Wellcome and Co., Lond.; Birmingham City Medical Officer of Health; Lieutenant A. Graham Bryce, R.A.M.C.; Dr. N. W. Buchanan, Peterboro, Ontario.

An Address

ON

THE SPIRIT OF MEDICINE.¹

By J. MITCHELL BRUCE, M.A., LL.D.,
M.D. LOND., F.R.C.P. LOND. & IREL.,

CONSULTING PHYSICIAN TO CHARING CROSS HOSPITAL.

LADIES AND GENTLEMEN.—We have been strangers to each other until to-day (I am addressing myself to students only), but you know that this is not my first appearance at Charing Cross Hospital. When our Dean invited me to address you at the opening of another session I realised that it is fully 40 years since I joined the school, not as a student but as a teacher—but nevertheless a student. Let me say at once to you that I have been a student ever since, and that I am a student still, for I hold that it is never too late to learn; if I might have my time and choice again, I would change places with one of you to-day. The best wish I can offer you is that you all may be ready to say the same yourselves after 40 years of professional life—perhaps from this very place.

It occurred to me to ask ourselves, you and me, how it comes that one can give voice to this sentiment? What is it that attracts us to the study of Medicine—and, once we are engaged in it, binds us so firmly to it? I answer without hesitation—two influences: the Call of Nature and the Call of the Heart.

THE CALL OF NATURE.

The Call of Nature is strong in all of us from the dawn of intelligence. It is as natural for a child, when infancy is past, to ask "Why?" as to cry for food; the one craving is as strong as the other. We are all naturalists at first. Holmes puts this fact plainly when he writes: "From a very early age the child desires to know the why and the wherefore of things and asks innumerable questions which make him the terror and despair of his parents." And let us observe that this inquisitive instinct of the child and boy is a craving for natural knowledge for its own sake, not with an ultimate object; just as he eats because he is hungry without any notion of the physiological use of food. If pressed on the subjects he would give us to understand that both to learn and to eat fill him with a sense of satisfaction and contentment.

In a few years we find the lad an active naturalist with his birds' eggs, butterflies, and silkworms, not to speak of his domestic fauna; or an embryo chemist and physicist building crystals, distilling coal-gas through a "churchwarden" pipe, filling soap-bubbles with tobacco smoke which burst like shells over his younger brother's pasteboard fortifications, leaden soldiers, and tin ships. Other attractions and necessity presently compel the majority of lads to abandon these delights. For the rest there is open a choice to follow one of the applied sciences, as they are called—the practical arts based on natural science. Medicine is one of them, and the young man's father, respecting the bent of his mind and recognising the usefulness and honourable status socially of our profession, where there is also good prospect of a reasonable and independent livelihood if it be honourably practised, confirms his selection of it. It is in this way surely that you have been brought to Charing Cross Hospital to-day—not, I am sure, for purely commercial ends, which it is to be feared have been promoted by the panel.

With his entry as a medical student the young naturalist finds himself in a new world of wonder and delight. Which of us who are your seniors can forget his feelings when he was introduced to the microscope in practical biology and histology; to the demonstrations of physiological actions and chemical physiology; to the delicate coördination and self-regulating mechanisms of the different functions? Even

the structure and the architecture of the dry bones and the associated muscles furnished us with problems of scientific interest. Every day of his years of preliminary study the future physician and surgeon is increasing the range of his knowledge of nature, every day adding to that same sense of satisfaction with knowledge that he felt as a child. I have had friends who spent a few years in the study of Medicine for little or no other purpose than to taste and preserve this feeling. And, indeed, the medical student as long as he is learning of the normal body only may never have occasion, any more than has the child, to put the question directly to himself: "What is the use of all this?"

At the beginning of a more advanced session the answer comes home to him before he has inquired. He is introduced to pathology. He takes up practical morbid anatomy and finds that the delicate cells, the vessels, the viscera that he has learned to know in their intimate structure and uses, the blood in its different elements, the mechanisms which he has studied at work, may and do become disordered and diseased—structurally changed, functionally disabled. In many instances, particularly when he is introduced to bacteriology, he discovers the agents of disease side by side with the morbid changes. He has been no stranger to illness in everyday life, but he gets a shock when he sees these visible and tangible evidences of damage before his eyes. But the instinct of building—of mending, which Holmes names the constructive instinct of every young person, possesses him and gives him heart. He bethinks himself of what he has learned side by side with physiology—something of pharmacology, the local and general actions of drugs on cells, vessels, and nervous and other tissues; and he wonders whether these could not be employed to help Nature in her need, by moderating or arresting disease. Are repair and recuperation of functions possible? With specimens of disease before him he may well question how far the value of artificial interference extends. It is at this stage of his work that another aspect of pathology is revealed to him: a fresh conception of disease is framed in his mind. He is taught to look again and to consider well, and he finds that a great part of what he has been regarding as a morbid or destructive change of the tissues is itself repair, healing. Nature has been mending on her own account—spontaneously, and this in many ways and in many forms. And now the student has reached a position as a naturalist which enables him to comprehend one of the great laws of Nature. He has before his eyes evidence of the Struggle for Existence between the body of man and the countless influences of possible damage that surround and threaten it. He comes to understand what is meant by the Survival of the Fittest: what we signify when we speak of the evolution of life and living things by vicissitude and trial. He learns that there is no such state as rest in Nature: that life is essentially movement and change; and that it is by this struggle that the progress of man is assured—progress towards a destiny that is obscure and still remote in the clash of the many and various influences, favourable and unfavourable, in his environment.

This conception of life and disease opens up to him a new and vast field of nature study. He must acquaint himself not only with microbic agents of pathological change, but with mineral, vegetable, and animal poisons; with foods; with the actions on the body of cold, heat, weather, seasons, and climate; of physical stress on muscles, heart and lungs; and of occupation and exercise. These influences lie outside man, yet constantly affect him; indeed, threaten his health and life; and with them the future practitioner must be familiar. Consider, in passing, the delight and satisfaction of the intelligent mind that is furnished—even if it be but moderately furnished—with such knowledge. Compare the pleasures of life to him with those enjoyed by the laity or even by the lawyer or the lawyer-politician, who is understood in these days to know nothing about science.

With this sense of the relation of man to his environment it comes as an inspiration to the student that he will presently have to take a position, a stand in life, between the one and the other; to do nothing less than regulate, check, neutralise, moderate or interrupt, on the one hand, or on the other hand to utilise, as circumstances may demand, the impact of the one on the other. He will have to

¹ Delivered to the students of Charing Cross Hospital Medical College (University of London) at the opening of the winter session of 1916.

help his individual patients in the struggle for existence, to keep or to make them fit for survival. And by doing so and otherwise (grander purpose of his work still) to promote in however small degree the material evolution of the race. All of which knowledge and intelligent endeavour are those of an earnest naturalist—responding to the Call of Nature. At Charing Cross you have before you as your model the memory of one who was not only among the greatest of English naturalists of his own or other time, but the champion of the doctrine of evolution in its delicate infancy—Huxley, who sat like one of yourselves a student here at the opening of the session on Oct. 1st, 1842. You cannot all be Huxleys, but you can all strive in the many opportunities which Medicine will afford you (for every case of illness is a problem in natural science, and presents some difficulty which it is a delight to overcome) to maintain the reputation which he left behind him and to the school.

THE CALL OF THE HEART.

In time the medical curriculum will have introduced the student to the out-patient room of the hospital—to disease in being, to sickness, suffering, disablement, and misery, variously expressed and variously borne. And now the call of humanity is at his heart. Each case is an occasion for sympathy, an opportunity to help, to benefit—that is, to do good. This motive is quite other than the stimulus that is provided by the study of Nature; it is as strong and active in the unprofessional and the ignorant. But as clinical training proceeds it converges with that other and fits in, merges with it, quickening and sustaining it, and with it constituting the Spirit or Soul of Medicine.

Your sympathy with your patient in distress rouses in you a fresh interest in disease. It prompts you to inquire in a new and necessary direction—into the causes of the patient's illness. Here your taste, training, and equipment for exact investigation will find almost unlimited scope for exercise. This new subject involves nothing less than an inquiry into the man's personal history—his whole record, to trace if possible the relation of his constitution, his bodily soundness or its unsoundness, and in particular the relation of his present illness, to his inheritance, up-bringing, occupation, to his disposition, his habits of living and exercise, his fortunes and his misfortunes past and present. The field of your sympathy enlarges as your investigation of his case becomes more and more intimate; your heart is touched as much by the causes of his disease as by his bodily sufferings; by the history of misfortune, poverty, and misery that led on to illness; and even his indiscretions and follies will be regarded in a new light. For you find that you are studying in concrete form, in the living man, an instance of the struggle for existence. You feel that other than material influences and micro-organisms are among the agents of disease, degeneration and death, and that in your combat with these you will have to reckon with worry, poverty, misery, and men's evil passions.

This consideration enables us to recognise our professional ideal on its highest planes. Why may we not, by standing between this man and the unfortunate circumstances of his life that have landed him in bodily disease and social disability, and by throwing our sympathy as well as our cultivated knowledge into the struggle, promote his moral as well as his bodily welfare, and help him to recover his character as well as his health? The family doctor has constant opportunities special to his professional relations—by organised charity, by personal devotion, by advice, by warning, by reproof, as the case may demand, to help the man to choose the better part. And, as a higher aim still, why may we not by investigation and determination of the effects of moral as well as of material influences on the health, fitness, success and character of mankind in general promote the spiritual evolution of the Race? In this Medicine takes its share with the other professions, and with all, professional and unprofessional, the statesman, the schoolmaster, the parson, who have the welfare of the people at heart. This is humanity indeed. For there is at work on the earth a moral evolution of man as surely as a material or bodily evolution—slow indeed, and at times apparently interrupted or ended according to our imperfect notions of time. This world of ours is a place of trial, of temptation, of probation, of

receiving and accounting for talents and opportunities. We are blessed with a power of self-control manifested in our will, a power of choosing between right and wrong, of overcoming evil influences around us, as surely as we are provided with natural resistance to meet physical forces, dangerous extremes of temperature, and infectious organisms—

"Our wills are ours, we know not how,
Our wills are ours to make them thine."

Here is a prospect! Do not be discouraged by its vastness, its range, and its responsibilities. You will have to take and fill only a small place in it with others. But however small and humble your position in Medicine, if the true Spirit be there, you will be doing what I have called your share. Most likely it will be a general practice among the poor—securing the safe birth and rearing of children; advising on the exercise, training, and occupation of youths; counselling the middle-aged and aged on every subject that bears on their health and through it on their happiness. Or you may choose the service of Public Health, and give your life's work to the same subjects in a collective instead of an individual way. Or, again, the Medical Services of the Navy or the Army or the Colonies may call you; and in what do the duties of these consist but in giving your whole heart, and it may be your life, for others—for their bodily and moral advancement. And this you will do with a sense of humility which well becomes the student of Nature. Having learned so much, you will know how much more remains to be learned; you will know your own ignorance. How can anyone that attempts to appreciate the relation of evolution to time be other than humble over his own contribution to it?

It is a far cry from your entrance at a medical school to eugenics—from the study of bones and the elements of biology and animal chemistry to the practical problems of therapeutics and public health. But I have thought it well to set before you at the start a vision of the ever higher and ever-widening path you will follow, step by step, if you are faithful to the Spirit of Medicine, until you have attained the worthiest object of worldly desire: the betterment of your fellow men. And I have tried to keep this object clearly before you for a reason to which I will now briefly refer as it is apposite to the present time.

Is scientific interest in disease sometimes so strong that it drowns the Call of the Heart? Is it possible that the occasions, opportunities, and urgent need of sympathy are ever disregarded by the profession; that patients become "cases" and cases only? Surely never in this country. Such indifference is cruelty; and we are not cruel. But it is not so everywhere.

I came to Charing Cross from long study in Vienna under German influence in laboratories and in hospitals when the Franco-Prussian War was nearing its end in a German triumph. Investigation and clinical demonstration of disease were pursued in the highly organised order characteristic of the people. But the whole spirit of their institutions was materialistic. The hospital patients were spoken of collectively as *das Material*. And what struck a British-born visitor was both the personal indignities to which certain patients were subjected and the contemptible spirit in which they submitted to them. An English man or woman would have revolted against such treatment, at whatever cost to health and recovery. Already in those days the sense of humanity in the German appeared to be blunted. Already there existed in him a degree of that disregard for the happiness of others and for human life which was ready, as General Smuts has said, "to turn science and economic organisation into instruments of wrong, crime, and ruthless disregard of common morality and Christianity," and which, fed upon worldly success, has developed into his cold-blooded ferocity of to-day. For it would appear that it was not alone excess of scientific interest that made the German surgeon indifferent to the amenities and even the decencies of practice. The German is essentially rude and cruel.

Back in my own country I found that the good name of Charing Cross Hospital rested not alone on the fame of Huxley, its great scientist, scholar and naturalist but on the records of the many old pupils who had given the best of their lives to their patients; and that, outstanding among these, never forgotten and much honoured, were Livingstone,

naturalist and explorer, as well as medical missionary, and thus a link with Huxley; and Llewellyn, who refused to leave his patients at the sinking of the *Alabama* and went down with them and the ship. Here is a noble instance of loyalty to the Call of the Heart! It stands out, no doubt, in part because the occasion was historical, and Llewellyn's devotion to principle suddenly tried and instantly proved. But those noble soldiers just named by the Dean whom from to-day you are proud to call fellow students, and your teachers at the different fronts, physicians and surgeons of the hospital, whom I am proud to reckon among my intimate friends and colleagues, have been and are as faithful to duty in the present war. If we may not pray, as some teach, for success of the Armies of either side, at least we may pray for those friends and others whose purpose is the saving, not the taking, of life. And, apart from such abnormal times, let me tell you that the hundreds of Charing Cross men in general practice whom I have known have by their self-sacrifice in social circumstances almost as taxing as war—in their whole lives spent in the midst of poverty and misery and disease—proved just as loyal to the highest ideals of the profession. Many of you have before you in practice trials of every kind and degree (they are inseparable from professional work)—anxieties, disappointments, vexations, temptations in your weariness to do less than your duty, ingratitude; not to speak of dangers to health, soundness and usefulness, and life. Meet such trials by preserving in your dealings with patients the true balance of head and heart. What I have tried to present to you I will sum up and again commend to you in words which at an early stage of my own professional career I had the good fortune to hear fall from the lips of Sir James Paget: "He that will seek the Truth earnestly, with patience and humility, in the fear of God and the love of man will surely find it."

SOME OBSERVATIONS ON DYSENTERY.

By WILLIAM MAGNER, M.B. R.U.I., D.P.H.,

EX-LIEUTENANT, R.A.M.C.; DEMONSTRATOR OF PATHOLOGY AND BACTERIOLOGY, UNIVERSITY COLLEGE, CORK; HONORARY PATHOLOGIST, NORTH INFIRMARY, CORK.

A DETAILED account of the intestinal lesions would be out of place in this paper. For an excellent description the reader is referred to Castellani and Chalmers's "Manual of Tropical Medicine." It appears, however, necessary to emphasise certain facts with regard to the pathology of the disease.

(A) From the pathological aspect the disease can be divided into two more or less distinct stages. The first is that of uncomplicated entamoebic activity, the second of combined action of the entamoebæ and bacteria.

Appearance of large intestine in early stages.—At this period we are confronted with the results of the invasion of the submucous and muscular coats of the large intestine by the *E. histolytica*. The appearance of the intestine is characteristic. Projecting from the mucous membrane over the affected area are numerous nodules about the size of a small pea. These are usually surrounded by a ring of dilated vessels and are produced as the result of the localised serous exudate around the invading parasites. Some of the nodules are capped by a little dark-coloured slough, and in many this slough will have been cast off so that the nodule is transformed into a small ulcer. These ulcers are of varying depth; some involve the mucous membrane alone, others extend into the submucous and still others into the muscular coat, occasionally even reaching the peritoneum. At this stage the ulcers are flask-shaped, the opening being small and the mucous membrane undermined to a considerable extent. The areas of mucous membrane lying between these nodules and ulcers are normal in appearance. Microscopical examination shows that the primary exudation around the entamoebæ is mainly serous in character. When ulceration has taken place it changes in type, becoming more cellular, but leucocytic accumulation is never a prominent feature at this stage. The blood-vessels in and around the affected area are dilated, but it is rare to see any signs of interstitial hæmorrhage. Entamoebæ

can usually be detected in the depths of the submucous coat. The tissue cells show degenerative changes, chiefly vacuolation.

Clinical features in early stages.—This stage of the disease is characteristically apyrexial. Acute cases are met with in which pyrexia is a feature from the onset of the disease, but these are exceptional. The stools are scanty and gelatinous, consisting entirely of blood and mucus, with no fecal admixture.

Appearance of intestine in later stages.—The characteristic feature of this period is a secondary bacterial invasion of the originally amoebic ulcers. These extend rapidly and become very irregular in outline, the mucous membrane of the affected portion of the bowel becomes uniformly inflamed, and the picture may become almost indistinguishable from that seen in a severe case of bacillary dysentery. As a rule, however, it is possible to determine the origin of the lesions from the persistence of the characteristic amoebic ulcers here and there, usually in the cæcum, and from the fact that the diphtheroid membrane so characteristic of the latter disease is not a prominent feature. The microscopic picture has by this time considerably altered. The blood-vessels are markedly dilated, there is a dense accumulation of leucocytes, and small hæmorrhages can be detected in the mucous, submucous, and occasionally in the muscular coat. The extent of this secondary infection is variable. Occasionally post-mortem examination of the intestine shows numerous fully formed amoebic ulcers with no sign of bacterial invasion having occurred. Usually, however, its effects are to be seen, and in the majority of cases the characteristic lesions are well marked.

Clinical features in later stages.—The bacterial invasion of the intestine wall leads to a change in the clinical picture. The disease, characteristically apyrexial in its earlier stages, becomes pyrexial, and the stools may change in type, becoming more abundant and fluid.

It is quite clear that bacteria must play a very important part in the majority of cases of amoebic dysentery, as it is obvious that the deeper tissues of the intestinal wall become exposed to the action of bacterial agents just as soon as an ulcer is formed at any spot. The pathological and clinical manifestation resulting will, however, depend upon the capability for virulence possessed by the organisms in question. It is not uncommon to find a picture of uncomplicated entamoebic activity even in patients dying at a somewhat advanced stage of the disease. Usually, however, even when death occurs early, the characteristic bacterial lesions will be found either at one or other spot or more or less uniformly over large areas of the intestinal wall.

(B) The pyrexia so frequently observed in the later stages of amoebic dysentery is usually a toxic phenomenon, due to bacterial activity in the gut wall. It is moderate in degree and of the usual hectic type. Occasionally, however, the temperature is maintained at a comparatively high level, and hæmoculture in such cases frequently shows the presence of a bacillæmia. This is attributable to the bacterial invasion of the deeper tissues of the intestinal wall through the ulcerated surface. Organisms growing in such surroundings may, even if normally saprophytic, become sufficiently enhanced in virulence to enable them to penetrate into the blood stream. A series of 30 blood cultures carried out on patients with maintained pyrexia gave, regardless of those cases in which a coexistent paratyphoid infection was demonstrated, three positive results. The clinical features of these cases, with an account of the organism isolated, are included in the following notes:—

CASE 1.—Private, aged 19. Patient admitted to hospital with a temperature of 102° F., which, with a morning remission to 101°, persisted for three days. Bowel motions averaged nine in the 24 hours, consisted of blood and mucus, and contained *E. histolytica*. Hæmo-culture on the third day yielded *B. coli communis*. On the morning of the fourth day the temperature sank to 99°, and the patient made an uninterrupted recovery.

CASE 2.—Sergeant, aged 21. In this case the temperature was of a hectic type, rising to 102° F. at night and falling to normal in the morning. History of severe dysentery with passage of blood and mucus. From date of admission the bowel motions averaged five to nine in the 24 hours, were feculent in character, containing mucus but no blood. *E. histolytica* present. Hæmo-culture on the third

day yielded an unidentified bacillus with the following characters.

Morphology.—Actively motile, Gram-negative, non-sporing bacillus.

Cultural reactions.—Does not liquefy gelatin, produces acid in glucose. No change in lactose, mannite, dulcitol, saccharose, or maltose. Slight pellicle in peptone water; no indol.

Agglutination reactions.—Very feeble clumping with patient's serum in a dilution of 1 in 50 in 12 hours. Not clumped by anti-dysenteric, typhoid, or paratyphoid sera.

Pathogenicity.—The organism is non-pathogenic to guinea-pigs by intraperitoneal injection, the animal recovering after a few days' illness.

This organism has been encountered on several occasions in dysenteric stools.

In this case the pyrexia lasted for 10 days, after which the patient gradually recovered. The remaining case which yielded a positive result was a case of bacillary dysentery, and will be referred to under that heading.

(C) A point of extreme practical importance is the comparative frequency with which amœbic ulcers are detected in the cæcum of patients who have never complained of dysenteric symptoms. In the series of post-mortem examinations performed by Lieutenant Bartlett in No. 21 General Hospital the condition was not infrequently detected in patients dying from gunshot wounds or other causes. These latent cases constitute a serious problem, not only because the disease may at any time become active, but because each such case is a possible source of infection to others.

Parasitology of Amœbic Dysentery.

During the examination of a series of dysenteric stools two types of entamœbæ will be met with, *Entamœba histolytica* and *Entamœba coli*, the former highly pathogenic, the latter harmless. It requires considerable experience to differentiate the two types in the unencysted stage; when encysted the appearance of each is characteristic. Examination of the stool immediately after it has been passed is the ideal procedure, the characteristic movements of the parasite facilitating its detection. When the stool cools the amœboid movements cease, and it therefore becomes more difficult to find the organism. In doubtful cases it is necessary to stain films, and this is always advisable for exact study. The characteristics of the two entamœbæ may be briefly set out as follows.

***Entamœba histolytica.*—Free form.**—Size varies much (15 μ to 60 μ). The ectoplasm is well differentiated from the endoplasm. The protoplasm is finely reticulated, giving the appearance of minute granules. There are usually one or two vacuoles, but occasionally vacuolation may be very marked. The parasite is actively phagocytic, and is frequently seen to contain red blood corpuscles, pus cells, &c. This is a characteristic feature. Amœboid movements are active in comparison with those of *E. coli*. The nucleus is small and vesicular in type, its chromatin being arranged around the inner surface of the nuclear membrane in fine granules or bars. There is usually a well-marked central karyosome, showing in well-stained specimens a minute centriole. Previous to encystment the entamœbæ become much reduced in size (10 to 15 μ). At this stage the protoplasm is frequently seen to contain deeply stained bodies of a chromatinic nature known as "chromidia." These chromidia are characteristic. I have never seen them in *E. coli*, though other observers have described their occurrence in the latter form.

Encysted form.—The encysted form of *E. histolytica* is, from the number of contained nuclei, known as *E. tetragena*. This form was first described by Viereck (1907), who thought he was dealing with a distinct species. James (1914) showed that this form was simply a stage in the life-history of *E. histolytica*. The cyst is exactly spherical in shape, but the cyst wall being very thin, it is apt to become distorted, and may so appear in stained films. The nuclei are characteristically four in number and may be grouped together in the centre of the cyst or arranged in pairs at opposite poles. The "chromidia" described as occurring in the free forms are also frequently observed in the cyst. Cysts containing one, two, or three nuclei may also be met with; these latter forms often show vacuolation of the protoplasm.

Entamœba minuta.—Elmarsian in 1909 observed very minute entamœbæ in dysenteric stools and described them as a new species. James, however, concluded that they represented yet another stage in the life-history of *E. histolytica*. This form is found in chronic or convalescent cases, and is an example of the reduction which takes place in the size of *E. histolytica* previous to encystment.

***Entamœba coli.*—Free form.**—Averages 15 μ to 60 μ diameter. The differentiation between ectoplasm and endoplasm is not clear. Vacuolation is usually a very marked feature. Its phagocytic powers, as compared with those of *E. histolytica*, are apparently weak. It is quite usual for bacteria to be ingested, but I have never seen contained leucocytes or red cells. Amœboid movements are very sluggish. This nucleus differs from that of *E. histolytica* inasmuch as it is considerably larger, and the peripheral chromatin masses are larger and stain more intensely. "Chromidia" I have never seen either in the free or encysted forms.

Encysted form.—The cyst of *E. coli* is larger than the tetragena cyst (averages 15 μ to 20 μ in diameter). The limiting membrane is thicker. The fully developed cyst contains eight nuclei, but forms with two, four, and six nuclei also occur. Differentiation from the tetragena cyst is usually very easy.

Treatment of Amœbic Dysentery.

The stage reached by the destructive process in a given case of amœbic dysentery depends upon the promptness and efficiency of the treatment. Administration of emetine brings about death of the entamœbæ and a more or less rapid recovery depending upon the extent to which the intestinal wall has suffered. In certain very acute or neglected cases the colon becomes irretrievably damaged and the patient's recuperative powers so lowered that a fatal result ensues in spite of specific treatment.

It cannot be too strongly urged that as soon as amœbic dysentery is diagnosed, or even if there is any suspicion of the case being of this nature, treatment with emetine should be commenced and a full course given. Partial treatment is highly dangerous. It has been pointed out by Captain J. G. Thomson, R.A.M.C., that the administration of one or two grains of emetine, though destroying the majority of the amœbæ so that they can with difficulty be detected in the stools, frequently leaves a number of the parasites intact, and these living in the intestinal wall not only prevent healing but give rise to the discharge of cysts and the spread of the disease.

In all cases of amœbic dysentery a full course of treatment should be given. This consists of the administration of $\frac{1}{2}$ grain of emetine subcutaneously twice daily for at least 10 to 12 days. Further observations may possibly show that even more emetine ought to be given. By this means, and this means only, can the patient be safeguarded from relapses and the spread of the disease prevented.

Prevention of Amœbic Dysentery.

Amœbic dysentery is spread through the agency of the cysts of *E. histolytica*. These are never passed in the acute stages of the disease, but may exist in enormous numbers in stools of chronic or convalescent cases. This is a point of extreme practical importance and indicates the necessity for vigorous treatment of all cases. The cysts are, of course, developed from the free forms; emetine destroys the latter, but appears to have no effect on the cysts. If, therefore, sufficient emetine be given to ensure the destruction of all the free forms cyst production is prevented. On the other hand, if the course of treatment be cut short a number of entamœbæ will infallibly escape, and the patient not only becomes liable to relapses but is a danger to the community.

The cysts reach the alimentary canal by means of food infected through the agency of dirt or flies. In this connexion Captain J. G. Thomson has demonstrated the highly important fact that cysts can be detected in the intestinal canal and faeces of flies 18 hours after they have been fed on infective material. Apparently cysts can also live in a fluid medium, such as water or milk, in the absence of a heavy bacterial contamination. It is evident therefore that the prevention of amœbic dysentery amongst the troops depends upon: (1) The elimination of cyst carriers. This

may be attained by early diagnosis and prompt treatment. (2) Efficient protection of food from dust and flies. (3) Efficient and carefully supervised sanitary arrangements in the trenches and in camps. Promiscuous pollution of the soil must be avoided at all costs, and all faecal matter must be rapidly and completely destroyed so as to prevent access of flies.

Observations on the Pathology of Bacillary Dysentery.

An excellent account of the morbid anatomy of this disease is contained in Castellani and Chalmers's "Manual of Tropical Medicine." It seems to me, however, that certain points with regard to the production of the intestinal lesions require emphasis.

(A) In amoebic dysentery the primary lesions result from the entrance of the parasite into the submucous tissues at numerous points throughout the colon. Necrosis of tissue is at this stage limited to foci corresponding to the seats of entamoebic activity. In bacillary dysentery the course of events is radically different. The ulceration does not spread from scattered foci in the gut wall, but is the result of the action of a bacterial toxin which exerts its effects uniformly throughout the affected portion of the bowel. The picture of isolated ulcers separated by areas of healthy mucous membrane, which is so typical of amoebic dysentery, is never found.

(B) Microscopical examination of suitable specimens shows that the earliest pathological change is dilatation of the blood-vessels throughout the intestinal wall and a marked exudation into the submucous coat. This exudation is not, as usually described, serous in character, but is sero-haemorrhagic. In other words, while the submucous layer is markedly oedematous numerous haemorrhages are to be seen throughout its substance. *This submucous haemorrhage is invariably well marked and is highly characteristic of bacillary dysentery.* The dilation of the vessels mainly affects the veins and is not limited to the submucous coat. The subserous veins are also dilated, and the mucosal vessels are in a similar condition. A prominent feature at this stage is the absence of leucocytes. Later, when sloughing of the mucous membrane starts, these begin to accumulate and the vessels will be seen to contain numerous polymorphonuclear leucocytes which are undergoing diapedesis into the tissues.

(C) The ulcers produced in this disease are typically shallow and irregular; they may be very extensive and sloughs visible to the naked eye may be discharged in the stools. Ulceration may extend deeply into the coats of the intestine so as to involve the submucous and muscular coats, but in my experience this is exceptional. The islands of mucous membrane between the ulcers are oedematous and haemorrhagic, and are usually covered by a ragged diphtheroid membrane. Section of the intestinal wall at this stage frequently shows an extraordinary degree of activity in the phagocytes, especially in the large mononuclear varieties. Many of them are seen to be loaded with blood pigment, while it is not uncommon to come across a cell with a contained red corpuscle. The connective tissue cells will be seen in various stages of degeneration, and in this respect vacuolation is a prominent feature, especially in the fibroblasts.

(D) It has been shown that bacterial invasion of the blood stream is an occasional complication in the later stages of amoebic dysentery. That it can also occur in the bacillary form is shown by the following case.

CASE 3.—Corporal, aged 24. Patient admitted to hospital with a temperature of 102° F. History of a week's illness with severe dysenteric symptoms. Stools on admission 4 to 12 in 24 hours, containing fluid mucus and blood. *E. histolytica* absent; *B. dysenteriae* not isolated. Agglutination carried out on the day after admission showed agglutination of Shiga bacillus in a dilution of 1 in 800 in 12 hours. Feeble agglutination of Flexner bacillus in a dilution of 1 in 50 in 12 hours; none in higher dilutions. Haemo-culture on the day after admission yielded a somewhat anomalous bacillus coli which fermented saccharose. On the fourth night the temperature reached 107° and the patient died. Post-mortem examination showed in the large intestine the typical picture of advanced bacillary dysentery, cloudy swelling of liver, spleen, and kidneys, and lobar pneumonia of left lung.

Apart from the bacillæmia, an interesting feature of this case is the high agglutination titre reached by the serum in a

patient who, as far as could be gathered, had been ill only ten days. The pneumonia evidently was the cause of the hyperpyrexia and death.

Observations on the Bacteriology of Dysentery.

An historical review of the work done on this subject would serve no useful purpose and would fill many pages. For an excellent description the reader is referred to Flexner's article in Allbutt's "System of Medicine."

The following notes contain a short account of some organisms commonly encountered in dysenteric stools, with some observations on their pathogenicity. In connexion with this subject I submit the following report on the microscopic and cultural examination of 300 dysenteric stools. The specimens examined were not in any way selected; cultures were prepared whether the disease was clinically amoebic or bacillary, whether entamoebae were or were not detected. The following facts will serve as an introduction to this section.

(A) During the three months September, October, and November, 1915, the dysentery occurring amongst the troops of the Mediterranean Expeditionary Force was almost altogether of the amoebic variety. During this period dysentery bacilli were isolated from only 9 per cent. of the cases examined. From December, 1915, to March, 1916, the total case incidence was much reduced, amoebic dysentery declined and bacillary dysentery became more prominent. Of the cases investigated during this period 20 per cent. were of the bacillary type.

(B) The bacillary dysentery never assumed an epidemic type; the cases were sporadic, not limited to any particular area or any particular unit.

(C) A certain number of mixed cases were encountered, showing simultaneous infection with *E. histolytica* and one or other member of the dysentery group of organisms. The following is a summary of the results obtained during the examination of the 300 cases under review.

| | |
|--|-----------|
| <i>E. histolytica</i> the sole pathogenic agent detected in | 36 cases. |
| <i>B. dysenteriae</i> the sole pathogenic agent detected in | 23 " |
| Both <i>E. histolytica</i> and <i>B. dysenteriae</i> detected in... | 8 " |
| <i>B. Morgan</i> No. 1 isolated from | 13 " |
| Streptococci isolated in large numbers from | 10 " |
| <i>B. faecalis alcaligenes</i> isolated from | 8 " |
| Bacilli resembling dysentery group but failing to agglutinate with anti-dysenteric sera isolated from | 15 " |

Of those cases in which neither entamoeba nor dysentery bacilli were detected the majority were almost certainly amoebic in origin. Most of the patients had received emetine prior to admission, and the response to this treatment was sufficient proof of the nature of the disease, though entamoebae could not be detected in the stools. A feature of almost all the stools examined was the large number of non-lactose-fermenting organisms developing on MacConkey plates. The majority of these are certainly to be regarded as harmless saprophytes developing luxuriantly in a suitable environment.

Bacillus dysenteriae.—Organisms of this class were isolated from 31 cases, 19 yielding *B. Shiga* Kruse and 12 yielding organisms of the mannite-fermenting type.

B. Shiga Kruse.—It seems quite clear that this organism shows a slight degree of motility in young broth cultures. As the culture cools the motility disappears, to return after a short stay in the blood-heat incubator. In cultures over 48 hours old it is impossible to detect any movement. The severity of the disease resulting on infection is variable. In the majority of cases it runs a markedly pyrexial course associated with very severe intestinal symptoms; occasionally, however, the pyrexia is slight and the intestinal symptoms mild. The development of specific agglutinins is constant and may reach a high grade (*vide infra*).

Mannite-fermenting type.—Organisms of this class never show distinct motility. Their virulence is variable. Usually the case runs a course indistinguishable from that of *Shiga* infections, but not uncommonly the symptoms are those of a severe diarrhoea without passage of blood and without any pyrexia. It appears certain that these organisms can exist

in the intestines in an avirulent form. In one case an organism of this class was isolated from the stools 17 days before the appearance of dysenteric symptoms. In an actual infection the development of agglutinins is constant. In the above-mentioned case the serum contained no specific agglutinins at the time of isolation of the organism, whereas one week after the appearance of symptoms the sera had attained an agglutinative titre of 1 in 200.

Cases of double infection with *E. histolytica* and dysentery bacilli are invariably severe, showing marked toxic symptoms, frequent bowel motions, and a considerable though somewhat variable degree of pyrexia.

In bacillary dysentery treatment with the specific antiserum, if instituted before the intestine has become extensively ulcerated, yields satisfactory results. A serum of high potency must be employed and prolonged treatment may be necessary.

B. Morgan No. 1.—The cases from which this organism was isolated showed no constant characters, except the presence of a variable degree of pyrexia. In 5 of the cases *E. histolytica* was also present, in 2 *B. dysenteriae* was isolated, and in the remaining 6 neither pathogenic agent could be detected. The experimental infection of animals (per os) tends to show that this organism cannot originate dysenteric lesions. It appears, however, that, in common with other intestinal bacteria, it may attain some importance as a secondary invader of the ulcerated intestinal wall. The agglutination reaction with patients' serum was carried out in 6 cases. In 2 of these a positive result was obtained in a dilution of 1 in 100; the remaining 4 gave completely negative results (*vide infra*).

Streptococci.—The organism was not completely identified, but seemed to be of the ordinary faecalis type, arresting attention from the large number of colonies developing on MacConkey plates. It was chiefly met with in diarrhoeal stools, but also occurred in the discharges from cases of true dysentery. It is probably of no pathogenic importance except perhaps as a secondary invader. This conclusion is supported by its frequent occurrence in typhoidal stools.

B. faecalis aequaligena.—This organism was met with in 8 cases, and in 4 of these was the predominating organism. On three occasions it was tested against the serum of the patient with negative results.

Bacilli resembling the dysentery group in morphology and cultural reactions.—These organisms were met with in 15 cases. They are all Gram-negative, non-motile bacilli, fermenting glucose, mannite, maltose and saccharose, and producing no change in lactose and dulcitol. Agglutination tests with various anti-dysenteric sera, carried out both on isolation and after repeated subculture, invariably gave completely negative results. Similar organisms have been described by other workers (Ledingham and Penfold, Archibald). The former workers think it probable that they are true dysentery bacilli belonging to a group which can only be differentiated by a serum prepared by immunisation with one or more of their number. I cannot subscribe to this opinion for the following reasons: 1. The organisms were met with in combination with *E. histolytica* and *B. dysenteriae* as well as by themselves; they occurred in simple diarrhoeal stools as well as in those from dysenteric patients. 2. Agglutination tests with patients' serum are almost invariably negative; in two cases only was a positive result recorded (*vide infra*). 3. The organisms are not fatal to guinea-pigs by intraperitoneal injection. 4. They have on several occasions been isolated from typhoidal stools. It would seem, therefore, that these organisms are to be regarded as one of the many varieties of saprophytes which flourish luxuriantly in the lumen of the dysenteric intestine.

Unidentified organisms commonly met with in dysentery stools, both amoebic and bacillary.—Organism No. I. (see table) is particularly interesting, as it was on one occasion isolated from the blood (Case 2, amoebic dysentery) and on another from the spleen post mortem. It is non-pathogenic to guinea-pigs. Subcultures were made weekly for several months, but the organism never varied in its character. Organism No. IV. is at first somewhat similar, but no acid is produced in saccharose, and after prolonged incubation a greenish colour developed on agar slopes. It seems, therefore,

to belong to the fluorescens group. Organisms of Types II. and III. are frequently met with. Their sugar reactions frequently vary on subculture; they could not, however, be made to ferment lactose. No. II. was somewhat out of the ordinary inasmuch as it liquefied gelatin. Several of these

| No. | Morphology. | Glucose. | Lactose. | Mannite. | Dulcitol. | Saccharose. | Maltose. | Indol. |
|------|--|----------|----------|----------|-----------|-------------|----------|--------|
| I. | Gram-negative, actively motile bacillus. | A. | — | — | — | — or A.S. | — | ? |
| II. | " | A.G. | — | A.G. | — | A.G. | A.G. | + |
| III. | Gram-negative, motile bacillus. | A.G. | — | A.G. | A.G. | — | A.G. | + |
| IV. | Gram-negative, actively motile bacillus. | A. | — | — | — | — | — | + |

A. = Acid. A.S. = Slightly acid. A.G. = Acid and gas.
— = No change.

Remarks.—Organism No. I.: Not agglutinated by antityphoid serum; pellicle in fluid media. Organisms Nos II. and III.: No clumping with paratyphoid sera. Organism No. IV.: After long subculture greenish pigment; pellicle in fluid media.

organisms have been tested against the serum of dysenteric patients, and the results obtained suggest that though usually purely saprophytic in some cases they may assume a pathogenic rôle as secondary invaders (*vide infra*).

Experimental Dysentery.

The lesions produced in the intestine in bacillary dysentery are recognised; the fact that they are due in all cases to infection with one or other member of the dysentery group of organism may be taken as proved; but the exact manner in which the lesions are produced is not clearly understood. Flexner and Sweet have carried out some important and interesting work on experimental dysentery, as also have Vaillard and Dopfer, Strong and Musgrave, and many others. The conclusions of these workers may be summarised as follows.

Infection by the alimentary canal in man is followed by typical dysentery. In animals negative results are almost invariable; mucous diarrhoea may develop, but never true dysentery. Intraperitoneal injection is rapidly fatal to most animals, but none of the characteristic lesions are present. Intravenous injection causes in the majority of animals death from septicæmia. The most interesting results are obtained from subcutaneous inoculation. In rabbits, cats, dogs, and young pigs this experiment is stated to result in the development of intestinal lesions somewhat comparable to those found in the human subject. The sequence of events in experimental animals seems to be as follows (Flexner): Absorption of the toxins from the site of inoculation, excretion into the small intestine through the bile, re-absorption and final elimination through specialised areas of the intestinal mucosa, the toxins in their passage through the capillaries setting up the characteristic inflammatory lesions.

In a small number of experiments carried out up to date I have failed to produce lesions in any way comparable to those of human dysentery. I find that intraperitoneal injection of the Shiga-Kruse bacillus is fatal to guinea-pigs and rabbits. The peritoneal cavity contains a sanious exudate, but the intestines present none of the characteristic lesions. Subcutaneous injection results in the development of paralytic symptoms and eventually death. Post-mortem examination shows cloudy swelling of the glandular cells through the body, acute nephritis, but in none of my cases were the intestines affected.

Serological Tests in Bacillary Dysentery.

It is frequently stated that the agglutination reaction in dysentery is unreliable, that occasionally agglutinins are not developed as the result of an attack, and that even in positive cases the serum rarely attains a high agglutinative titre. My experience does not entirely bear out these statements. The number of sera examined is not sufficiently large to permit of dogmatic conclusion, but the following report of the work done in this direction may be of interest.

The first step was to obtain the upper normal limit in a series of non-dysenteric cases. For this purpose 20 sera were examined; they were obtained from enteric patients, cases of pure amoebic dysentery, and healthy persons. The following results were obtained with *B. dysenteriae* (Shiga), the macroscopic method being employed and the time limit four hours:—

- 14 gave completely negative results in a dilution of 1 in 50.
- 4 gave distinct agglutination (++) in a dilution of 1 in 50; none in a dilution of 1 in 100.
- 2 gave distinct agglutination (++) in a dilution of 1 in 50 and a trace (+) in a dilution of 1 in 100.

It was therefore decided to discard the 1 in 50 dilution altogether, and to regard distinct agglutination with a 1 in 100 dilution as proof of a past or present infection with Shiga's bacillus. A similar standard was adopted for the mannite-fermenting strains.

Details of tests.—1. The sera of 9 cases of dysentery, in which *B. dysenteriae* (Shiga) had been isolated from the stools, were tested against the laboratory strain of that organism with the following results:—

- 4 gave positive results up to a dilution of 1 in 200.
- 3 " " " " " " 1 in 400.
- 2 " " " " " " 1 in 800.

2. The serum of 7 cases in which *B. dysenteriae* (Flexner) had been isolated from the stools, tested against the laboratory strain of that organism, gave the following results:—

- 2 gave positive results up to a dilution of 1 in 200.
- 2 " " " " " " 1 in 400.
- 2 " " " " " " 1 in 800.
- 1 gave completely negative results.

The stage of the disease at which the above tests were carried out varied considerably, but in each case symptoms had been present longer than one week.

3. The serum from 30 convalescent dysenteric patients was tested against *B. dysenteriae* (Shiga) and *B. dysenteriae* (Flexner) with the following results:—

- 18 gave completely negative results with both organisms.

Considered as negative—

- 2 gave positive results with Shiga bacillus in a dilution not greater than 1 in 50.
- 1 gave positive results with Shiga bacillus in a dilution not greater than 1 in 100 (+).

Considered as positive—

- 4 gave positive results with Shiga bacillus in a dilution not greater than 1 in 400.
- 2 gave positive results with Shiga bacillus in a dilution not greater than 1 in 800.
- 2 gave positive results with Flexner bacillus in a dilution not greater than 1 in 400.
- 1 gave positive results with Flexner bacillus in a dilution not greater than 1 in 800.

4. The sera from 10 cases yielding the "dysentery-like" bacilli already referred to, tested against a similar organism isolated from other patients, gave negative results in 7 cases; in 2 positive results in a dilution of 1 in 50, negative in a dilution of 1 in 100; and in 1 positive result in a dilution of 1 in 100.

5. The sera of 6 patients from whose stools *B. Morgan* No. 1 had been isolated on being tested against that organism yielded negative results in 4 cases, a positive result in a dilution of 1 in 50 in 1 case, and a positive result in a dilution of 1 in 100 in 1 case.

6. The serum of 6 cases from the stools of which *B. faecalis* *alcaligenes* had been isolated, tested against that organism, yielded in all cases negative results.

7. The serum taken from 20 dysenteric patients, irrespective of the type of disease, tested against *B. coli* and organisms Nos. I. and III. described above, gave the following results: 14 gave completely negative results; 1 agglutinated *B. coli* in a dilution of 1 in 100; 3 agglutinated organism No. I. in a dilution of 1 in 100; and 2 agglutinated organism No. III. in a dilution of 1 in 100.

Summary of Conclusions.

1. Both in amoebic and bacillary dysentery secondary invasion of the ulcerated intestinal wall by organisms from the intestinal lumen is an important factor aggravating both the local and general condition. The pyrexia so frequently observed in the later stages of amoebic dysentery is a result

of this secondary invasion, and though usually toxic in origin may be due to bacterial invasion of the blood stream. A similar septicæmia may occur in the bacillary type of the disease.

2. Amoebic dysentery may be latent, the ulcers being confined to the cæcum and producing no symptoms. Apart from the danger of the disease becoming active such cases may act as foci for the spread of the disease.

3. Every case of amoebic dysentery should be treated by the administration of at least 10 grains of emetine. Incomplete treatment may result in the patient becoming a cyst carrier and a danger to the community.

4. The prevention of amoebic dysentery depends upon the elimination of cyst carriers, rapid and complete disposal of faecal matter, and protection of food from dust and flies.

5. In bacillary dysentery the earliest pathological change in the intestinal wall is dilation of the vessels and a marked hemorrhagic exudation into the submucous coat. Leucocytic accumulation is a later phenomenon resulting on necrosis of tissues.

6. Mannite-fermenting dysentery bacilli can exist in the intestine in an avirulent form. The presence of such an organism in the stools loses much of its significance in the absence of a positive Widal reaction.

7. The agglutination reaction in dysentery is a valuable means of differentiating the bacillary type of the disease. In Shiga infections specific agglutinins are invariably present after the first week of the disease. Distinct agglutination with a serum dilution of 1 in 100 is diagnostic.

8. Judging from serological tests it would appear that certain organisms, normally saprophytic, may in both types of dysentery stimulate the production of specific agglutinins as the result of invasion of the ulcerated intestinal wall.

9. The toxins of Shiga's bacillus are highly pathogenic to rabbits. Subcutaneous injection with either living or killed cultures results in the development of paralytic symptoms and death. The characteristic lesions of the human disease cannot be readily reproduced.

My thanks are due to Major A. R. Ferguson, R.A.M.C., officer in charge of the Central Laboratory, for valuable assistance in carrying out this work; also to Captain J. G. Thomson, R.A.M.C., and Lieutenant G. B. Bartlett, R.A.M.C., who supplied me with much of the necessary material.

A SERIES OF MILITARY CASES TREATED BY HYPNOTIC SUGGESTION.

By J. BENNETT TOMBLESON, M.B., B.Ch. OXON.,

LIEUTENANT (LOCAL CAPTAIN), R.A.M.C.

THE following paper gives in tabular form an account of 60 cases treated by hypnotic suggestion. Twenty earlier cases were dealt with in the *Journal of the Royal Army Medical Corps* of May, 1916, and a brief summary of these is given below. It will be seen that the most successful cases are those of shock psychasthenia of all kinds, while cases of hyperthyroidism and neurasthenia also show very good results. The cases speak for themselves and confirm me in the opinion that practically all the cases of war neurasthenia and psychasthenia can be cured and sent back to work if treatment by hypnotic suggestion is used in reasonable time. Prejudice against this form of treatment does not, happily, exist in the minds of more than a very small proportion of the patients, and my experience has led me to think that it is only found in those whose keenness to return to the war area is open to considerable doubt. So far as I have been able to trace them, the cure has been permanent in my cases, and if the same standard of criticism be applied to these cases and to similar cases treated in other ways the utility of hypnotic suggestion will be obvious to any fair-minded critic.

The cases cited in the previous article included: psychasthenia, 6; hyperthyroidism, 6; neurasthenia, 2; Jacksonian epilepsy with functional gait, 1; trench shins, 1; painful amputation scar, finger, 1; pain in foot after frost-bite, 1. In 17 out of the 20 cases somnambulism was induced, while in the other 3 earlier stages only were reached. The results were all most satisfactory, complete cure (for the time being at all events) being attained.

[illegible]

THE LUETIN REACTION IN SYPHILIS.

BY WILLIAM FLETCHER, M.D. CANTAB.,
PATHOLOGIST, INSTITUTE FOR MEDICAL RESEARCH, KUALA LUMPUR,
FEDERATED MALAY STATES.

Noguchi's luetin consists of killed cultures of the *Treponema pallidum* emulsified with the media in which they have been cultivated. The use of this preparation in the diagnosis of syphilis is analogous to that of tuberculin in von Pirquet's test for tuberculosis; that is to say, if it be injected into the skin during certain stages of syphilitic infections it produces a cuti-reaction.

Noguchi's first experiments were made with rabbits artificially infected with syphilis and, led by the encouraging results which he obtained with these animals, he employed his preparation in the detection of the disease in man. He found that, in the majority of normal persons, 24 hours after the injection a small erythematous area appeared at the point of inoculation, which subsided in 48 hours. On the other hand, in the skin of syphilitic persons the injection of luetin frequently produced certain well-defined lesions of which he distinguished the following three forms.

1. *The papular form.*—An indurated papule, 5 to 10 millimetres in diameter, appears in 24 to 48 hours. The papule increases until the fourth or fifth day, after which it subsides gradually and disappears by the end of the second week.

2. *The pustular form.*—The reaction pursues the same course as the papular form until the fifth day, when, instead of becoming smaller, it increases in size, the central portion softens, and a vesicle forms which rapidly becomes pustular. This ruptures, and a scab forms which falls off in a few days. There is a wide range in the intensity of this reaction. Noguchi found that this form occurred almost constantly in tertiary syphilis and also in cases of secondary and hereditary syphilis which had been treated with salvarsan.

3. *The torpid form.*—In rare instances, though no positive result follows the injection during the first ten days, at the end of that time, or after an even longer interval, a pustular reaction occurs.

Noguchi found that in syphilitics the reaction varies according to the stage of the disease and the treatment which the patient has received. In untreated primary and secondary cases the result is generally negative; occasionally there is a papular reaction. In secondary cases treated with salvarsan the result is positive in more than 70 per cent. In tertiary and hereditary cases the reaction is intense and almost constantly positive.

The sample of luetin which was employed in the investigation under consideration was received from Dr. Noguchi on June 13th, 1914. The first injections were made four days later, and the series of inoculations were completed on August 12th.

As a control to the luetin an emulsion was made which consisted of the same constituents as that preparation except that it contained no *treponemata*. It was prepared according to Noguchi's original method. Two per cent. agar-medium was ground up in a mortar and aseptic fluid added until a mixture was obtained which passed readily through a fine hypodermic needle. Carbolic acid was added to the amount of 0.5 per cent. The fluid was put up in glass capsules, each containing 0.5 c.c., and these were heated for one hour at 60° C.

In accordance with Noguchi's instructions, the test was applied in the following manner. The skin of both forearms was rubbed with pledgets of cotton-wool soaked in a solution of lysol. The injections were made, not subcutaneously, but into the superficial layers of the skin, by means of a tuberculin syringe armed with a very fine needle. A successful inoculation raises the epidermis in the form of a flattened papule, whiter than the surrounding skin, very much like a "nettle-sting," and of about the same duration. In each instance about 0.07 c.c. of equal parts of luetin and salt solution were injected into the left forearm and a corresponding amount of the control emulsion into the right.

The patients among whom this investigation was carried out were all Asiatics (chiefly Chinese) of the coolie class. They were inmates of the Federated Malay States Government hospitals, and I am indebted to the medical officers in

charge of these institutions for permitting me to undertake this work in their wards. Two groups of patients were examined: (1) a group of persons who were either under treatment for syphilis or were believed to have suffered from that disease; and (2), as a control to the first, a number of persons suffering from diseases other than syphilis.

TABLE I.—Results of Luetin Reaction in a Group of 130 Syphilitics.

| | | | | | |
|-------------------------------------|------------|-------------|-------|-------------|-------------------------------------|
| Primary (9 cases, 33% positive.) | | Negative 6 | | Positive 3 | Papular 3 Pustular 0 |
| Secondary (42 cases, 57% positive.) | Active ... | Negative 15 | | Positive 21 | Papular 12 Pustular 9 |
| | Latent ... | Negative 3 | | Positive 3 | Papular 2 Pustular 1 |
| Tertiary (73 cases, 70% positive.) | Active ... | Negative 13 | | Positive 34 | Papular 20 Pustular 14 |
| | Latent ... | Negative 9 | | Positive 17 | Papular 6 Pustular 9 Torpid 2 |
| Doubtful (6 cases, 1% positive.) | | Negative 5 | | Positive 1 | Papular 1 Pustular 0 |
| | | Negative 51 | | Positive 79 | |

The results of the test as applied to the first group, which consisted of 130 individuals, are shown in Table I., where it can be seen that in 79 cases the reaction was positive and in 51 it was negative. The proportion of positive results was least in primary syphilis, greater in secondary, and greatest in the tertiary stage of the disease. In primary syphilis 3 out of 9 reacted positively; in the secondary stage, 24 out of 42; and in tertiary syphilis, 51 out of 73.

As is shown in Table I., the most common form of positive reaction was the papular type. This was the case in every stage of syphilis, except the latent tertiary form, in which there were only 6 papular reactions out of 17 positive results. Among these 17 were included two torpid reactions which occurred in a couple of old men from an infirmary. They both denied that they had ever suffered from syphilis, and both of them gave negative Wassermann reactions; one was blind from old ophthalmia, and the other had many scars which looked like the marks of old syphilitic sores. In the first case the reaction appeared on the fourteenth, and in the second on the eleventh, day after the luetin had been inoculated. One of these patients had been tested about a year before with a different sample of luetin, and on that occasion also he gave a torpid reaction.

In the negative cases the marks of both the luetin and the control punctures had disappeared in about 48 hours. In most of the positive cases a small red papule commenced to appear on the third day at the site of the luetin inoculation. This papule increased until the fifth or sixth day, when it was about the size of a pea. In the papular form the lesions subsided gradually and disappeared at the end of the second week. In the pustular form a red areola appeared round the papule and the centre became cyanosed and softened on about the sixth day. On the eleventh or twelfth day the resulting pustule usually ruptured and discharged a curdy, watery fluid, after which it quickly dried up under a scab and left a pigmented patch which gradually faded. In several instances the contents of these pustules were drawn off with an aspirating syringe and inoculated on to agar, but the latter always remained sterile.

In 4 of the secondary and 5 of the tertiary cases there was a reaction at the site of the control inoculation. In 7 instances this reaction was of the papular type, while

TABLE II.—Results of the Wassermann Reaction in 109 Patients belonging to the Syphilitic Group.

| Stage of syphilis. | In agreement with luetin reaction. | Not in agreement with luetin reaction. | |
|--------------------|------------------------------------|--|-------|
| Primary | Positive ... 2 | 4 | = 6 |
| | Negative ... 0 | 1 | = 1 |
| Secondary | Positive ... 19 | 10 | = 29 |
| | Negative ... 2 | 5 | = 7 |
| Tertiary | Positive ... 25 | 10 | = 35 |
| | Negative ... 8 | 23 | = 31 |
| Totals ... | 56 | 53 | = 109 |

at the point where the luetin had been injected there was a pustular reaction. The 2 remaining cases had pustules on both arms, but the pustules on the right (the control) side were smaller, and disappeared sooner than those at the site of the luetin inoculation. Noguchi

observed a similar phenomenon in 5 per cent. of his cases, and he ascribed it to that peculiar hypersensibility of the skin which sometimes occurs in syphilis and which Neisser has called "*Umschimmung*."

In Table II. the results of the Wassermann reaction are compared with those of the luetin test. Seventeen of the patients were not examined by the Wassermann reaction, because blood could not be obtained for the purpose, and in 4 other cases, where the reaction was negative, the diagnosis of syphilis was rather doubtful, so these were excluded. There remained 109 patients, belonging to the group of syphilitics, who were submitted to both the Wassermann and the luetin tests. The results were as follows:—

| | |
|--------------------------------------|----|
| (1) Primary syphilis, 7 cases. | |
| Positive Wassermann reactions | 6 |
| Positive luetin reactions | 3 |
| (2) Secondary syphilis, 36 cases. | |
| Positive Wassermann reactions | 29 |
| Positive luetin reactions | 24 |
| (3) Tertiary syphilis, 66 cases. | |
| Positive Wassermann reactions | 35 |
| Positive luetin reactions | 48 |

In the primary and secondary cases the Wassermann reaction was more frequently positive than the luetin test; but in the tertiary stage of the disease the reverse was the case and, as is shown in Table II., there were 23 cases of tertiary syphilis which gave negative Wassermann but positive luetin reactions.

There was no more agreement in the results of the two reactions than is accounted for by chance; in the series of 109 cases the results were the same in 56 and at variance in 53. This shows that the substance which gives rise to a positive Wassermann reaction is not the same as the substance which causes a positive response to an injection of luetin.

Of the 109 syphilitic cases 99 reacted positively to one or to both of the tests; in the remaining 10 both reactions were negative. As showing the danger of attaching too much weight to the results of these tests when the reactions are negative it may be profitable to consider these 10 cases in some detail. Two of them were in the secondary stage of the disease. One of them, who was suffering from iritis and polyarthritis, stated that he had had a primary sore a year ago. The other had been infected for three months; there was not the slightest doubt about the diagnosis, for he had a typical macular eruption and a healing chancre in which the *Treponema pallidum* was found. The luetin and Wassermann reactions in this case were both negative. The latter was found to be negative on three different occasions; once, 48 hours after an intravenous injection of neosalvarsan. Tested a fourth time, two weeks later, it had become faintly positive.

In the group of tertiary syphilitics there were 8 cases in which both the Wassermann and luetin reactions were negative. In 4 of these 8 only the scars of the disease remained, situated in two instances in the spinal cord with resulting paralysis, and in two upon the surface of the head and body; the process was no longer active and the primary sore dated back some 20 years or more. In all of the 4 remaining cases active lesions were present; 2 had ulcers, 1 a necrosed tibia, and the fourth was suffering from multiple gummata of the long bones. In the last case the diagnosis was beyond dispute. That is to say, in this series of 109 patients examined by the Wassermann and luetin reactions there was at least one case of active secondary syphilis and one case of active tertiary syphilis in which both reactions were negative.

As a control to the results of the luetin reaction in the group of 130 syphilitics, it was necessary to investigate its action on persons who were free from syphilis, and, for this purpose, the test was applied to a second group composed of 82 persons suffering from other diseases. This second group comprised 40 cases of beri-beri, 20 cases of malaria, and 22 of leprosy. Eight of the beri-beri patients, 4 of the malaria patients, and 7 of the lepers either had scars on the penis or gave a history of syphilis. The Wassermann reaction was positive in 4 of the cases of beri-beri, and in 2 of the patients who were suffering from malaria. Of the 22 lepers, 13 gave positive Wassermann reactions, but several of them had been selected for the luetin test on this account. All of the 82 patients in this control group reacted negatively to luetin with the exception of one man with beri-beri who had contracted syphilis ten years before.

It appears, then, that the action of luetin is specific: positive results occur only in syphilis; but in cases of this disease the proportion of positive reactions observed here was much smaller than that obtained by Noguchi.

It may well be that imperfect storage had impaired the reliability of the sample of luetin employed in this investigation. The efficiency of luetin, in the tropics at least, appears to be impaired by keeping. If the preparation could be kept continuously in a refrigerator, as Noguchi recommends, it is possible that this deterioration might be avoided. In a former investigation the specimen of luetin employed was nine months old and had been exposed to varying temperatures on its journey from New York to the Federated Malay States. Noguchi has stated that when luetin is examined under the dark-ground microscope it is seen to contain about 70 dead *T. pallida* in each field, but in this old specimen not more than a tenth of that number could be recognised, and when it was re-examined three months later the number of organisms had become still further reduced. In the present investigation the sample of luetin employed was about one month old when the series of inoculations was commenced, and three months old when it was finished. It contained about 35 *T. pallida* in a field (1/12 objective and No. 6 ocular). It was stored in a refrigerator, except when it was used in country districts; but on its journey through the post, from the Rockefeller Institute to Kuala Lumpur, it must have been exposed to varying temperatures and it appears to have deteriorated. Such sensitiveness to conditions of temperature detracts from the utility of luetin.

Difference of treatment may also have been a factor in producing discrepancy between the results of luetin inoculations here and those obtained by Noguchi in America. As a result of his investigations into the effect of antisyphilitic treatment upon the luetin reaction Noguchi has concluded that: (a) mercurial treatment may bring out the reaction in those cases in which it has not yet become positive, but such treatment has little or no effect upon the reaction when it has once developed; (b) salvarsan acts very powerfully in bringing out the reaction. Its subsequent continued use may eventually cause the reaction to become negative; probably by destroying the spirochaetes and curing the patient.

As the luetin reaction is influenced by treatment it is clear that uniform results will not be obtained in places where there is a great divergence in the lines of treatment adopted. One quarter of the cases investigated by Noguchi had received injections of salvarsan, and a large proportion of the remainder had undergone a thorough course of mercury. The treatment of syphilis on modern lines has not yet been adopted in the Government hospitals of the Federated Malay States; only 6 of the 130 syphilitics examined by means of the luetin reaction had received injections of neosalvarsan, and in only 2 of these cases had the injections been repeated. Six patients had been treated with mercurial inunctions, four with mercury powders and two with injections. The remainder of those who were under treatment had been given small doses of the perchloride of mercury (0.003 to 0.004 gm.) in the form of the liquor hydrargyri perchloridi of the British Pharmacopoeia.

Conclusions.—The results of the luetin test in the group of syphilitics examined in the course of this investigation were not so frequently positive as in the cases examined by Noguchi and other observers in America. This divergence of results is probably due to: (1) the deterioration from storage of the sample of luetin employed here; (2) differences in the methods of treatment in force in the Federated Malay States and the United States respectively. No positive reactions were obtained in persons free from syphilis; they occurred in syphilitics only. The luetin test is so easily carried out that it would be of the greatest use in general practice if one could always decide, from the result of its application, whether a patient were, or were not, free from syphilis. Unfortunately this is not the case, for while a positive reaction is of great significance, a negative result does not exclude syphilis. When performed in conjunction with the Wassermann reaction the luetin test is of great value; in the early stages of syphilis the Wassermann reaction, and in the later stages the luetin reaction, is more constantly positive. In the great majority of instances one or other reaction is positive; but in a given case, even though both reactions be negative, syphilis is not absolutely excluded.

THE SURGICAL USES OF OZONE.

BY GEORGE STOKER, M.R.C.P. IREL., M.R.C.S. ENG.,
MAJOR, ROYAL ARMY MEDICAL CORPS.

THE accompanying tabulated statement of the results of the first 21 cases treated by ozone at the Queen Alexandra Military Hospital cannot be regarded as anything but satisfactory from every standpoint, be it humanitarian, scientific, or economic. The cases were, for the most part, those of cavities and sinuses in the femur and tibia. It is the experience of those who have seen a great deal of war surgery that such cases obstinately resist treatment and are apt to remain unhealed for months and years.

The treatment consists of the application of ozone to the affected parts; it is, therefore, necessary to have an apparatus for generating ozone which shall be portable and easily worked. The one I am accustomed to use is known as Andriolis' ozoniser. It is called into operation by a four-volt battery animating a $\frac{1}{4}$ -inch sparking Rhumkorff coil. The oxygen passes from a cylinder through the ozoniser, and in doing so comes in contact with a metal armature, the effect of this being to transform the oxygen into ozone.

Table of Wounds, Sinuses Treated by Oxygen and Ozone.

| No. | — | Nature of disability. | Pre-vious duration. | Dura-tion of treat-ment. | Result. |

* In this case treatment was discontinued for four weeks.
N.B.—I have only failed in one case, Major S. H. He was twice placed for fracture of the femur. The "plate" acted as a "foreign body."

The properties of ozone, which have a wonderfully healing effect, are, as far as one can say at present, three:—

1. It is a strong stimulant and determines an increased flow of blood to the affected part.

2. It is a germicide, which destroys all hostile micro-organic growth.

3. As the French chemist Hennocque has shown, it has great powers in the formation of oxyhæmoglobin.

The ozone is applied on the wounded surface or to the cavities and sinuses for a maximum time of 15 minutes, or until the surface becomes glazed. Ozone has the particular power of disclosing dead bone, foreign bodies, septic

deposits, &c. This, I believe, it does by destroying the granulations and micro-organic growths (presumably unhealthy) that are found in close contact with septic deposits, foreign bodies, or dead bone.

Cleansing and Dressing.

Wounds and sinuses, &c., are washed twice daily with boiled water and a dressing of dry gauze is applied. It must be observed that at first ozone causes an increase of the discharge of pus; later on the pus is replaced by clear serum, which at a still later stage becomes coloured reddish or pinkish. In open wounds it is necessary to strip off the parchment-like film surrounding the edges, which is composed of oxidised serum. This is easily effected by applying a hot compress for 15 or 20 minutes, after which the film can be easily peeled off with a dissecting forceps.

At present our knowledge of the effects of ozone is but small, but later I hope to bring before the medical public further satisfactory facts with reference to its working and results.

Clinical Notes:**MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.****PLACENTA PRÆVIA AND CÆSAREAN SECTION.**

BY A. G. TRESIDDER, M.D. LOND.,
CAPTAIN, INDIAN MEDICAL SERVICE; STAFF SURGEON, POONA.

ONE meets only a few cases of placenta prævia in which the condition of both mother and child justifies the operation of Cæsarean section. This is more especially so in hospital practice, where such patients are usually admitted in a more or less advanced stage of labour and only after there has been a considerable loss of blood, a state of affairs which would obviously contra-indicate a major operation when other means of delivery are open to us.

In recent years it has been recognised that the best treatment for certain cases of placenta prævia is Cæsarean section, and the results obtained among these carefully selected cases have been very satisfactory both as regards the maternal mortality and that of the infants. The maternal mortality of placenta prævia treated on the ordinary lines is 4 to 8 per cent., and the average foetal mortality is 60 per cent. Munro Kerr says: "The best figures give 4 per cent. and 35 per cent. respectively, and they are as low as one can ever expect to reach with the present recognised methods of treatment." But in certain cases of placenta prævia, such as the one described below, Cæsarean section would, I think, justify us in expecting much better results than a maternal mortality of 4 per cent. and a foetal one of 35 per cent.

As regards the mothers, there seems no special reason why Cæsarean section performed in suitable cases of placenta prævia should not yield quite as good results as it does in cases of contracted pelvis, when the operation is performed under the best conditions, the maternal mortality then being 2.9 per cent. (Amand Routh). Berkeley and Bonney place the maternal death-rate of Cæsarean section, when this operation is performed under the best conditions, as "probably under 1 per cent." In well-selected cases of placenta prævia the maternal mortality should not, therefore, be greater than about 2 per cent., i.e., about half as great as we could expect from any other method of treatment. One other great advantage to the mother is a lesser risk of morbidity as compared with that which results from the necessary manipulations, often prolonged, which accompany delivery *per vias naturales*.

The foetal mortality must obviously be very greatly reduced by Cæsarean section, and the rate of 35 per cent. at the best would be reduced to one of about 5 per cent. Further, in most cases the mother should be as well able to nurse her infant as after normal delivery, a result which, because of some slight sepsis or as the result of hæmorrhage before and during delivery, is often denied to the mother who has been otherwise delivered.

Generally speaking, the operation of Cæsarean section in a case of placenta prævia is indicated under the following

conditions: (1) when the hæmorrhage has not been excessive and the maternal pulse is full and its rate not above 100 per minute; (2) when the cervix is undilated and appears to be unduly rigid, indicating that dilatation is likely to be slow and difficult, as is often the case in elderly primiparæ; (3) when the surgeon can be confident that there is no risk of sepsis from previous frequent vaginal examinations, &c.; (4) the pregnancy should have reached full term or very nearly so, and the foetal heart sounds must be good; (5) another factor which should influence the surgeon in deciding in favour of Cæsarean section is the co-existence of some disproportion between the size of the foetal head and the maternal pelvis; and (6), as in the case here described, when the parents are especially desirous of a live child. The following case will serve to illustrate these points:—

The patient, a Eurasian aged 32, was admitted under my care to the maternity department of the Sassoon Hospital, Poona, on Oct. 19th, 1915. She had been married 12 years, and the present was her first pregnancy. The last period ended on Jan. 11th, 1915; the probable date of confinement would be about Oct. 16th, 1915. The patient stated that she had had slight pains for about 36 hours; bleeding began a few hours before she came to hospital. No vaginal examination had been made previous to her admission to hospital. When I saw her she was having feeble pains at about half-hourly intervals. Her general condition was excellent, the pulse being full and its rate 80 per minute; the face was placid and the tongue clean and moist. On abdominal examination the child was found to be in the first vertex position and the foetal heart sounds were good. The pelvic measurements were normal. On vaginal examination there was still a definite and fairly firm cervix, which admitted one finger only; at the internal os only placental tissue could be reached.

Both the patient and her husband were very desirous of having a live child, and considering all the points of her case, I felt justified in advising abdominal section. Cæsarean section was therefore performed and a full-time live child was delivered. The bleeding from the placental site was somewhat excessive and for a moment rather disconcerting; it was certainly more than I had noted in cases of Cæsarean section in which the placenta was normally implanted. During the first few days after the operation there was a good deal of trouble from after-pains; otherwise the patient made an uneventful recovery, and both mother and child were discharged quite well on Nov. 27th.

My thanks are due to Lieutenant-Colonel A. Hooton, I.M.S., for permission to publish this case.

Poona.

LEFT FALLOPIAN TUBE FOUND IN LEFT FEMORAL HERNIA.

BY E. G. RENNY, M.R.C.S. ENG., L.R.C.P. LOND.,
ASSISTANT SURGEON AND ANÆSTHETIST ESSEX COUNTY
HOSPITAL, COLCHESTER.

I REPORT the following case as I can find no record of a Fallopian tube presenting in a femoral hernia.

The patient, aged 42, married, mother of three children, had noticed a lump in the left groin for 18 months. During the last five weeks it had become painful, and thinking it was a rupture she bought a truss and wore it. The effect of wearing the truss was to make the lump very painful and inflamed. She then asked me to see her. I found a painful swelling in the groin which, on account of the inflammation present, made the diagnosis uncertain. It was dull to percussion, not reducible, and had no impulse on coughing. No strangulation symptoms were present. The finger could be passed up the inguinal canal for a short distance. Rest was advised, and when the inflammation had subsided (on August 17th) I made an incision over the tumour. It proved to be a femoral hernia with somewhat thickened sac. It contained a considerable quantity of green fluid (under tension). Occupying the crural canal was a red, soft substance, which, when traction was made on it, proved to be the left Fallopian tube with its fimbriated extremity presenting. This was returned to the abdomen without much difficulty, and the sac was ligatured and excised.

Colchester.

ERRATUM.—In Mr. Irwin Moore's paper on the Operation of Laryngo-fissure Fig. 2 appears upside-down, giving the anæsthetist's and not the surgeon's view of the field. Mr. Moore points out, also, that Dr. Lack's views are incorrectly stated at the end of the article. Dr. Lack does not hold that impairment of voice would follow as described.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

Exhibition of Specimens.—*Concealed Accidental Hæmorrhage.*—*Acute Toxæmia of Pregnancy.*—*Cæsarean Section and Hysterectomy for Accidental Hæmorrhage.*

A MEETING of this section was held on Oct. 5th, Dr. G. F. BLACKER, the President, being in the chair.

Dr. W. S. A. GRIFFITH showed a Lipoma of the Broad Ligament, weighing 13 lb. At the operation the tumour was found to be retroperitoneal, extending from the right broad ligament to the under surface of the liver. The peritoneal capsule was incised, and the tumour was gradually enucleated from above downwards. The chief vessels were found down in the pelvis, where the tumour had opened up the broad ligament. The cavity thus left was closed by a purse-string suture and the abdomen closed without drainage. The patient made a good recovery. Only two specimens of lipoma of the broad ligament appear to have been hitherto recorded.

Dr. C. HUBERT ROBERTS showed a large Ureteral Calculus, weighing 275 grains. The patient, aged 30, had been in several London hospitals since the age of 17 with symptoms pointing to renal calculus or tuberculosis. The diagnosis of ureteral calculus or calcified gland was made by Dr. Roberts in 1914, when the patient was pregnant. After delivery she was not seen until June 9th, 1916, when she was admitted to the Samaritan Hospital. On laparotomy the right ureter was at once seen, much dilated and thickened, above the stone. The stone was removed, drainage being provided by making an opening in Douglas's pouch through to the vagina. The patient made an uninterrupted recovery.

Dr. ROBERTS (for Mr. FRANK BELBEN) also showed a large Vesical Calculus weighing 3½ oz., formed around a slate pencil, and removed by suprapubic cystotomy from a girl aged 17. A small stone was also present. Some difficulty was encountered, as the bladder was contracted round the large stone and the pencil had ulcerated into the bladder wall. The patient made a good recovery.

Dr. ROBERTS also showed an instrument invented by the late Dr. Wallace, of Liverpool, for opening Douglas's pouch per vaginam during an abdominal operation.

Dr. OUTHBERT LOCKYER showed a series of Calculi: 1. Small calculus removed from upper part of ureter; good recovery. 2. Two calculi removed from lower end of ureter in patient, aged 63, being operated upon for uterine fibroid and solid ovarian tumour. The entire ureter was removed. Convalescence prolonged by formation of perinephric abscess, which was opened and drained. 3. Calculus from a patient from whom Dr. Lockyer had previously removed uterus, part of rectum, and part of vagina for new growth—an adenomyoma.¹ The calculus had formed at the recto-vaginal junction in consequence of a ureteric fistula. It was removed per vaginam. 4. Large calculus 5½ inches in circumference removed from bladder of patient who had a vesico-cervico-vaginal fistula, following difficult labour; calculus was removed during operation for closure of fistula.

Remarks were made by Dr. ROBERTS, Mr. DOUGLAS DREW, and Dr. GRIFFITH.

Dr. A. J. MCNAIR read a short communication on a case of entirely Concealed Accidental Hæmorrhage, with Intraperitoneal Bleeding.

Mr. CARLTON OLDFIELD and Mr. REGINALD HANN related a case of Acute Toxæmia of Pregnancy with Accidental Hæmorrhage, Treated by Cæsarean Hysterectomy; Recovery. It was suggested that accidental hæmorrhage is in some cases, like the one reported, a symptom of pregnancy toxæmia, and the opinion was expressed that in severe cases of accidental hæmorrhage, in which the cervix is closed, the patient should be delivered by Cæsarean section.

Dr. W. FLETCHER SHAW read a paper on Cæsarean Section and Hysterectomy for Accidental Hæmorrhage. In a very few cases of accidental hæmorrhage no method of treatment has the slightest effect upon the uterine muscle, which

¹ Trans. Royal Soc. Med., 1915, viii., No. 5, p. 47.

remains relaxed and allows severe hæmorrhage to continue. Of the six cases described, five were treated by Cæsarean section and the uterus was removed at the same operation; in the sixth case the child was delivered and hysterectomy performed some hours later because of a persistent flow of blood which treatment was powerless to check. These patients were all in a critical condition at the time; three died and three made a good recovery. They were all multiparæ and all had a very large amount of albuminuria. In five there were large hæmatomata in one or both broad ligaments, and in two there was a large quantity of free blood in the peritoneal cavity which had evidently escaped through some abrasions in the peritoneal coat of the uterus. As all these patients had a large amount of albuminuria, which cleared up a few days after delivery, in all probability the toxæmia producing this also produced the hæmorrhage. Dr. Fletcher Shaw emphasised the fact that he advocated this method of treatment only in the very rare cases where the uterine muscle would not contract.

These papers were discussed by Dr. AMAND ROUTH, Dr. HERBERT SPENCER, Dr. H. BRIGGS, Dr. G. F. DARWALL, SMITH, Dr. MUNRO KERR, and Dr. HASTINGS TWEEDY.—Mr. CARLTON OLDFIELD and Dr. FLETCHER SHAW replied.

Reviews and Notices of Books.

Welfare Work: Employers' Experiments for Improving Working Conditions in Factories.

By E. DOROTHEA PROUD, B.A. Adel., First Catherine Helen Spence Scholar. London: G. Bell and Sons, Limited. 1916. Pp. 363. Price 7s. 6d. net.

THIS book belongs to the series of volumes issued under the editorship of the Hon. Pember Reeves, entitled "Studies in Economics and Political Science"; the series consists of monographs by writers connected with the London School of Economics and Political Science. Miss Proud's volume is introduced to the public by Mr. Lloyd George, and the Secretary of State for War points out that of all the changes which the great struggle has brought in its train none is more significant than the revolution in the structure of British industry, indicated by the fact that many private firms of manufacturers have submitted to a general control by the State. Similarly many workers, who would otherwise have been unable to exercise the necessary discretion, have desisted from the endeavour to regulate the supply and restrict the output of labour. These things are noted as most important indications of the change of temper and opinion which has overtaken us all during the great struggle for freedom.

Miss Proud studies welfare work from every standpoint. In the first part of the book factory legislation is considered in its relation to employers and employed, and in discussing the ideals of a welfare worker we find very well described the attitude assumed by many sincere champions of the working class in the presence of welfare workers. Welfare ministrations, it is feared, may sap the resolution of the workers, an easy content being produced, under which individuals become content with their own lot and callous to that of their fellows. As welfare work appears to pay both the employer and the employees, we may expect under its influences a contented community though it be within a discontented State, but we cannot think that any real support of the social instinct comes from the feeling that the right to grumble must be maintained. Miss Proud is in agreement with other social workers in believing that welfare work does not predispose industrial peace and is not incompatible with trades unionism.

In dealing with the relation of work to workers, with industrial environment generally, and with the provision of lavatories, cloakrooms, and rest rooms for the workers, the author is highly informing, and we hope that her words will be widely read. The health of the worker, which is the particular sphere of the welfare department, should be a matter of deep concern to all of us, and in particular it is essential that the health of our women workers should be safeguarded, for women are, as Miss Proud says,—

Habitually less thoughtful than men concerning their own health, and a mixture of mock modesty and ignorance commonly prevents them from consciously considering

themselves as potential mothers. Whatever changes may occur, the health of women workers must needs be of paramount importance to the nation. Their position in industry, even though partially safeguarded by legislation, is still unsatisfactory.

Miss Proud's remarks on wages and hours may not have any great novelty for those who have practical relations with the employment of labour, but the information is put well and justly, and those to whom the organisation of factory work is unknown will be able to read her words with full instruction. Under the heading incidental aids to welfare we come to a part of the book which is of more immediate medical interest; here, in a well-written section, factors that conduce to physical well-being—lodging, food, exercise, baths, and recreation—are considered. The facilities for recreation and social intercourse which are prevalent in various industrial centres are commended, but Miss Proud considers that, broadly speaking, it is well to leave the initiative in these matters to the workers, though the actual organisation has often to be taken out of their hands, the employers not infrequently retaining the control.

A series of appendices illustrate, among other things, the employers' influence on early factory legislation and their experiments in reduction of hours; and the development of a welfare department as seen in an individual outlined case. Specimen menus from factory dining-rooms and examples of printed forms used in various welfare departments help to complete the varied picture of factory life which is drawn in this interesting and competent book.

The Milk Problem in Indian Cities, with Special Reference to Bombay.

By LEMUEL LUCAS JOSHI, B.Sc., M.D., 'Municipal Analyst, Bombay. With a Foreword by JOHN A. TURNER, C.I.E., M.D., D.P.H., Executive Health Officer, Bombay Municipality. Bombay: D. B. Taraporevala, Sons, and Co. 1916. Pp. 232.

WHAT Dr. J. E. Lane-Claypon has done in this country by collecting all the important facts of milk and its hygienic relations Dr. Joshi has done for India, and his book is likely to remain for long the standard work on the subject. In the preface Dr. Turner alludes to the very unsatisfactory state of the milk-supply of the large towns in India which has existed for long enough, but to which attention is only now being turned. The milk, he states, is stored by the *gomlees* or indigenous agencies in dirty hovels, the brass containers are scrubbed with mud obtained from filthy sources, and milk is carried far in open cans with a floating wisp of dirty straw to prevent spilling. He expresses the hope that Dr. Joshi's work will, by placing the information in the hands of the public, enable them to coöperate with the authorities in obtaining better conditions.

The author begins with an account of Indian milch cattle and the milk-supply of Indian cities. An excellent series of plates illustrates the various breeds of cows and some of the conditions of stalling. The chemical composition of milk obtained from various sources follows and the proposed milk standards for India. The bacteriological examination of Bombay milk is then discussed and the adoption of a bacterial standard for India is suggested. The factors affecting the composition and purity of milk are dealt with, and then its relation to the public health, especially in regard to infantile mortality. Finally, remedial measures are given ample space, and are considered under the headings of economic, sanitary, and legislative.

We trust that the book may attract the attention which it merits and be a substantial factor in obtaining much-needed reforms.

European and Other Race Origins.

By HERBERT BRUCE HANNAY. London: Sampson Low, Marston, and Co., Limited. 1916. Pp. 491. Price 21s. net.

THIS is a very difficult book to read; an enormous amount of energy has gone to the making of it, but the huge mass of facts and suppositions which has resulted will not, we fear, attract the attention of any large audience, for readers will be puzzled by the author's method of approaching his subject, as well as by the somewhat indiscriminate and shapeless manner in which huge lumps of knowledge are handed out to them. We are not blaming the author for being obscure now and again or dry in this or that place, for his work is exhaustive, and the subject of race origins

can never be treated as a simple one. Mr. Hannay thinks, indeed, that the epoch we are living in is probably more portentous than any that mankind has yet witnessed, and we agree with him that under the influence of the war intellectual fetishes, before whose shrines learned and unlearned alike have knelt for generations, are, if not "shattered or tottering to their fall," considerably discredited as the collective wisdom of civilisation grows greater. He adds, however, speaking of these fetishes, that "some still command as successfully as of yore the blind unquestioning worship of the Many: for the Hierarchy whose place, power, and prestige depend upon the maintenance of these idols, are still strong—still disdainful of all who dare to whisper to their flocks aught of a creed that undermines or even challenges their own." This example of his style will show how difficult it is to understand exactly what is the meaning which he desires to convey.

The first and second sections of the book deal with the rise and developments of ethnic movements, in which we have the author's views of the origins of the Arabians, Jews, Dutch, and Germans, and the remarks upon the heterogeneous and artificial make-up of the last are historically sound. The third book describes the origins of the Scythians, the Scottish and Welsh, the Angles, Saxons, and Northmen, and various intermediate links in these nationalities. A long list of authors and works is given in support of the close array of statements of which the book is composed, and only thoroughly well-read ethnologists can form a just opinion as to how far the author has digested such masses of information properly and arrived at justifiable conclusions. To a medical audience the work, we think, will not prove very useful, while the many directions in which medicine can be associated with the study of race origins do not appear to have had attraction for the author.

MISCELLANEOUS VOLUMES.

THE increased demand for nursing owing to the war and to an awakening sense of the value of child life has led to much publication, and in the course of recent weeks we have received several books designed to facilitate the teaching of nursing and the related subjects of maternal and child welfare. Among those written for the trained nurse we may mention *Surgical and Gynaecological Nursing*, by EDWARD MASON PARKER, M.D., F.A.C.S., Surgeon to the Providence Hospital, Washington, D.C.; and SCOTT DUDLEY BRECKINRIDGE, M.D., F.A.C.S., Gynaecologist to the same institution. (London and Philadelphia: J. B. Lippincott Company. Pp. 425. Price 10s. 6d. net.) The authors attempt a summary of the procedures in general surgery and gynaecology of a nurse's professional work, and include in her scope a knowledge of infection, its pathology and nomenclature; minor technique, in its relation to posture; bandaging and the keeping of charts and records; the patient's comfort and welfare; and the operation and details of asepsis and instruments. A final section is devoted to the gynaecological dispensary, emergencies, the personal attitude of the nurse, and a useful epitome of some common surgical and gynaecological conditions set out in brief outline. The illustrations are numerous and informative.—*A Text-book of Physics and Chemistry for Nurses*, by A. R. BLISS, Junr., Ph.G., Ph.Ch., A.M., Phm.D., M.D., lecturer on chemistry and materia medica at the Grady Hospital Training School for Nurses, Atlanta; and A. H. OLIVE, A.B., A.M., Ph.Ch., Phm.D., lecturer on chemistry at the Hillman Hospital Training School for Nurses, Birmingham, U.S.A. (same publishers; pp. 239; price 6s. net), is another book from which the nurse may gain an elementary knowledge of science as it affects her work. The matter is necessarily condensed, but those portions of the subject which are of special interest to nurses are conveyed in a manner easy to be understood. The appendix contains a brief but clear exposition of the metric system, and there is a useful glossary.

As Mr. HAROLD CHAPPLE, obstetric surgeon to Guy's Hospital, points out in his Foreword to *A Text-book of Midwifery*, by JANE AITKEN (London: Ash and Company. Pp. 83. Price 1s. net), that in many text-books the facts are so skilfully concealed in a multitude of words that the average nurse or midwife finds it difficult to disentangle them. Miss Aitken's book consists of notes of lectures which she delivered in the capacity of chief midwife to the Nurses' Charity at Guy's Hospital and as superintendent of the District Nurses' Home at Gloucester, and it may well be

used as an aid to intelligent study and to supplement and revise oral instruction.—The training of a nurse in the care of the insane requires special teaching and experience, and in *Mental Nursing* (London: The Scientific Press, Ltd. Pp. 98. Price 2s. 6d. net), Dr. W. H. B. STODDART reprints some lectures from the *Nursing Mirror*, in order to give to a prospective mental nurse some idea of the work he or she contemplates, and to furnish those actually engaged in mental nursing with a practical guide devoid of academic details.—Considerations of ethics are very important for the nurse in her relation to her own kind and to the medical man, and the study should not be neglected during her student period. In *Studies in Ethics for Nurses*, by CHARLOTTE A. AIKENS, formerly superintendent of Columbia Hospital, Pittsburg (London and Philadelphia: W. B. Saunders Company. Pp. 320. Price 7s. 6d. net), we have a text-book which embraces the whole life of the nurse, designed to aid both teachers and students. In addition to general instruction, the chapters contain illustrative cases which may arise in the course of the nurse's career, a list of questions for discussion or review being added to each. The book is readable and contains helpful advice.

—*Urine Examination Made Easy*: A plan of examination with the common tests fully described by THOMAS CARRUTHERS, M.A., M.B., Ch.B. (London: J. and A. Churchill. Pp. 45. Price 1s. net), is the third edition of a little book which we have already commended to nurses, for whom it is primarily intended.

Voluntary Aid and Red Cross workers will find help from two little books by Miss ALICE SCOTT, published under the title of *Surgical Bandages and Dressings* (London: Percy Lund, Humphrys, and Co. Price 1s and 3s. 6d.). Both contain clear diagrams enabling anyone to make the various bandages required for wounded soldiers, while the larger book gives details of ward bags, slippers, shoes, and other things. Profits arising from the sale of these books will benefit the surgical branch of Queen Mary's Needlework Guild.—Another book for Red Cross workers is *Home Nursing*, by Miss E. NEWSOME (London: The Scientific Press, Limited. Pp. 159. Price 2s. 6d. net), which consists of lectures given to detachments of the British Red Cross Society. Miss Newsome, who has been a "special" school nurse for the London County Council as well as a health visitor and inspector of midwives in a county area, is an able lecturer and her *vade mecum*, which is intended for use in the home as well for Red Cross nursing classes, is thoroughly practical.—An excellent little book for class teaching is *A Short Course on First Aid in Accidents*, by Lieutenant-Colonel Sir JOHN COLLIE, M.D., and Major C. F. WIGHTMAN, F.R.C.S. Eng. (London: George Gill and Sons. Price 3d.) Though brief, the information which it contains is very practical.—A fine example of compression will be found in *A Compendium of Aids to First Aid*, by N. CORBET FLETCHER, M.B., M.R.C.S. (London: Bale, Sons, and Danielsson. Third edition. Price 6d. net), in which everything essential to first aid is simplified and tabulated. Charts and ingenious mnemonics appear on nearly every page. Colonel Cantile contributes an introduction, and we endorse his good opinion of the work.

Other more popular books call for brief notice. *Moore's Family Medicine and Hygiene for India*, Eighth edition (London: J. and A. Churchill. 1916. Pp. 672. Price 6s. net), is primarily intended for travellers and others in India who may find themselves far removed from skilled medical and surgical aid. The first edition, which obtained a prize offered by the Government of India in 1873, was written by Sir William Moore, Surgeon-General to the Government of Bombay. The present edition has been written by Major Cuthbert A. Sprawson, with the assistance of several other members of the Indian Medical Service, and incorporates recent advances in the knowledge of tropical diseases.—*A Handbook for Wives and Mothers in India*, by Dr MILDRED STALEY (Calcutta and Simla: Thacker, Spink, and Co. Pp. 344. Price 5s. net), is now in its second edition. The author's object is the prevention of disease in mothers and children during their sojourn in a tropical country, and her advice embodies the result of many years' experience in India. Particular emphasis is laid on the necessity for breast-feeding.—*To Wives and Mothers: How to Keep Yourself and Your Children Well and Strong* is a little pamphlet compiled by the Association of Infant Welfare and Maternity Centres, and published by the

National League for Physical Education and Improvement, 4, Tavistock-square, London, W.C., price 3d. It contains a series of wise counsels selected from the pamphlets issued by the association. Information concerning feeding and common ailments, such as is here contained, cannot be too widely disseminated.—*Life Saving in War Time* emanates from the Infant Welfare Propaganda Committee of the National League for Physical Education (London: Arthur Pearson, Limited. Pp. 112. Price 1s.). The pamphlet is a vigorous plea for the preservation of child-life, showing not only what has been done, what is being done, and what can be done in this direction, but also what the individual can do personally. This "campaign hand-book," as it is described, may well be in the hands of the public, for it cannot be too often reiterated that the child is the nation's most valuable asset.

New Inventions.

AN IMPROVED APPARATUS FOR DARK-GROUND ILLUMINATION IN THE EARLY DIAGNOSIS OF SYPHILIS, ETC.

At the present time the need for a really satisfactory plant for the detection of the *Spirochæta pallida* in the early diagnosis of syphilis is, I am sure, greatly felt. Now the most rapid and accurate method of detection is by means of the dark-ground apparatus, but the light which is used with this often fails to give sufficient definition. A good knowledge of optics will, no doubt, enable a comparatively feeble source of illumination to be used with satisfaction, but in routine work we do not desire to practise optics so much as to see the *S. pallida*.

With the object of obtaining a thoroughly reliable illuminant which is easily manipulated and always available without too many preliminaries, I have for some time past been working upon a design which is now completed and accessible to all, being of British manufacture and at a reasonable price.

The following are the special features of the apparatus:—
1. Extreme compactness and reliability. 2. Always ready for immediate use, and yet, if so desired, can be returned to the cupboard from consulting-room table or laboratory bench without being dissembled. 3. The hand-fed compensating arc lamp requires the minimum of adjustment. 4. Suitable for use on any existing electric supply—continuous or alternating current—coming within the range of 100–250 volts. 5. Contact is made from a wall-plug or the bayonet fitting of an ordinary electric lamp. 6. The arc projects a good steady light with ample reserve, rendering differentiation between *S. pallida*, *S. gracilis*, *S. microdentium* accurate, rapid, and comparatively easy. 7. Adapted for any type of microscope stage. 8. The price, approximately five guineas, is reasonable, and the upkeep, even for constant daily use, inexpensive. The carbons for the arc lamp are readily obtainable. 9. Each constituent part is capable of an ample range of movement, thus rendering perfect adjustment very simple.

I am indebted to Lieutenant-Colonel L. W. Harrison,

D.S.O., R.A.M.C., for having given me the benefit of his wide experience in this work, and for many practical suggestions which have helped me in the designing of this model, which is now installed in the Military Hospital, Rochester Row.

I would express my sincere thanks to the makers, Messrs. John Wrench and Sons, 50, Gray's Inn-road, for the prompt and careful manner with which they have carried out my instructions.

CLAUDE H. MILLS.

Camden-place, W.

AN AUTOMATIC DELIVERY APPARATUS FOR FLUID MEDIA.

(From the Biochemical Laboratory, Cambridge.)

DURING the course of bacteriological work undertaken for the Medical Research Committee it was necessary to tube a given amount of broth. For this purpose I devised a piece of apparatus which I now publish in the hope that it may be of general use. As will be seen from the sketch, it consists of a stiff rubber ball (D) attached by rubber tubing to a glass part, which contains two light glass valves, accurately ground in. The fluid is placed in the beaker and the rubber ball is squeezed by hand as much as possible. On allowing the ball to expand fluid is sucked up past the valve B. On repeating this operation two or three times the air is driven out and the whole of the apparatus is filled with the fluid. The ball is then compressed by means of the board and the position of the screw (C) is found which results in the delivery of the desired amount. Delivery should be made by an even pressure applied as uniformly as possible. It is important to keep the length of rubber tubing as short as possible and to use thick-walled pressure tubing. Under these conditions the volume delivered is almost independent of the rate of compression of the ball. The apparatus can be obtained from Mr. C. H. Nicholl, 1, Mackenzie-road, Cambridge.

SYDNEY W. COLE, M.A.,
University Lecturer in Medical Chemistry, Cambridge.

The Apparatus for Dark-ground Illumination.

On the left: resistance. In the middle: hood of cover laid back to expose the compensating arc lamp which travels in exact alignment along runners on the base-board. A lens set in an adjustable sleeve is seen projecting. On the right: adjustable stand for the microscope.

THE LANCET.

LONDON: SATURDAY, OCTOBER 21, 1916.

The Conference of Medical and Panel Committees.

THE Conference of representatives of Local Medical and Panel Committees of the British Medical Association will have opened its deliberations before the present number of THE LANCET appears, but a glance at the list of matters to be submitted for consideration¹ will show that definite conclusions are not likely soon to be arrived at. Among the topics included for discussion not the least important will be those arising out of Memorandum 229/I.C. recently issued by the Insurance Commissioners as a result of a conference with the medical members of the Advisory Committee and after further consultation with representatives nominated by the Insurance Acts Committee of the British Medical Association. The object of the Memorandum is to remove misapprehensions with regard to the present system of remunerating practitioners in respect of their services under the Insurance Acts, and to give them the opportunity to understand clearly the system in use. Criticisms are frequently launched in respect of remuneration as affecting medical practitioners, and complaints are made of injustice to groups or to individuals which involve the statement that the medical profession is not receiving what it was promised when National Insurance was introduced. In order to deal fully with this position the Commissioners set out their considered summary of what that promise was, and then proceed to explain the system adopted for fulfilling it. A clear understanding of the effect of his bargain is necessary for anyone who enters into a contract if he would charge the other party to it with failure in carrying out his obligations. For this reason a careful study of the Memorandum referred to is recommended to everyone who is not prepared simply to enter into the prescribed agreement and then to accept without question such remuneration as may subsequently accrue to him. The two essential facts to be borne in mind in respect of the income which any medical man may expect to derive from panel practice are to be gathered from the opening paragraphs of the Memorandum. They are, that the full annual sum to which he is entitled in respect of an insured person on his lists is only due if and when the liability to attend that person has lasted for a full year. If, for example, the patient has died or removed himself to another district after nine months, the amount due is three-quarters of the one year's fee and not the whole of it.

Secondly, the amount actually paid in respect of the patients of any medical man in any year does not take into account each removal by death or otherwise of a patient from his list or each new addition to it, with the exact date of the incident. For example, he is not paid 362/365 of the annual sum due per patient in respect of a particular patient who has gone elsewhere after living for 362 days in his district, because to obtain and to apply such nice statistics in every case would be a task beyond the powers of those administering the Acts; it would entail something in the nature of a daily census of the insured population. In the words of the Memorandum, "The data for this direct method of calculation being unavailable, it was necessary to adopt some indirect method of calculation which would yield the same result, but based upon the use of data which could in practice be obtained." "The object of the Commissioners," to quote again from their Memorandum, "in framing the methods which they have from time to time adopted for calculating the payments to be made in respect of medical benefit, has been essentially that of devising a formula of a practical kind, which taking account of data which could in practice be obtained, shall at the same time yield, both to the profession generally and to individual doctors, the sum to which they are entitled under the general bargain."

The Memorandum proceeds to deal in detail with the three main heads into which its subject naturally divides itself, these being in effect the stages through which the money from various sources must necessarily pass before reaching the pocket of the medical practitioner on the panel. The funds applicable from all sources, including the amount collected from each society in respect of its membership, have first to be gathered together by the Commissioners; secondly, to be distributed among the Insurance Committees; and, thirdly, to be distributed by the Committees to the medical men on their panels. The methods by which calculation is made of the amounts distributable to individual Committees and to individual practitioners are set out fully in the Memorandum, and would be rendered less, rather than more, clear by any abbreviated summary here. They will, no doubt, be studied with interest, and the principle followed will be better understood in future by those who, in trying to protect themselves under their contracts with Committees, have found themselves baffled by the difficulty of understanding the procedure followed. The information has been there, no doubt, for those who cared to investigate, but it has for the first time been made plain to anyone having an hour to bestow on its consideration; and it is a little singular that the explanation now given was not prepared and published sooner. The general plan followed is explained and defended in the Memorandum, and its retention may be considered certain unless a system showing a very obvious prospect of better results can be proposed. Improvement in detail so far as it can be effected is promised, and it is suggested that steps are possible for rendering more accurate lists and index registers. War has naturally had an

¹ See THE LANCET, Oct 14th, 1916, p. 688.

adverse effect upon accuracy in these, and indeed upon the whole system, and although the Commissioners decline to admit that there is serious cause of complaint, the question of the lists in munition areas is evidently receiving their attention. This is one of the matters which must be discussed and settled now, even though we are in the midst of the war, because as soon as peace is restored the cause of complaint will disappear. There is beyond question a large influx of insured persons into munition areas, and, apparently, while they are well they remain in the list of their former doctors; it is only when they are ill that they take steps to be transferred to the doctor in the munition area. The Commissioners tell us that a large proportion of munition workers leave the munition area and return home directly they fall ill, and that this has a material bearing upon the contention that the doctors of munition areas are prejudiced by the present position. We are a little sceptical as to this, and should like to know the proportion of munition workers who retain their former homes when going to a new district, and who return thither so promptly on feeling unwell that they do not have time to consult a medical man in the munition area. This is a matter to be threshed out with a view to speedy settlement, in spite of the universal desire to avoid discussion and controversy while the nation is at war. In other respects the Memorandum appears to invite criticism and suggestion while insuring the relevancy of these to the actual facts of insurance administration.

Of other matters which we understand to be before the Conference the most important would appear to be the effect of the clause to be substituted for Clause 3 of the conditions of medical service in Schedule I. of the Medical Benefit Regulations, 1913. The provision of consultant medical service in insurance practice upon an extended scale is indicated, and the Memorandum (227/LC.) issued to Insurance Committees on the subject is silent as to any increase of the ordinary practitioner's remuneration for what may prove to be a substantial increase in the work to be done. Paragraph 2 of the Memorandum refers to Clause 3 mentioned above, as requiring the panel doctor to advise the patient as to steps which he should take if in need of specialist or consultant service, but adds that this requirement is by no means exhaustive of his professional duties towards his patient, duties "which panel practitioners would themselves admit to be inherent in the professional relation of general practitioner to consultant or patient." The cases in which consultation has taken place are described as "comparatively rare," but the performance in connexion with them of professional duties, "such as furnishing particulars of the patient's clinical history or specimens for laboratory examination," is treated as if it were a matter of course, now to be made for the first time the subject of formal regulation. The medical profession has worked already for some years under an insurance system which it has done its best to render genuinely beneficial to its patients, though the spirit of medicine, as idealised

by Dr. MITCHELL BRUCE in his address on another page, cannot flourish easily in such environment. But medical men are familiar with the conditions which panel service has hitherto implied, even if they have not understood the financial side of their contract. The performance, however, of certain admittedly desirable or necessary additional work in connexion with "comparatively rare cases," does not imply willingness to undertake the same duties gratuitously under what the Memorandum defines as "an organised provision of expert services now in process of development." The development contemplated by the Commissioners may be considerable, or the employment of expert services may in practice extend beyond the original intention of those responsible for the innovation. The Memorandum appears to have in view the introduction of expert services only for the treatment of venereal disease and of disabled soldiers and sailors discharged from service, but even within the limits thus suggested the increase of duties imposed will be grave. Acquiescence, therefore, without full inquiry would be dangerous in itself, and even more so as a precedent for the future.

The Interpretation of Laboratory Reports.

QUALITATIVE analysis of the urine has been practised for a century, but the methods of HELLER and of FEHLING were simple and could be used by the practitioner without a great outlay of time. The discovery of the bacillus, and especially of the tubercle bacillus in 1882, began to induce the clinician to seek the help of the laboratory worker; with the working out of the first serum reactions by BUCHNER and BORDET, 25 years ago, these relations became complete and final. It was impossible for the practitioner to find time to analyse the vital fluids of his patients as well as their symptoms, and the type of practitioner who placed no value upon the findings of the laboratory soon began to disappear. The pendulum doubtless swung too far, and for a time, when pathological work was new and seductive, there may have been certain minds which attached too high a value to this aspect and expected the clinical findings to fit in with the laboratory reports. There were men who could not see any clinical progress in a case until they knew what the white cells of the blood had to say about it. This type has also passed away. But there may still be some to whom the laboratory report is as a thing apart. To these, to take an example, the presence of albumin in the urine in a person presenting himself for life insurance connotes non-insurability. The urine is either free from albumin and the patient insurable, or albumin is present and the patient non-insurable. The Wassermann reaction is positive, the patient, therefore, has active syphilis; it is negative, and syphilis is excluded. Such an attitude is no longer consonant with the practice of the art and science of medicine. We draw attention on p. 723 to the

existing need of a link between laboratory and workshop; and the human body is the workshop of the pathological laboratory. The scientific practitioner must train himself in the interpretation of the laboratory report precisely in the same way as he has become trained in the interpretation of symptoms.

What conclusion, then, can the practitioner rightly draw when the laboratory report is negative? Is he to conclude the absence of the disease of which a positive report would have proved the presence? A negative Wassermann is a good case in point. The paper by Dr. WILLIAM FLETCHER on the luetin reaction, which appears in another column, clearly shows that this reaction and the Wassermann reaction, while both of them specific reactions in the sense that positive results only occur in syphilis—Dr. FLETCHER is excluding from consideration certain unusual conditions alluded to below—may fail to occur in any particular case of active syphilis. In the great majority of instances Dr. FLETCHER found one or other reaction to be positive; but in a given case, even though both reactions were negative, syphilis was not absolutely excluded. In his demonstration to the London panel practitioners last week Lieutenant-Colonel HARRISON took a good deal of trouble to elucidate the various interpretations to be placed on a negative Wassermann, according to the other findings in the case. In the first place, the case might be too early and the blood taken during the incubation period; a later report would then be positive. Or the patient might be, consciously or unconsciously, under the effect of antisyphilitic treatment; a short period of discontinuance of treatment would then result in the Wassermann becoming positive. Or the case might really be cured and the spirochæte infection finally abolished; here further assurance was to be gained by the employment of a "provocative" dose—that is to say, of a small intravenous dose of 0.2 or 0.3 gm. salvarsan (or of 0.4 or 0.5 gm. of neosalvarsan), with observation of the blood 7, 14, and 21 days later. Or, finally, the negative reaction might really be evidence of absence of syphilis, but only so on repeated examination and when all the other factors had been duly considered.

The positive Wassermann also has its various possibilities to consider. In the first place there are a series of conditions apart from syphilis in which the positive reaction has been found, most of them fortunately of rare occurrence or confined to tropical areas. Of these may be mentioned relapsing fever, yaws, trypanosomiasis, malaria and scarlet fever at the height of the fever, tropical ulcer, eclampsia, and certain skin diseases such as psoriasis and urticaria pigmentosa. The last-named are naturally the most likely to give rise to diagnostic difficulty, but the reaction in them is never strongly marked, and the difficulty may be avoided by using a non-syphilitic case of the same skin disease as a control. In the second place, the positive reaction may remain throughout life in cases which have not been efficiently treated at the outset. It is by no means an unheard-of thing for a robust man in late middle life to be found to have

a positive reaction, and more than a little consideration must then be given as to whether or no treatment is indicated. These are a few of the points to be considered by the practitioner in receipt of a positive or negative laboratory report. Where the report is quantitative other considerations arise. But in any case the interpretation of the report is a matter for judgment and experience, and it will help pathologist and clinician alike that each should know the working of the other's mind. The arguments must be so prepared, or opsonised, by the one as to be capable of ready assimilation by the other.

Annotations.

"Ne quid nimis."

HIGH SPIRITS AND JUVENILE CRIME.

Memorandum No. 13 of the Health of Munition Workers Committee on the subject of juvenile employment contains a careful summary of measures for dealing with the health of young workers, particularly boys, and incidentally some concrete suggestions for checking the delinquencies which result from the present abnormal conditions of work. High wages, the lack of healthy recreation, the absence of paternal control, all tend to thriftlessness, ill-discipline, and their resulting evils. In a previous Memorandum of the Committee (No. 2, Welfare Supervision) the appointment of welfare supervisors in all factories where women and girls are employed was recommended, and the results are known to have been satisfactory. The new Memorandum No. 13 sets out the duties assigned to "Boy Visitors" in the scheme of welfare supervision which has recently been initiated at the Royal Ordnance Factories at Woolwich Arsenal. The visitors get into personal touch with the lad, keep an eye on his work, his health, and his morals, and report anything requiring attention to the proper authorities. The Memorandum emphasises the need for sympathy and personal supervision and deserves the careful attention of all who are directly or indirectly concerned with the welfare of the developing lad. That lads do respond in a remarkable way to improved environment is evidenced by the fifty-ninth Report of the Chief Inspector of Reformatory and Industrial Schools of Great Britain, which has just been issued in the form of a White Paper (Wyman and Sons, price 2½d.). In this report Mr. C. E. B. Russell gives as an item of his creed: "I believe practically every boy to be at heart good," and is prepared with facts and figures to substantiate his optimism. The following extract from his report in regard to the war record of previous scholars speaks for itself:—

Up to March 1st, 1916, 29,920 of the old boys were known to be serving, 3884 in the Navy and 26,036 in the Army, of whom 1223 have been killed in action, 150 have died of wounds, 3501 have been wounded, 172 are missing, and 434 are known to be prisoners of war. Thirty-two boys have been mentioned in despatches, 69 awarded the D.C.M., 8 have been awarded the Russian Medal of St. George, 4th Class, 3 the French Médaille Militaire, and 1 the Croix de Guerre, while 19 have obtained commissions. Four boys have been awarded the Victoria Cross.

But the same spirit of adventure which has been responsible for these awards causes anxiety at home when it takes hold of the youthful crowd in the darkened streets at night, and in certain

neighbourhoods petty larceny has been reported with unpleasant frequency. In a letter to the *Times* last week Mrs. Humphry Ward suggests that local authorities should be obliged to provide a number of convenient play-centres for school children, as she believes that with some such outlet for high spirits the major part of the present difficulties would disappear. This is a view with which we agree. Whether under parental control or not, a large number of children have nowhere else than the street to exercise their minds and bodies. Open to grave objection at any time, this limitation is a direct incitement to misdemeanour with the increasingly early hour for lowering the lights. The Education (Administrative Provisions) Act of 1907 gave permission to local authorities to provide evening play-centres, and this provision might now be made compulsory.

THE PREVENTION AND TREATMENT OF VENEREAL DISEASES IN THE METROPOLIS.

THE London County Council is not going to delay in carrying into effect the recommendations of the Royal Commission on Venereal Diseases, and facilities for treatment are to be provided at the earliest possible moment. The problem of arranging these facilities throughout Greater London is a most difficult and complicated one, but it augurs well for the success of the scheme in hand that the Lord Mayor has convened a special conference of municipal and hospital authorities and representatives of the principal religious, educational, and social organisations to meet at the Mansion House on Oct. 24th. Addresses will be given by Mr. Herbert Samuel, the Home Secretary; Mr. Walter Long, the President of the Local Government Board; Mr. A. F. Buxton, the Chairman of the London County Council; and Lord Sydenham, the President of the National Council for Combating Venereal Diseases. Others who are announced to speak, besides the Lord Mayor, are Lady Barrett, M.D., Sir Thomas Barlow, and Sir Malcolm Morris.

WEIL'S DISEASE IN FLANDERS.

Weil first described the disease which bears his name in 1886. It is characterised by jaundice, pyrexia, hæmorrhages, and was apparently infectious, occurring either as widespread epidemics or in localised groups of cases. During the Gallipoli operations there was an extensive epidemic of jaundice, and it is possible that these cases may have included an anomalous type of the same disease; a recent paper in our columns on infective jaundice by Captain N. B. Gwyn, M.D., and Captain J. J. Ower, M.D.,¹ both of the Canadian Army Medical Corps, sufficiently shows the difficulties of diagnosis that may exist. The cause of Weil's disease was not known until 1914, when Inada and Ito reported the discovery of a spirochæta in the liver of a guinea-pig which had been injected with the blood of a patient suffering from this disease. The following year they concluded that such spirochætæ were the cause of Weil's disease. Later it was found that the blood of patients recovering from this disease contained protective substances against the spirochæta. Still later Japanese workers demonstrated the same spirochætæ in six specimens of patients' blood; in two cases which died on the sixth day of illness the spirochætæ were present in large numbers in the liver. They may also be found in the urine.

The source of infection is not definitely known, but it is possible, it seems, that skin abrasions may be a path, as well as the alimentary canal. Captain Adrian Stokes and Captain John A. Ryle report in the September issue of the *Journal of the Royal Army Medical Corps* details of some 15 cases of Weil's disease in Flanders. In two of the cases it proved possible to infect guinea-pigs with the blood with typical resulting lesions and evidence of the spirochætæ. The general clinical picture is this: The patients complain of weakness and general soreness. Frequently there is pain in the eyes. Vomiting is often marked; sometimes there is epistaxis. On examination neither liver nor spleen was enlarged; the stools were of normal colour. Jaundice is marked. The pulse-rate is slow in proportion to the pyrexia. All cases showed enlarged lymphatic glands, most frequently the pectoral group of the axillary glands. All cases showed an irregular pyrexia. In six cases in which a blood examination was made, in only one were the spirochætæ easily found; in another a single spirochæta was discovered. The spirochætæ are rather straight and with curves resembling those seen in *S. refringens*. Side-to-side movements were well seen, and they were usually grouped. Cultivation was not attempted. The authors conclude that the experimental facts are sufficient to show that the cause of epidemic jaundice in Japan and in Flanders is identical.

THE MEDICAL DEFENCE UNION.

WE have received the annual report of the Medical Defence Union, which shows that the work has been increased by the war, as a great many questions have arisen out of the circumstances in which civilian practitioners have taken commissions with consequent absence from their practices. Partnership deeds have required amendment and alteration, and in some instances temporary determination; plans have had to be made for grouping of practices, and a large number of instances have occurred in which the members have derived advantage from belonging to the Union by receiving advice on such matters. The wives of many officers on active service have sought the help of the Union on numerous occasions on questions arising out of difficulties with assistants or *locum tenentes* or National Insurance Committees, and such help has always been given. Many matters affecting military law and customs have been dealt with, and in one instance a threatened court-martial was dropped owing to the intervention of the Union. This probably accounts for the fact that applications for membership have been sent from the front and candidates' forms filled up and forwarded from the trenches or casualty hospitals or field or base hospitals. Many letters have been received from those on active service who desired the Union to act for them in an emergency which had arisen in the home practice. Advice has also been sought under the Military Service Acts as to enrolment, and the secretary has been in constant touch with the executive of the Central Medical War Committee. The National Insurance Acts closely engaged the attention of the Union during the past year, and much good work was accomplished not only on behalf of its members but in the interests of the profession at large. During the year 50 cases in this connexion were placed in the hands of the solicitor to the Union, including various

¹ THE LANCET, Sept. 16th, p. 518.

appeals on the subject of surcharge. These were all conducted successfully on behalf of the members concerned. Various appeals were carried to the Commissioners against decisions of Insurance Committees concerning the conduct of the panel practitioners, and in each case undertaken a successful issue resulted. The report of the solicitor, forms interesting reading, and demonstrates the great value of belonging to such a society. The officials of the society, especially the general secretary, Dr. A. G. Bateman, and the solicitor, Mr. W. E. Hempson, together with the council, are to be congratulated on another successful year of work.

THE METROPOLITAN WATER-SUPPLY.

WITH a rainfall of 2'40 inches, or 0'18 inch above the average mean fall for June, the purity of the Metropolitan water-supply was fully maintained during that month. All the samples of water collected at the different works were, generally speaking, clear, bright, and free from suspended matter. The results of chemical examination showed that all three raw waters improved in quality during the month, as judged by the albuminoid nitrogen, permanganate, turbidity, and colour tests, with the exception of raw Thames water in regard to turbidity and colour. All the filtered waters improved in quality during the month, as judged by chemical and colour tests. When compared with the 1915 averages the raw waters showed results better than their respective averages, and the same observation was made as to the filtered waters. In regard to bacteriological results, these were consistent with the degree of purity shown by chemical results, all three raw waters containing less bacteria than their respective averages, while the filtered waters, generally speaking, yielded satisfactory results. They contained no typical *B. coli*, even when 100 cubic centimetres of the water were examined.

THE EFFECTS OF ANTITYPHOID INOCULATION IN THE ITALIAN ARMY.

A FURTHER contribution concerning the morbidity and mortality of typhoid fever in inoculated subjects may be found in some interesting observations by Captain F. Ravenna and Lieutenant A. Azzolini, of the Italian Army Medical Department, published in *Il Policlinico* (Practical Section, Sept. 17th). Comparing the course of the disease in 30 inoculated and 30 non-inoculated subjects, they found that rose-rash was present in 13 of the former and 25 of the latter, the spleen was enlarged in all cases, profuse diarrhoea occurred in 8 of the former and 12 of the latter, while hæmorrhage and intestinal perforation were apparently uninfluenced by inoculation. Broncho-pneumonia and renal complications, phlebitis, and otitis were, on the other hand, less severe and less frequent in the inoculated, and with these relapses were also more rarely met with. With regard to the height, duration, and type of the temperature, it was evident that while among the inoculated slight attacks were markedly prevalent, severe forms were common in the non-inoculated. Researches on agglutination were not conclusive owing to the fact that many of the subjects examined had undergone a mixed inoculation, and also because agglutinins are present in the circulation even nine months after the injections. With regard to the existence of antibodies capable of fixing the complement in the presence of typhoid antigen, these

observers found that out of 20 inoculated there were 18 negative reactions and sometimes incomplete hæmolysis; out of 9 cases of typhoid non-inoculated there was one positive and 8 negative, and out of 24 cases which had been inoculated there were 4 positive and 20 negative reactions. It should be noted that in all the cases giving a positive reaction agglutination of Eberth's bacillus was also obtained, and this was moreover the case in many of those instances where there was a negative complement fixation reaction, so that there was an absence of a strict parallelism between these two sets of facts. In view of the large number of patients in whom a paratyphoid infection was ascertained or suspected, a definite opinion on the diagnostic value of this test cannot be given without further experiments with paratyphoid antigens, although Dean's observations tend to show the existence of a complement deviation analogous to what takes place by agglutination.

THE REGULATION OF PROSTITUTION AND OF VENEREAL DISEASE IN SWEDEN.

IN a series of annotations we have reviewed the measures proposed by the Swedish Royal Commission on Venereal Disease, and we have shown how practically every proposal has been criticised in various quarters. After collecting and analysing these criticisms, the Swedish Board of Health has published its own views on these proposed measures, of many of which it strongly disapproves. The Board of Health points out that the Commission's investigations have shown regulation and inspection to be ineffective in controlling venereal disease; yet the Commission seems to have compromised between the logical conclusions to be drawn from its investigations and the fear of completely discarding an out-of-date system of regulation. In the opinion of the Board of Health, the Commission should have had the courage of its convictions and, following the example of the authors of the minority report, should have expressed in its proposals the conviction that regulation, in whatever form, is of doubtful value. Instead of taking this logical step, the Commission has first laid bare the faults of regulation, and has then proposed compulsory measures which constitute merely a new form of regulation, deprived of the most offensive features of the present system, but retaining all the characteristics of a genuine system of regulation. The Board of Health further considers that the positive factors in combating venereal disease, which the Commission has investigated and discussed, are not very imposing. Indeed, the Commission's many years' labour would appear from this verdict to have given a negative result. There is, however, at least one point on which the Board of Health agrees in principle with the Commission, and that is with regard to punishing persons who knowingly convey venereal disease to others. As the spread of venereal disease is almost wholly due to promiscuous cohabitation, the Board of Health considers it perfectly justifiable to make it a penal offence for anyone suffering, or suspecting that he is suffering, from venereal disease in an infectious stage to indulge in promiscuous cohabitation. Such a penal law, it is urged, would undoubtedly be a powerful check on the spread of venereal disease; it should be clearly defined and incapable of arbitrary interpretation or elasticity of administration. The maximum punishment for habitual offenders should not be less than two years' penal servitude. The

Board of Health does not anticipate serious difficulties in securing a conviction under such a law. It is illustrative of the difficulties arising out of the reform of prostitution and attempts to suppress venereal disease that the Commission has been unable to issue a unanimous report, two of its members dissenting in many respects from the majority report; the Board of Health has also been unable to point a way to reforms endorsed by all its members.

UREA IN PLANTS.

THE occurrence of the enzyme urease, which readily converts urea into ammonium carbonate, in plants, and more particularly in the soy bean, a leguminous plant named *Glycine hispida*, has naturally led to the suggestion that urea is probably a constituent of the vegetable kingdom. The suggestion is interesting inasmuch as we have for long regarded urea as exclusively an animal product. In an interesting paper read by Dr. Walter G. Smith before the Section of Medicine of the Royal Academy of Medicine in Ireland, and now published in the Transactions of the Academy, urea appears to be a fairly universal constituent of plants. It occurs, at all events, to the extent of as much as 3.5 per cent. in ripe specimens of a fungus *Lycoperdon bovista*, and it has further been found in wheat, barley, maize, peas, clover, and beans. It has also been detected in endive, some species of cucumber, brassica, spinach, carrot and potato, and so, as Dr. Smith points out, we must recognise that plants, without the help of micro-organisms, can directly form urea as a product of nitrogen metabolism. Another link is established in this way between the metabolism of plants and animals. Professor Bayliss states that there does not appear to be any urea in the soy bean itself, for extracts of the seed do not yield any ammonia. He suggests that the germinating seed may contain the enzyme arginase which would produce urea from arginin. The urea on hydrolysis by urease would then serve as a nitrogen food for the plant. The action of urease is quantitative, and is now utilised in the accurate estimation of urea in urine, its conversion into ammonium carbonate admitting of alkalimetric methods. These observations are of great interest, as they not only break down once more an old distinction, but they throw a fresh light on the metabolism of nitrogen substances, and incidentally give us a new and accurate analytical procedure.

THE NOTIFICATION OF TUBERCULOSIS IN IRELAND.

AN Irish correspondent has called attention more than once to the curious fact that while tuberculous phthisis is frequently notified in Dublin it is quite rarely notified in Belfast. The population of each city being between a quarter and half a million and the numbers of notifications being nearly constant from week to week, it was obvious that some difference of practice must be present. The discrepancy is explained by a careful study of the Tuberculosis Order for Ireland, which differs in several essential respects from the General Order for notification of tuberculosis as issued by the Local Government Board for England on Dec. 19th, 1912. In the first place, the Irish Order applies solely to the form of tuberculosis "known as tuberculosis of the lung," and only to this when the medical practitioner in attendance considers

that the sputum discharged by the person suffering is liable to communicate the disease to other persons. Furthermore, notification is only required in case the person (1) habitually sleeps or works in the same room as any other person or persons not so suffering; or (2) is employed or engaged in handling, preparing, or distributing food intended for sale to the public. The person, therefore, who lives in one room readily escapes notification, and it is open to the practitioner, if he wishes, to arrange for the nursing of most of his cases in such a way that notification is not compulsory. Differences in individual practice may accordingly readily account for the different figures obtained in Belfast and Dublin, which give no real insight into the relative prevalence of tuberculosis in the two cities. Whilst notification as practised in Ireland may serve to call the attention of the public health authority to infectious cases occurring in unhygienic surroundings, it obviously cannot be expected to give a complete picture of the prevalence of tuberculosis in any area or district. Notification in Great Britain is gradually becoming a sound basis for the initiation of preventive and curative measures; it has resulted in tracking down an immense number of "contacts" in an early and curable stage and in linking the problem of tuberculosis ever closer with the housing problem. Ireland, with its high death-rate from tuberculosis, is equally in need of these measures and is unfortunate in possessing a less effective notification order.

THE THYMUS GLAND IN "THYMUS DEATH."

"Thymus death" is one of the unsatisfying and unsatisfactory diagnoses often made in cases of sudden death in infants and children. It is said that the patients have suffered from the condition entitled the status thymicus, status lymphaticus, or, to kill two birds with one stone, the status thymico-lymphaticus. Such sudden death may occur in many ways, and if we go briefly over very familiar ground it is only for the sake of clearness. In some infants, children, and young adults "thymus death" happens early in the administration of an anæsthetic. In others the symptoms are those of a sudden and fatal attack of shortness of breath, and the death is attributed to "thymic asthma." In a third group of cases the child dies suddenly in its sleep, in an attack of bronchitis or diarrhoea, or in the course of some other disorder such as rickets that had not been thought at all dangerous. Yet other varieties of "thymus death" have been described, with the result that the diagnosis has become suspect and is not recognised at all by many physicians, surgeons, and anæsthetists. Pathologists, on the other hand, are more inclined to accept it, perhaps because the discovery of an apparently enlarged thymus and an abnormally developed system of lymphatic glands and follicles offers a convenient explanation of the occurrence of sudden deaths that are otherwise inexplicable from the point of view of morbid anatomy. Alternatively, of course, these sudden deaths may be attributed to anaphylaxis; but here, again, the diagnosis is not wholly satisfying or demonstrably correct. The literature of the subject is very large, and has recently been added to by Dr. J. A. Hammar.¹ He notes that "thymus death" has very generally been attributed to hyperplasia of the thymic medulla, or else to a low ratio of the cortex to the medulla of

¹ Svenska Läkaresällskapets Handlingar, Stockholm, 1916, xlii., 887.

the gland. Dr. Hammar has made careful microscopical and numerical examinations of the thymus glands in 16 cases of sudden death in infants and children, the material being supplied to him by various Swedish colleagues. He gives details of the observations he has made, and also sets them out statistically in curves and tables. His attention has been devoted to the relative amounts of cortex, medulla, and interstitial tissue in the thymus glands, and also to the relative and absolute numbers of the Hassall's corpuscles in them, in view of the fact that "thymus death" has recently also been attributed to excessive "epithelialisation" (or deposit of Hassall's corpuscles) in the gland. Two of his 16 cases were instances of "true thymus death," 5 were patients with acute bronchitis, 2 had broncho-pneumonia, the others had rickets or were suffocated by mucus from the gastrointestinal tract in the air-passages, and 1 had tonsillitis. In all of them death was associated with some enlargement of the thymus gland. Dr. Hammar finds that the normal newly-born child has a thymus weighing from 9 to 22 grammes, and averaging 13 grammes. Such an average thymus contains about 800,000 Hassall's concentric corpuscles, the figure varying from rather less than half a million to a million and a third. Between the ages of 1 and 5 the average weight of the thymus is 25 grammes, the figure varying between 14 and 31 grammes; between these ages the average thymus contains about 1,100,000 Hassall's corpuscles, the extremes being 600,000 and 1,900,000. Summing up, Dr. Hammar comes to the conclusion that in cases of sudden death from internal causes in infants and children the thymus gland is, as a rule, of normal size and of normal histological structure. Even in cases of "true thymus death" there is nothing to indicate any functional abnormality of importance in the thymus gland; the thymus shows no constant abnormality in the quantity or proportion of its medulla; the histological variations found fall within the normal, established by examination of the thymus glands from infants and children who have met with accidental death. Dr. Hammar is inclined to search the endocrine glands generally for the cause of death in these cases and to absolve the thymus gland from all responsibility.

THE Acting Registrar of the General Medical Council is informed that an Order of the Privy Council postponing the elections of Direct Representatives, which would otherwise be held before the end of the year, may be expected in a few days.

At the first meeting of the session of the Section of Epidemiology and State Medicine of the Royal Society of Medicine on Friday, Oct. 27th, at 8.30 P.M., a paper will be read by Captain C. G. Moor, R.A.M.C., on the Work of a Sanitary Section at a Base. Any officer of the Army or Navy Medical Services or the Indian and Colonial Services will be cordially welcomed at the meeting.

ROYAL NAVAL HOSPITAL, STONEHOUSE.—The Medical Director-General of the Navy (Surgeon-General Sir Arthur W. May) recently visited the Royal Naval Hospital, Stonehouse, where he was received by Surgeon-General W. H. Norman. He inspected the medical and surgical wards and expressed his appreciation at the provision made for the sick and wounded patients. On the following day the Medical Director-General inspected the medical establishments at Devonport and Plymouth.

THE LINK BETWEEN THE UNIVERSITY AND THE FACTORY.

INTERESTING demonstrations were given in the Universities of Leeds and Sheffield last week of the facilities which the great technological schools of the Universities are offering for carrying out scientific research. It was announced that similar demonstrations would follow shortly at Manchester, Liverpool, and Birmingham Universities. Situated as the Universities of Leeds and Sheffield are in the midst of great industrial activities, it is encouraging to learn that the work of scientific research is being prosecuted on behalf of the manufacturers, and already some important examples of new advances may be definitely traced to the coöperation of the workshop and the University laboratory.

Sheffield has been severely handicapped by the serious depletion of its students eligible for the war, but in spite of this the work done in the engineering and metallurgical departments has been of the utmost importance to the nation in the hour of its trial. The pure science side of the teaching at this University, as the Dean of the Faculty of Pure Science explained, has been rapidly developed to meet any demands made either by the city, which has, of course, a large stake in the University, or by industry now or after the war is over. Schemes have been set on foot for the training of chemical engineers for which so great a demand exists at present, and of research chemists of a type so urgently in request by many firms engaged in the large chemical industries mobilised for war purposes. A new department of technology dealing with glass has been created which it is hoped will become national in character. This has been organised with the financial support of the Advisory Committee of the Privy Council for Industrial Research, of the Ministry of Munitions, and of the glass manufacturers on the one hand, and of the Sheffield University Council on the other. Suitable buildings for research work in glass technology are in process of erection, but in the meantime the work is being carried out with very promising results in the chemistry department. Amongst other work that has been taken up is the preparation of local anaesthetics formerly made exclusively in Germany, the provision of substitutes for materials formerly imported from the continent and largely used in local industries submitted by various firms. Altogether there are sure signs that the assistance which the University of Sheffield is in a position to give to trade and industry is being increasingly appreciated by the community.

At Leeds a most interesting demonstration was given in the various departments by the respective professors. The department of organic chemistry deals mainly with those branches of science which underlie many of the most important technical processes, and provides a training for a large number of students who desire preparation for the great variety of industrial processes dependent on chemistry, such as the manufacture of dyes, explosives, and drugs, and the leather-dyeing, coal-tar, and fuel industries. This department has been actively engaged in several directions in the service of the country connected with the war. At the request of the War Committee of the Royal Society this department undertook the preparation of novocaine and eucaine, and a sufficient supply of the former has been made already. The preparation of eucaine continues. The chloramines are prepared in these laboratories as well as the hypochlorite boric acid mixture, the manufacture of which on a large scale is now in the hands of several firms of chemical manufacturers. There was on view also a collection of British-made dyes and drugs produced since the war, which are rapidly forming the basis of new industries, and this afforded a remarkable ocular proof of British energy well directed. The collaboration of science and industry was further fully illustrated in a special technical department representing what was being done for the great leather industries. The work of the bacteriological laboratory of this department since the war has been devoted to the production of culture-media required by the hospitals for the isolation and identification of disease germs. Besides all this, the technical department is busily engaged controlling the output of toluene and benzene from coal-gas and making examinations of high explosives.

The recent visit made by a representative group of enquirers and observers to the Universities of Sheffield and

Leeds proved of a most interesting and instructive character, and there can be little doubt that the value of coöperation between science and industry is being rapidly appreciated. The old rule-of-thumb policy and practice of our manufacturers must eventually disappear, much to the advantage of the nation's prestige in the industrial field. Both at Sheffield and Leeds the visitors were received by the Vice-Chancellors respectively of the Universities, who rendered a scholarly account of what these centres of education were doing to raise the status of technology. In each case the party of visitors proceeded from the University to the great factories and works—steel, leather, and textiles—where they could see for themselves how the fruits of scientific research of the University were being utilised with the most valuable results. A magnificently important movement has been set on foot the consummation of which will enhance very considerably the welfare and prosperity of the nation.

For the most part the visitors represented a circle of scientific, technical, and trade journals forming a section of the Institute of Journalists, which body may be congratulated on organising a movement for informing the public of the practical progress that has been and is being made.

BACILLARY DYSENTERY AND B. ENTERITIDIS (GAERTNER) INFECTIONS.

THE following Memorandum records the extension of the supply of standards from the Department of Pathology at Oxford and is issued to meet the convenience of bacteriologists at military hospitals and assist the coördination of results obtained by different observers at different times and places. The Medical Research Committee have made arrangements for the preparation and supply of sterilised Standard Agglutinable Cultures and Standard Agglutinating Sera, for the diagnosis of certain intestinal infections by means of macroscopic agglutination tests.

The preparation of standard cultures and sera carried out in the Department of Pathology, Oxford, under the direction of Professor G. Dreyer, has now been extended to include *B. dysenteriae* (Shiga, Flexner, and Y.) and *B. enteritidis* (Gaertner), in addition to *B. typhosus*, *B. paratyphosus* A, and *paratyphosus* B. The standard cultures and sera will be supplied by the Medical Research Committee free of charge to pathologists working in connexion with military hospitals. Applications for the standard cultures or sera should be addressed to the Standards Laboratory, Department of Pathology, University of Oxford (telegraphic address, "Pathology, Oxford," telephone, Oxford 467).

To facilitate the performance of agglutination tests under service conditions or otherwise, a special outfit has been prepared. This consists of a special stand, dilution tubes, agglutination tubes, and two dropping pipettes, which can be obtained free of charge by pathologists working for military hospitals upon application to the Medical Research Committee, 15, Buckingham-street, Strand, W.C., or may be purchased from Messrs. Baird and Tatlock, 14, Cross-street, Hatton-garden, E.C., or from Messrs. R. B. Turner and Co., 9, Eagle-street, Southampton-row, W.C., price 4s. 6d. each set. Full directions for use will be sent out with each set of apparatus and with all standard cultures. And under service conditions the standard agglutinable cultures will be supplied in quantities sufficient for all ordinary routine work. When application is made for them the probable weekly number of agglutination tests to be made should be stated.

The standard agglutinating sera for *B. dysenteriae* (Shiga, Flexner, and Y.) and *B. enteritidis* (Gaertner) will be provided either for the identification of these several forms or for the use in the standardisation of killed agglutinable cultures.

The use of the standard agglutinable cultures, with the set of apparatus as provided, is believed to offer the following advantages:—1. The procedure is simple and rapid. 2. The materials are always ready, and no cultures have to be incubated and prepared. 3. The culture is killed and all risk of infection is absent. 4. The reaction can be carried out at any temperature between 35°C. and 56°C., or even at room temperature if necessary. 5. No microscope is needed. 6. Owing to the precise quantitative determination which it allows, the method enables the worker to follow the course of the agglutination curves obtained by successive examinations, and thus facilitates the diagnosis of active disease. 7. The results obtained possess standard uniformity even in relatively unpractised hands, and are strictly comparable from case to case and from day to day, wherever the tests are

performed. The expression of the results in standard agglutinin units allows the comparison of extensive series of observations in different laboratories and at various times for statistical or other purposes.

The Medical Research Committee point out that the standardised cultures and sera already provided for *B. typhosus*, *B. paratyphosus* A, and *B. paratyphosus* B have been in use at the chief military laboratories engaged in work upon enteric fever cases and carriers with the Expeditionary Force and at home for over a year. It is hoped that in the interests of uniformity of results and the unification of records the new standards now made easily available may be generally adopted.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal Academy of Medicine in Ireland.

THE annual meeting of the Royal Academy of Medicine was held on Oct. 13th. The General Council reported that the number of Fellows was 144, of members 17, and of student associates 8, compared with 149 Fellows, 16 members, and 5 student associates in the previous session. Several meetings had been abandoned at the end of last session owing to the rebellion and the subsequent state of martial law. The annual elections resulted in the election or re-election of the following officers: President: Dr. R. D. Purefoy; general secretary: Dr. J. A. Scott; secretary for foreign correspondence: Sir John W. Moore; and of the following as presidents of sections: Medicine, Dr. H. O. Drury; Surgery, Mr. W. Taylor; Obstetrics, Dr. G. FitzGibbon; Pathology, Dr. E. J. McWeeney; Anatomy and Physiology, Professor E. J. Evatt; State Medicine, Dr. W. A. Winter.

Scene at an Asylum.

At the last meeting of the committee of management of the Ballinasloe District Asylum Mr. John Mills, who had been assistant medical officer for 23 years, was elected resident medical superintendent. An extraordinary scene ensued. The news quickly reached the inmates of the institution and loud cheers could be heard from all parts of the building. Several of the patients came from the dining-hall and demanded the doctor's presence. On emerging from the board room he was seized by the patients, who put him on their shoulders, and amidst great cheering he was carried through the corridors.

Proposed Midwifery Legislation for Ireland.

The Local Government Board for Ireland is engaged in drafting a Midwives Bill for Ireland on similar lines to those of the Scottish Bill, and has recently had a conference with a medical committee appointed on the initiative of the Irish Medical Association. It is understood that the two bodies are in substantial agreement. The Local Government Board accepted a suggestion of the committee that the period of practice entitling an existing midwife to register should be three years instead of one year as in the Scottish Act. The Board has promised to consult the committee again before the draft Bill leaves its hands.

Royal Humane Society: Awards to Irish Medical Men.

The last list of awards made by the committee of the Royal Humane Society for gallant actions in saving, or attempting to save, life contains the names of two Irish medical men. Mr. Cornelius Hickey, of Kilkee, is awarded a bronze medal for saving a man and woman from drowning at Kilkee. The woman first got into difficulty, and the man, going to her help, was also in danger. Mr. Hickey, though fully clothed, swam to their assistance, and rescued both. Mr. James Roberts, of Limerick, was awarded a testimonial for his courageous rescue of a man from a rough sea at Kilkee.

A New Type of Epidemic in Belfast.

During the past month many varieties of a disease presenting some unique clinical features have been met with in Belfast. Some of the cases are ushered in with high temperature and diarrhoea, others have no temperature and very slight relaxation of the bowels, but all have certain features in common—loss of appetite, general malaise, and abdominal pain. The last symptom is the most characteristic; it occurs mainly over the lower abdomen and is attended with

tenderness on pressure, sometimes markedly on the right side, and the first idea that is suggested to the medical attendant is that an attack of appendicitis is threatening. The pain, however, soon moves to other parts of the abdomen, especially along the course of the large bowel, and the subsequent history of the patients seems to indicate that the colon has been the seat of some bacillary affection. In other cases during the convalescence pains of a "myalgic" nature occur in the back and in the limbs. Some medical men who have been at the front think the cases bear a certain resemblance to a type of the "trench fever," some of which, it appears, have at first been mistaken for appendicitis. Fortunately, in Belfast the great majority of those attacked, whether the onset is sudden and severe or more gradual and mild, soon recover. It has been common in former years to have cases of ordinary autumnal diarrhoea at this season, but the present epidemic is of an entirely different nature, its most characteristic feature being the abdominal pain and acute tenderness on pressure.

Doctors and the Military Age.

On Oct. 14th Mr. J. J. Todd, medical officer of Omagh Dispensary District, asked for temporary leave of absence and tabled a certificate from a famous cardiac specialist to the effect that the state of his heart made it necessary that he should have a period of rest. The Board, after a discussion, granted sick leave to Mr. Todd, and appointed Dr. D. F. Murnaghan as temporary substitute, but he is of military age and so ineligible.

Oct. 17th.

THE SERVICES.

ROYAL NAVAL MEDICAL SERVICE.

Temporary Surgeons: T. W. Robbins and J. A. M. Alcock.

ARMY MEDICAL SERVICE.

Temporary Colonel Henry A. Thomson, C.M.G. (Captain, R.A.M.C., T.F.), relinquishes his temporary commission.

ROYAL ARMY MEDICAL CORPS.

Major A. E. Snell, C.A.M.C., to be Assistant Director of Medical Services, and to be temporary Colonel whilst so employed.

Major E. E. E. Powell, from Supernumerary List, to be Lieutenant-Colonel, vice Lieutenant-Colonel J. S. Green, placed on retired pay.

Major (temporary Lieutenant-Colonel) F. S. Irvine, D.S.O., to be Lieutenant-Colonel.

The undermentioned are granted temporary rank whilst employed at the Manor (County of London) War Hospital:—As Lieutenant-Colonel: W. I. Donaldson. As Major: S. C. Elgee.

Temporary Captain F. G. W. Deane to be temporary Major whilst in charge of the Springburn and Woodside War Hospital.

To be temporary Captains: S. K. Adams, T. Redmayne, H. Fraser, Lieut. W. A. Costane, C.A.M.C., and Hon. Major N. C. Wallace, C.A.M.C.

Temporary Captains relinquishing their commissions: H. J. Hutchens, A. G. Mossop, G. M. W. Hodges, A. D. Haydon, A. M. Fisher (on account of ill-health), T. G. Moorhead, W. Templeman (on account of ill-health), and P. Northcote.

Temporary Lieutenants to be temporary Captains: J. Pirie, F. McE. Sinclair, W. J. Hicks, J. W. Riddoch, A. L. Badcock, D. A. Evans, J. C. Hindley, J. S. Gilchrist, J. D. Watson, J. M. Macfie, W. G. D. McCall, J. V. Grant, W. Cunningham, J. A. Leiper, P. C. Davie, J. C. Knox, F. G. Cross, T. H. Sarsfield, N. B. Loughton, F. R. Sturridge, J. P. Lusk, H. R. W. Husbands, J. T. MacKenzie, T. J. Gilmore, M. S. Bryce, J. Campbell, C. C. B. Gilmour, D. M. R. Crighton, R. F. Linton, A. L. Anderson, F. J. Hathaway, G. B. McTavish, G. Walker, A. W. P. Todd, A. H. Coleman, T. Pretsell, J. Beatty, G. F. Gill, T. J. Buckley, J. C. Boyd, J. McKie, E. J. Storer, L. C. Martin, M. Sommerville, J. S. Findlay, P. C. Litchfield, J. Watson, R. A. Fuller, J. Philp, E. G. B. Calvert, P. Sturrock, J. E. Taylor, J. B. Thackeray, A. G. Winter, H. H. Mathias, L. M. Ingle, J. A. Liley, J. L. Graham-Jones, H. P. Newsholme, J. K. Morton, V. G. Williams, G. Marshall, R. L. Norman, F. L. Pelly, H. J. Bell, T. F. Shackleton, C. G. A. Chislett, G. F. Oldershaw, W. Shanks, G. O. Connell, F. W. Joynes, F. J. Kirkness, A. G. Mowat, A. A. Miller, H. P. Crampton, R. W. Shegog, J. F. Hoare, A. C. T. Woodward, J. L.

Hendry, G. W. Charsley, W. Fairclough, W. B. Thompson, T. B. Riddall, J. R. Dobbin, J. MacKinnon, C. C. Irvine, L. M. Rowlette, D.S.O., C. S. Van R. Harwood, J. D. O'Connor, A. G. Naismith, E. G. Fenton, R. L. Ley, O. A. J. N. Muriset, T. Kelly, S. Bryson, H. J. Flanagan, W. W. Uttley, G. H. Powell, M. Davidson, J. F. Bullar, G. M. Grant, C. S. Pantin, W. H. Best, J. M. Anderson, W. Warburton, A. Stodart-Walker, C. M. Stubbs, G. F. Fawn, R. Park, W. N. Gilmour, A. E. Hockett, F. G. Martin, W. Core, J. H. C. Gatchell, E. T. Jones, F. B. Manser, J. E. McCartney, W. E. A. Buchanan, R. P. Kennedy, R. J. Aherne, R. N. Farrer, W. Herbertson, E. W. Craig, A. H. Murch, E. C. Mackay, A. S. Hendrie, A. G. Hamilton, P. Gettleson, J. Joule, R. J. Cane, W. Stanwell, D. J. McAfee, G. Coates, E. G. Evans, F. R. Snell, R. Felton, E. Brown, V. M. Fisher, W. Millerick, D. F. Macdonald, R. A. Fawcus, S. R. Lane, G. L. Parsons, F. Dillon, O. A. Beaumont, W. A. Clayton, A. Macintyre, W. G. Macdonald, G. W. Riddell, F. N. Brown, N. F. Lock, H. Young, L. R. Thomson, B. A. Cheadle, C. E. Meryon, G. G. Bruce, J. G. Castellain, A. C. West, J. G. S. Mennie, M. B. Lindsey, F. C. Plummer, A. B. MacLean, B. C. Scott, R. B. John, D. Dunlop, E. V. Frederick, W. J. M. Marcy, J. W. Littlejohn, W. R. W. Asplen, A. Brown, D. Fisher, W. T. Finlayson (from Unattached List), R. C. MacQueen, A. H. Style, and M. G. Dobblyn.

Temporary Hon. Lieut. W. E. Coe to be Temp. Hon. Captain while employed with the St. John Ambulance Brigade Hospital.

Temporary Lieutenants relinquishing their commissions: J. Macnamara, A. S. Robinson, M. M. Adams, J. L. Wilson, A. Todrick, J. S. Doyle, W. A. Costain, E. R. Holborow, A. W. Cassie, J. Bain, H. G. Ward, H. A. Bodkin, R. V. Howell, H. J. Foote, J. Wyper, N. Bradley, C. D. Halcomb, R. E. B. Yelf, A. Gardner, F. MacRae, R. Fox, J. MacM. Watson, R. A. Wilson, H. I. G. Rutherford, E. Doherty, G. E. Lloyd, M. E. H. Wale, N. Leonard, J. B. J. L. Dalby, J. H. Potter, W. A. Stuart, A. R. Munroe, R. O. Whyte, J. A. Proudfoot, C. A. Everest, J. O. Baker, A. C. Johnston (on account of ill-health), W. P. Taylor, and W. A. Twigg.

To be temporary Lieutenants: Lieut. S. G. Kean, C.A.M.C., D. E. Scott, C. M. Keillor, T. E. R. Branch, R. W. S. Christmas, G. L. Crimp, W. J. H. Hepworth, F. H. Wolfe, J. Longworth, R. S. Kennedy, J. C. Nixon, J. F. Elliott, R. W. S. Walker, J. L. Gregory, Temp. Hon. Lieut. W. Farquharson, Temp. Hon. Lieut. A. R. Fuller, L. H. Taylor, P. C. E. d'Erf Wheeler, J. W. Turner, W. Arnott, J. F. Carroll, A. C. B. Biggs, F. Rogerson, F. W. Waterworth, A. L. Home, G. Fleming, F. W. M. Palmer, Lieut. W. S. Wallace, C.A.M.C., Lieut. R. H. Thomas, C.A.M.C., Lieut. G. H. Ensing, C.A.M.C., C. H. L. Rixon, J. G. Fraser, L. Bathurst, E. A. W. English, C. Murphy, J. McC. Gibson, A. Binning, A. T. Cooper, A. I. Miller, E. G. D. Menzies, J. Robertson, R. Edwards, G. J. Meldon, F. S. Poole, J. J. Hart, G. H. Randolph, E. H. Drake, P. C. C. Smith, W. S. Darby, C. E. A. Wilson, R. J. B. Leney, A. B. Rendel, A. Reid, C. W. Emlin, A. Boothroyd, C. A. Birts, R. J. Harley-Mason, J. B. Cook, H. H. Weir, W. C. Sharpe, A. J. Kearney, J. R. Thompson, T. W. Pattinson, W. Lessey, H. Blyth, J. B. Wall, Lieut. B. O. Kinney, C.A.M.C., Lieut. G. L. Gall, C.A.M.C., Lieut. C. M. Anderson, C.A.M.C., Lieut. F. G. Pedley, C.A.M.C., Lieut. W. C. Brown, C.A.M.C., Lieut. M. A. Harrington, C.A.M.C., Lieut. J. W. MacKie, C.A.M.C., Lieut. F. J. Colling, C.A.M.C., R. B. Martin, A. J. McNair, A. B. Lindsay, B. B. Sapwell, jun., W. E. Glover, K. W. D. MacRae, H. T. Evans, W. Brennan, W. W. Dempster, G. Saporiti, J. Leach, Temp. Hon. Lieut. R. Curle, J. Robertson, W. H. Whitehouse, C. E. O'Keffe, J. C. Murray, and E. A. C. Beard.

J. McMurray to be temporary Lieutenant whilst employed with the Cape Labour Corps.

SPECIAL RESERVE OF OFFICERS.

Supplementary to Regular Units or Corps: Major J. H. P. Graham to be temporary Lieutenant-Colonel whilst in command of a General Hospital.

Captains to be Temporary Majors whilst in command of Field Ambulances: W. Darling, J. Adams, K. D. Murchison, D. C. Barron, M. R. Taylor, and M. W. Paterson.

Captains (Temporary Majors) relinquish their temporary rank on re-posting: W. Darling and M. W. Paterson.

Lieutenants to be Captains: K. P. Brown, H. D. Wright, W. H. Ferguson, J. A. Crawford, and G. Morris.

Lieutenant on probation C. A. W. Ramsay is confirmed in his rank.

To be Lieutenants: D. R. Hennessy, S. J. V. Furlong, J. Y. Maclean, D. Roger, M. McGillivray (from St. Andrews University Contingent Officers Training Corps), T. D. Renwick, and L. P. Johns (from University of London Officers Training Corps).

TERRITORIAL FORCE.

Highland Field Ambulances: Lieutenants seconded for duty with a Stationary Hospital: B. L. Davis and A. G.

Reid. Officers seconded for duty with a Stationary Hospital: Major (temporary Lieutenant-Colonel) A. E. Kidd, Captain A. B. Jamieson, Captain G. McConnell, Captain A. R. Moodie, Captain C. G. Skinner, and Lieutenant J. Steele.

Wessex Field Ambulance: Captain W. A. Valentine is seconded for duty with a Stationary Hospital.

London General Hospital: Captain P. H. Mitchiner is seconded for duty with a Stationary Hospital.

Wessex Casualty Clearing Station: Officers seconded for duty with a Stationary Hospital: Captain (temporary Major) A. C. Alport, Captain J. Fenton, Captain C. A. Raison, and Lieutenant A. C. Smith.

Welsh Border Mounted Brigade Field Ambulance: Lieutenant J. Derham-Reid to be Captain.

Northumbrian Field Ambulance: H. Evers to be Lieutenant.

London Sanitary Company: To be Captains: Lieutenant J. A. Andrews and Lieutenant A. E. Jury.

Attached to Units other than Medical Units.—R. Elliot Pitts to be Lieutenant.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS

IN the 96 English and Welsh towns with populations exceeding 50,000 persons at the last Census 7144 births and 4161 deaths were registered during the week ended Saturday, Oct. 7th. The annual rate of mortality in these towns, which had steadily increased from 10.5 to 13.5 per 1000 in the seven preceding weeks, fell in the week under notice to 12.5 per 1000 of their aggregate civil population, estimated at 17,312,295 persons for the year 1915. During the 13 weeks of last quarter the mean annual death-rate averaged 11.4, against 11.1 per 1000 in London. Among the several towns the death-rate during the week ranged from 5.4 in Gloucester, 6.2 in Barnsley, 6.6 in Bath, 6.9 in Barrow-in-Furness, and 7.0 in Ipswich, to 17.2 in Wakefield, 17.5 in West Bromwich and in Liverpool, 18.6 in Rotherham, 18.8 in Carlisle, and 19.7 in Tynemouth.

The 4161 deaths from all causes were 319 fewer than the number in the previous week, and included 412 which were referred to the principal epidemic diseases, against numbers declining from 594 to 488 in the three preceding weeks. Of these 412 deaths, 294 resulted from infantile diarrhoeal diseases, 52 from diphtheria, 25 from measles, 15 from whooping-cough, and 13 each from enteric fever and scarlet fever, but not one from small-pox. The annual death-rate from these diseases was equal to 1.2, against 1.5 per 1000 in the previous week. The deaths of infants (under 2 years) from diarrhoea and enteritis, which had been 477, 448, and 384 in the three preceding weeks, further fell to 294, and included 62 in London, 34 in Liverpool, 16 in Birmingham, 12 each in West Ham and Sheffield, and 10 each in Hull and Manchester. The deaths attributed to diphtheria, which had been 35, 39, and 40 in the three preceding weeks, further rose to 52, of which 12 occurred in London, 6 in Liverpool, and 3 each in West Ham and Sheffield. The fatal cases of measles, which had been 29, 21, and 23 in the three preceding weeks, rose to 25, and included 10 in London, 4 in West Ham, and 3 in Sheffield. The deaths attributed to whooping-cough, which had been 33, 28, and 20 in the three preceding weeks, further fell to 15, of which 3 were registered in Manchester and 2 in London. The deaths referred to enteric fever, which had been 9, 4, and 11 in the three preceding weeks, rose to 13, and included 3 in London. The fatal cases of scarlet fever, which had been 11, 8, and 10 in the three preceding weeks, rose to 13, of which 3 occurred in London and 2 in Plymouth.

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had been 980, 1012, and 1020 at the end of the three preceding weeks, further rose to 1037 on Saturday, Oct. 7th; 159 new cases were admitted during the week, against 130, 158, and 151 in the three preceding weeks. These hospitals also contained on Saturday, Oct. 7th, 1357 cases of diphtheria, 73 of measles, 50 of whooping-cough, and 38 of enteric fever, but not one of small-pox. The 988 deaths from all causes in London were 127 below the number in the previous week, and corresponded to an annual death-rate of 12.0 per 1000. The deaths referred to diseases of the respiratory system, which had increased from 66 to 130 in the five preceding weeks, further rose to 136 in the week under notice.

Of the 4161 deaths from all causes in the 96 towns, 148 resulted from different forms of violence, 309 were the subject of coroners' inquests, and 1241 occurred in public institutions. The causes of 42, or 1.0 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Sheffield, Leeds, Bristol, West

Ham, Nottingham, Leicester, and in 67 other smaller towns. Of the 42 uncertified causes, 7 were registered in Birmingham, 5 in Liverpool, 4 in London, 3 in Manchester, and 2 each in Bootle, Blackburn, Rotherham, and Gateshead.

In the 96 English and Welsh towns with populations exceeding 50,000 persons at the last Census 7826 births and 4071 deaths were registered during the week ended Saturday, Oct. 14th. The annual rate of mortality in these towns, which had been 12.8, 13.5, and 12.5 per 1000 in the three preceding weeks, further fell in the week under notice to 12.3 per 1000 of their aggregate civil population. Among the several towns the death-rate ranged from 4.3 in Oxford, 4.4 in Eastbourne, 6.5 in Newport (Mon.), 6.8 in Enfield, and 6.9 in Edmonton, to 17.3 in Gloucester, 18.7 in Middlesbrough, 19.6 in Rochdale, 20.7 in Barnsley, and 21.8 in Bootle.

The 4071 deaths from all causes were 90 fewer than the number in the previous week, and included 367 which were referred to the principal epidemic diseases, against numbers declining from 594 to 412 in the four preceding weeks. Of these 367 deaths, 259 resulted from infantile diarrhoeal diseases, 45 from diphtheria, 23 from whooping-cough, 21 from measles, 10 from enteric fever, and 9 from scarlet fever, but not one from small-pox. The death-rate from these diseases was equal to 1.1, or 0.1 per 1000 less than that recorded in the previous week. The deaths of infants (under 2 years) from diarrhoea and enteritis, which had declined from 477 to 294 in the four preceding weeks, further fell to 259, and included 72 in London, 24 in Liverpool, 12 in Sheffield, 11 in Birmingham, and 7 in Bristol. The deaths attributed to diphtheria, which had increased from 35 to 52 in the four preceding weeks, fell to 45, of which 9 were registered in London, 4 in Birmingham, and 3 each in Liverpool and Carlisle. The fatal cases of whooping-cough, which had been 28, 20, and 15 in the three preceding weeks, rose to 23, and included 4 in Great Yarmouth and 3 each in Bootle and Manchester. The deaths referred to measles, which had been 21, 23, and 25 in the three preceding weeks, fell to 21; 6 deaths occurred in London, 3 in West Ham, and 2 each in Wolverhampton, Birmingham, and Manchester. The deaths attributed to enteric fever, which had been 4, 11, and 13 in the three preceding weeks, fell to 10, and included 4 in London and 2 in Manchester. The fatal cases of scarlet fever, which had been 8, 10, and 13 in the three preceding weeks, fell to 9, of which 3 occurred in London.

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had increased from 980 to 1037 in the four preceding weeks, further rose to 1074 on Saturday last; 167 new cases were admitted during the week, against 158, 151, and 159 in the three preceding weeks. The cases of diphtheria, which had been 1292, 1294, and 1357 at the end of the three preceding weeks, further rose to 1410; 194 new cases were admitted during the week, against 186, 193, and 228 in the three preceding weeks. These hospitals also contained on Saturday last 70 cases of measles, 47 of whooping-cough, and 43 of enteric fever, but not one of small-pox. The 966 deaths from all causes in London were 22 below the number in the previous week, and corresponded to an annual rate of 11.7 per 1000. The deaths referred to diseases of the respiratory system, which had increased from 66 to 136 in the six preceding weeks, fell to 132 in the week under notice.

Of the 4071 deaths from all causes in the 96 towns, 187 resulted from violence, 342 were the subject of coroners' inquests, and 1239 occurred in public institutions. The causes of 46, or 1.1 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Sheffield, Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, and in 70 other smaller towns. Of the 46 uncertified causes, 11 were registered in Liverpool, 9 in Birmingham, 4 in Gateshead, and 2 each in Leicester, Manchester, Hull, Sunderland, and South Shields.

HEALTH OF SCOTCH TOWNS.

IN the 16 largest Scotch towns with an aggregate population estimated at 2,372,000 persons at the middle of this year 1035 births and 685 deaths were registered during the week ended Saturday, Oct. 7th. The annual rate of mortality in these towns, which had been 13.0, 14.5, and 13.6 per 1000 in the three preceding weeks, rose to 15.1 per 1000 in the week under notice. During the 13 weeks of last quarter the mean annual death-rate in these towns averaged 12.6, against a corresponding rate of 11.4 per 1000 in the large English towns. Among the several towns the death-rate in the week under notice ranged from 6.7 in Hamilton, 7.8 in Ayr, and 10.2 in Leith and in Kirkcaldy, to 17.7 in Aberdeen, 18.8 in Greenock, and 21.0 in Kilmarnock.

The 685 deaths from all causes were 67 in excess of the number in the previous week, and included 92 which were referred to the principal epidemic diseases, against 104 and 75 in the two preceding weeks. Of these 92 deaths, 66

resulted from infantile diarrhoeal diseases, 8 from measles, 7 from scarlet fever, 5 from diphtheria, 4 from whooping-cough, and 2 from enteric fever, but not one from small-pox. The annual death-rate from these diseases was equal to 2.0, against 1.2 per 1000 in the large English towns. The deaths of infants (under 2 years) from diarrhoea and enteritis, which had been 50, 83, and 50 in the three preceding weeks, rose to 66, and included 44 in Glasgow, 5 each in Dundee and Paisley, 4 in Aberdeen, and 3 in Edinburgh. The deaths attributed to measles, which had been 4, 4, and 5 in the three preceding weeks, rose to 8, and comprised 3 in Glasgow, 2 each in Edinburgh and Dundee, and 1 in Leith. The fatal cases of scarlet fever, which had been 3, 3, and 6 in the three preceding weeks, numbered 7, and included 2 each in Glasgow, Edinburgh, and Paisley, and 1 in Kilmarnock. The deaths referred to diphtheria, which had been 6, 5, and 9 in the three preceding weeks, fell to 5, and were all registered in Glasgow. The 4 deaths from whooping-cough were slightly below the weekly average of last quarter, and included 2 in Glasgow. The fatal cases of enteric fever were recorded in Glasgow and Edinburgh.

The deaths referred to diseases of the respiratory system, which had increased from 45 to 72 in the four preceding weeks, further rose to 94 in the week under notice, but were 22 below the number registered in the corresponding week of last year. The deaths from violence numbered 36, against 41 and 25 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the registration area of Dublin 204 births and 142 deaths were registered during the week ended Saturday, Oct. 7th. The annual rate of mortality, which had been 17.3, 15.6, and 18.3 per 1000 in the three preceding weeks, rose to 18.7 in the week under notice, against 12.0 and 15.7 per 1000 in London and Glasgow respectively.

The 142 deaths from all causes included 35 of infants under 1 year and 33 of persons aged 65 years and upwards. Fourteen deaths (of infants under 2 years) were referred to diarrhoeal diseases, and 3 each to enteric fever, whooping-cough, and diphtheria. The causes of 3 deaths were the subject of coroners' inquests, and those of 3 others were uncertified, while 50, or 35 per cent., of the total deaths occurred in public institutions.

During the same period 153 births and 105 deaths were registered in the city of Belfast. The deaths corresponded to an annual rate of 14.0, or 0.6 per 1000 higher than that in the previous week, and included 19 of infants under 1 year and 20 of persons aged 65 years and upwards. Two deaths (of infants under 2 years) were referred to diarrhoeal diseases and 1 each to enteric fever and measles. The causes of 4 deaths were the subject of coroners' inquests, and 26 of the total deaths occurred in public institutions.

Obituary.

W. A. MEREDITH, M.B., C.M. EDIN., F.R.C.S. ENG.,
CONSULTING SURGEON TO THE SAMARITAN FREE HOSPITAL FOR WOMEN.

Mr. William Appleton Meredith, whose death we briefly recorded last week, was born in New York in 1848. He was brought up at Boulogne, and thus acquired a thorough knowledge of the French language. His medical education began and ended at University College Hospital, where he held the posts of house surgeon to Sir John Erichsen and resident medical officer. But there was an interval during which he went to Edinburgh in order to obtain a medical degree. There he saw much of Lister's practice and made the acquaintance of Knowsley Thornton. Soon afterwards, at Lister's suggestion, Thornton came to London to assist Sir Spencer Wells in his enormous private practice, then by far the largest in London; and when, after some years, Thornton left Spencer Wells, Meredith took his place. Before this his knowledge of French had stood him in good stead whilst acting as the medical attendant to the well-known Belgian Minister, Baron Van der Weyer, in which capacity he formed a large social acquaintance. In the course of time Thornton became the most prominent London ovariologist, and Meredith, when the arrangement with Spencer Wells came to an end, worked with Thornton for some years.

Thornton's early retirement left the field open, and Meredith, who had profited by the great experience of Spencer Wells and Thornton and was thoroughly versed in Lister's antiseptic methods, was not slow to grasp the opportunity offered. He was already known as an extremely

careful though rather slow operator, who devoted the most meticulous attention to every detail of treatment. Successful ovariologists were few and far between. He therefore soon acquired a large and lucrative practice, and, as he was surgeon to the Samaritan Hospital, he had opportunities of showing in public that he belonged to the camp of antiseptic ovariologists, who at that time were in constant conflict with those who decried Lister's methods. But he did not add much to the literature of the subject.

In the meantime, Mr. and Mrs. Meredith had developed an interest in many things outside the medical profession. Their house in London became filled with a well-selected collection of rare old furniture and plate, and their holidays were spent at a country house in Hertfordshire. It was no surprise to Meredith's friends when they heard that he, before most men think of retiring, was about to give up London and make his home in Norfolk, where, ever since, he spent his time in country pursuits.

Meredith was not a breaker of new ground like Spencer Wells and Thornton; but he was an extremely successful surgeon. He was a rigid follower of Lister's methods, and did not hesitate to employ antiseptics in the course of operations on the peritoneal cavity.

JAMES BERESFORD RYLEY, M.D. BRUX.,
M.R.C.S. ENG., L.R.C.P. EDIN.

Dr. James Beresford Ryley, whose death occurred at his bungalow residence at Shoreham-by-Sea on Oct. 13th, had resided at Shoreham about six years, making periodical journeys to London in pursuance of professional duties. At Shoreham he was a well-known figure owing to his active participation in local affairs, and the news of his rather sudden end came as a surprise to many friends and patients. Born in India 77 years ago, he was a son of Major Beresford Ryley, of the Bengal Artillery. He came to this country at an early age and was educated in Ireland. Taking medicine as his profession, he studied at the Royal College of Surgeons in Ireland and the University of Edinburgh. He took the L.S.A. diploma in 1864, became M.R.C.S. Eng. in 1866, L.R.C.P. Edin. in 1868, proceeding to the M.D. degree in Brussels in 1879. He was for a time president of the Brussels Medical Graduates' Association. One of his earliest appointments was as a surgeon on H.M.S. *Warspite*, and, settling down in London, he held a large number of appointments. He made several contributions to THE LANCET.

EMILE LAGRANGE, M.D. LOUVAIN.

Dr. Emile Lagrange, the well-known Ypres physician, died at Leeds, where, as a refugee, he has been since the beginning of the war the honoured guest of the St. Chad's Belgian Refugees' Committee. Descended from an old Flemish family, he was born at Ypres in 1824, and after taking his degree at the University of Louvain he entered upon practice in his native city and for 50 years was attached to the hospital there. For his services to the State on the occasion of an outbreak of cholera he received the decoration of the Croix Civique and later that of the Order of Leopold. Dr. Lagrange, whose faculties remained active till the day of his death, had watched the development of modern Belgium with the anxiety of a true patriot, and it is pathetic that his death should have occurred in a foreign, albeit friendly, country at a time when his own country is passing through her hour of trial. His recollections included the signing of the treaty of 1839 (the famous "scrap of paper") and the visit of Queen Victoria with the Prince Consort to her uncle Leopold I. in Belgium.

DEATH OF MR. CHAUNCEY PUZEY, F.R.C.S.—Mr. Chauncey Puzey, consulting surgeon to the David Lewis Northern Hospital, and one of the best-known surgeons in Liverpool, died at his residence, Princes-avenue, West Kirby, on Oct. 10th. Receiving his medical education at Guy's Hospital, London, he obtained the M.R.C.S. Eng. in 1863 and the L.R.C.P. Lond. in the following year. He was elected a Fellow of the Royal College of Surgeons of England in 1894. For many years he was senior surgeon at the David Lewis Northern Hospital (of which he subsequently became consulting surgeon), an honorary surgeon to the Liverpool Royal Infirmary Lock Hospital, and assistant surgeon at the Liverpool Eye and Ear Infirmary. He was an ex-President of the Liverpool Medical Institution.

SPINAL ANÆSTHESIA AND THE ACUTE ABDOMEN.

To the Editor of THE LANCET.

SIR,—May I endorse the plea for spinal stavaine as the anæsthetic of choice in most acute abdominal operations made by Mr. Percival Cole in your issue of Oct. 7th? It is a great gain for the surgeon to have a completely flaccid abdominal wall and quiet thoracic respiration, when the patient's life may depend on delicacy of technique and freedom of access to all parts of the peritoneal cavity. It is a gain, too, to have little or no post-operative vomiting and to be able to give fluids by the mouth from the time of operation. The cutting off of all afferent stimuli during operation prevents any nerve shock, and it is a far more effective way of realising Crile's ideal of "anoci-association" than is the infiltration method used by Crile himself. But, above all, the method is indicated because of the reduced tendency to post-operative intestinal paralysis.

In a paper read before the Manchester Medical Society on Nov. 5th, 1913 (and published in the *Medical Chronicle*, January, 1914) I drew attention to the fact that under spinal anæsthesia in cases of general suppurative peritonitis the small intestine may be seen at operation in active peristalsis, and the bowels often act on the table, owing to the abolition of the inhibitory reflex through the splanchnic nerves, which arise from the sixth dorsal to first lumbar spinal segments. I urged the superiority of this method to general anæsthesia, in which the splanchnic inhibitory reflex remains active and all the traumatic stimuli of the operation add their paralysing influence to that of the peritonitis. My subsequent experience of acute abdominal work has fully borne out this contention, and I am convinced that in many grave abdominal emergencies spinal as against general anæsthesia is a life-saving procedure.

There are, I believe, two stages in the intestinal paralysis of acute peritonitis. The first is the splanchnic reflex inhibition of movement, which is, surgery apart, a protective mechanism and Nature's prophylactic against diffuse infection. The second and terminal stage is a direct poisoning of the neuro-muscular tissues of the bowel wall. When this latter stage is fully developed recovery is hopeless. In this condition the bowel when exposed under spinal anæsthesia lies motionless, in contrast to its active writhing movements when seen in the earlier stage, and I believe that a fairly accurate idea of the post-operative prognosis can be founded on these facts.

In technique I differ somewhat from Mr. Cole. I have not seen any sufficient reason to give up Barker's heavy solution, which I find both rapid and constant in action, and readily controlled in its extent. I do not now often fail to procure anæsthesia up to the costal margin when required, and I have frequently used the method in perforated gastric or duodenal ulcer or operations on the gall-bladder without trouble. Provided that the neck is flexed to protect the phrenic nerves, the legs can from the first be raised higher than the trunk and after 15 minutes the Trendelenburg position can safely be used.

Mr. Cole's method of blindfolding seems to me likely to increase the fears of a nervous patient. I rely on the preliminary dose of morphia and a screen across the patient's chest shutting off the operation, and if the patient is inclined to be nervous a little ether inhaled occasionally keeps him in a drowsy condition, short of the stage of excitement, and has the additional advantage of stimulating the heart and respiration. I always inject eucaine or novocaine intradermically at the site of puncture with a fine hypodermic needle before inserting the spinal needle, and I make the injection myself, while the anæsthetist regulates the level of the patient and decides whether or not to give a little ether.

The technique of spinal anæsthesia is certainly difficult to acquire, but the method becomes far easier and more reliable with experience and will, I believe, ultimately win much wider favour than it at present enjoys.

I am, Sir, yours faithfully,

Manchester, Oct. 9th, 1916.

JOHN MORLEY.

THE PREPARATION OF STABLE COLLOIDAL ANTIMONY.

To the Editor of THE LANCET.

SIR,—The use of colloidal metals in the treatment of bacterial diseases is getting more and more extensive and has given rise to many brilliant results. The remarkable trypanocidal properties possessed by antimony, its specific action against the Leishmania, and the fact that in the colloids generally the ratio dosis curativa : dosis tolerata is very low, make it desirable to prepare a stable solution of colloidal antimony. The Svedberg Company has obtained the isobutyl-alk-sol of colloidal antimony by a method similar to that of preparing colloidal arsenic. The Svedberg's colloidal antimony is brownish-red by transmitted light and black by reflected light.¹

There is mention made of the preparation of this drug in the *Chemist and Druggist* (vol. i., 1913), but so far as I am aware, none of the big manufacturing chemists in England are able to supply it. The reference in the *Chemist and Druggist* is probably to some colloidal compounds of antimony which have been prepared. Experiments conducted by Martindale on the chemical production of colloidal antimony have been unsuccessful.² The Svedberg's colloidal antimony was very unstable and was precipitated within a short time after its production, and must therefore be more or less useless for therapeutic purposes on a practical scale.

Our first experiments were performed with ethyl alcohol. It was found that no colloidal solution of the metal could be obtained by passing sparks from an induction coil through coarse metallic antimony under ethyl alcohol. The method of passing a feeble current through this medium was tried but without success. The most successful medium was found to be chloroform, from which the colloid is obtained in fair concentration and from which solid colloidal antimony can be secured by evaporating the medium.

The details of the preparation are as follows. The apparatus consists of a fair-sized induction coil worked by an 8-volt accumulator. The electrodes, made of aluminium foil, are dipped in chloroform, into which are added coarse particles of metallic antimony freed from dust of antimony by sifting. On passing sparks through this medium some of the antimony passes into a powdery state and some goes into solution. On distilling off the solvent we obtain a tar-like substance, having a peculiar smell. The substance can be dried in a desiccator or in air and even heated gently over the Bunsen burner, but apparently does not undergo much change, as it is freely soluble in chloroform after such treatment.

The colloidal solution of antimony is brownish-red by transmitted light and black by reflected light, being in this respect similar to the Svedberg's colloid. It presents the Tyndall phenomenon. The colloid obtained in this way seems to be a very stable substance, and in this respect differs from the Svedberg's colloid. The therapeutic use of the colloidal metallic antimony has already been described in the *Indian Medical Gazette* (May, 1916). Further observations on the use of this drug in the same disease have shown similar beneficial results.

I am, Sir, yours faithfully,

UPENDRA NATH BRAHMACHARI, M.A., M.D., Ph.D.,

Raj Bahadur; Teacher of Medicine at the Campbell Medical School, Calcutta.

August 18th, 1916.

THE DIAGNOSIS OF TUBERCULOSIS BY TUBERCULIN.

To the Editor of THE LANCET.

SIR,—I venture a criticism on a point of technique raised in Dr. H. A. Ellis's excellent article on diagnosis by tuberculin in your issue of Oct. 7th. If the successive dilutions are made within the syringe the amount contained in the nozzle after the plunger has been brought to the tenth mark as directed by Dr. Ellis is too great to be disregarded. It is doubtless variable with the pattern of syringe used, but I have found it several times to be about one-third of a division. In such case the dilutions prepared according to Dr. Ellis's method, nominally 1 in 10, 1 in 100, 1 in 500, would be actually 1 in 7.5, 1 in 56, 1 in 211.

¹ Ber. 38, 3615-3620, 1906, and Megus' "Inorganic Chemistry."² Extra Pharmacopœia, 1915, sixteenth edition.

I am inclined to doubt the wisdom of trusting to an air-bubble for the thorough mixing of the contents of a long, narrow syringe. In such bubbles move very slowly and grudgingly. Why not pass a teaspoon through the flame of a spirit lamp and discharge and refill the syringe into and from it several times? I am, Sir, yours faithfully,
Coventry, Oct. 16th, 1916. A. F. BILL.

THE AGGLUTINATION OF MENINGOCOCCI IN RELATION TO CURATIVE SERUMS.

To the Editor of THE LANCET.

SIR,—The treatment of epidemic cerebro-spinal meningitis by intrathecal injections of immune serum has given somewhat uncertain results during the past two years in Great Britain. On this account the findings of an investigation into the agglutinative properties of divers serums, despite the fact that these serums were only tested against two strains of meningococci, may be of interest to those concerned with the treatment of this disease.

Since the microscopic test in the case of non-motile organisms allows at least the possibility of leaving something to imagination, I made use of Dreyer's macroscopic method of testing for agglutination. In this method positive reactions are marked by a definite flocculent deposit and by a clearing up of the supernatant fluid. As a control the homologous serum for each strain of meningococci was used. In addition to this a normal serum and also the serum of a man who had recovered from the disease 12 months previously were employed.

From the spinal fluid of two patients, Q. and W., under the care of Deputy Surgeon-General Robert Hill, C.V.O., at the Royal Marine Infirmary, Deal, pure cultures of a Gram-negative diplococcus, growing at 37° C., but not at 22° C., and fermenting glucose-litmus-peptone-ascitic water, but not saccharose litmus-peptone-ascitic water—the diplococcus meningitidis—were isolated. Incidentally these cultures retained their characteristics through many subcultures. In testing the agglutinating properties of the serums on these two strains of meningococci an emulsion of a 16-hours growth was employed. The serums tested were diluted 1 in 10, 1 in 15, 1 in 25, 1 in 50, 1 in 125, and 1 in 250.

Meningococci from the patients Q. and W. were not agglutinated by normal serum, by serum from a patient who had recovered 12 months ago, by the antimeningococcus serum of the Wellcome Physiological Research Laboratories (A. 1289 D.), or by the following antimeningococcus serums from the Pasteur Institute of Paris—(3636) Gordon strain 1, (3639) Gordon strains 2 and 3, and (3635) monovalent, all prepared in February, 1916—in any of the above dilutions.

The meningococci from the patient Q. were not agglutinated by serum from the patient W. in any of the above dilutions. They were agglutinated by their homologous serum from patient Q. and also by the polyvalent serum of the Pasteur Institute (January, 1916) in dilutions of 1 in 10, 1 in 15, and 1 in 25. Lastly, this strain of meningococci was agglutinated by the antimeningitis serum of the Rockefeller Institute, New York (17/11/15) in dilutions from 1 in 10 to 1 in 125.

Meningococci from the patient W. were not agglutinated by serum from the patient Q. or by the polyvalent serum of the Pasteur Institute in any of the foregoing dilutions. They were agglutinated by their own homologous serum from the patient W. in dilutions from 1 in 10, 1 in 15, and 1 in 25, and they were agglutinated by the serum of the Rockefeller Institute in dilutions from 1 in 10 to 1 in 250.

This investigation was repeated on three occasions, and the results remained constant. The value of the serum prepared at the Rockefeller Institute, New York, as judged by the agglutination of these two strains of meningococci, is very apparent, and it may be suggested that early lumbar puncture, followed by intrathecal injection of this serum, should lead to results as brilliant as those originally achieved by Flexner.

Of the two cases to which reference has been made, both fulminant in type at the onset, one (W.) has made a complete recovery. This patient had an intrathecal injection of Flexner's serum (40 c.c.) six hours after the onset of the disease. The other patient (Q.) died after three months' illness. He received an early intrathecal injection of one

of other serums enumerated, but did not have Flexner's serum (40 c.c.) until the eighth day of his illness.

I am, Sir, yours faithfully,
Harley-street, W., Oct. 10th, 1916. HALLIDAY SUTHERLAND.

"CLERGYMEN'S SORE-THROAT."

To the Editor of THE LANCET.

SIR,—It is now over 30 years since I first asked myself why we speak of chronic pharyngitis and laryngitis produced by over-speaking, as "clergymen's sore-throat" and not as barristers' sore-throat. Why is this condition so rarely seen in barristers who use their voices more than clergymen, and in stuffer atmospheres? On thinking over the matter the only difference I could perceive between a clergyman's and a barrister's speaking was that a clergyman spoke *down* to his congregation, and a barrister spoke *up* to the judge, the former thus pressing on his larynx and causing congestion thereof, whereas the barrister had his larynx and throat in a normal position, or rather in a hypernormal position. From that time I have always advised such cases to speak looking *up* to their audience and never *down*. I have used no local applications or treatment except to rectify a condition such as granular pharyngitis, but where necessary have suggested a rest of voice for two or three months.

In all cases this plan has been successful. I will only quote one case, an American lady with complete loss of her speaking voice; she was a public lecturer and had had to relinquish her calling, no treatment having benefited her. After three months' rest of voice she resumed her occupation, now 12 years ago, and has never since had loss of voice. During this period she had made no alteration in her manner of public speaking, except that she has declined to use any buildings which involved speaking *down* to her audience, and has therefore always spoken looking *up* from the well of a theatre.

I was much interested a few years ago to see Professor Keith's statement that the human voice would never have become developed had we not first attained the upright posture, which, it seems to me, bears out the *raison d'être* of the treatment mentioned above.

I am, Sir, yours faithfully,
Weymouth-street, W., Oct. 17th, 1916. GEO. STEELE-PERKINS.

THE ROYAL ARMY MEDICAL CORPS GAZETTES.

To the Editor of THE LANCET.

SIR,—The Royal Society of Medicine has received from time to time a few odd numbers of these Gazettes, probably sent to us by Fellows at the front, and I would like with your kind permission to invite those responsible for the publication of these Gazettes that they would endeavour to send to us complete sets, which would be bound and carefully preserved in our library. I need scarcely enlarge on the interest that will attach to such a collection in the years to come, and as, under the conditions that prevail at the front, it is not likely that many complete sets will be preserved, they are sure to become exceedingly scarce and probably unobtainable after the war.

I should be very grateful to any who, seeing this letter, will help me in trying to preserve a complete set of all the Gazettes in this library.

I am, Sir, yours faithfully,
J. Y. W. MACALISTER.
Royal Society of Medicine, 1, Wimpole-street, W.,
Oct. 14th, 1916.

MEDICAL SOCIETY OF LONDON.—An incident of historical interest is the removal of the fine terra-cotta plaque which was presented by the founder of this society, Dr. John Coakley Lettsom, in 1778, from the original meeting house, No. 3, Bolt-court, Fleet-street, and its installation in the present home in Chandos-street, Cavendish-square. The central figure of the plaque represents the Isis of Sais, the fabled revealer of the mysteries of Nature and the presiding genius of medicine. It is flanked on either side by a sphinx, symbolising mystery, while a serpent, emblematic of eternity, bears the inscription, in Greek, "I am whatever is or has been or will be, and no mortal has hitherto drawn aside my veil."

The War.

THE CASUALTY LIST.

THE following names of medical officers appear among the casualties announced since our last issue :—

Killed.

Capt. A. W. Venables, R.A.M.C., was a student at St. Mary's Hospital, London, and qualified in 1913. He was in practice at Cricklewood before joining the R.A.M.C. He received his captaincy in September last.

Died of Wounds.

Lieut. W. S. Lacey, R.A.M.C., was a student at Guy's Hospital, London, and qualified in 1912, having previously received the L.D.S. R.C.S. Eng. in 1903. He was in practice at Hertford before joining the R.A.M.C.

Died.

Col. B. B. Grayfoot, C.B., I.M.S., received his medical education at Edinburgh University and qualified in 1885. He thereupon joined the Indian Medical Service, and was gazetted captain in 1886 and colonel in 1912. He held the appointment of Assistant Director of Medical Services in India, and was appointed C.B. in January of this year.

Wounded.

Capt. H. B. German, R.A.M.C., attached Leicester Regiment.
Capt. W. L. Hutton, Canadian A.M.C.
Lieut. E. E. T. Nuthall, R.A.M.C.
Capt. L. D. Stott, R.A.M.C.
Lieut. R. N. Craig, R.A.M.C., attached Yorkshire Regiment.
Lieut. H. F. Johns, R.A.M.C., attached Leicester Regiment.
Capt. R. J. Rogers, R.A.M.C., attached Middlesex Regiment.
Lieut. F. A. Anderson, R.A.M.C., attached Royal Irish Rifles.
Capt. F. L. P. G. Bennett, R.A.M.C., attached Shropshire Light Infantry.
Lieut. G. J. McGorty, R.A.M.C., attached Highland Light Infantry.
Capt. J. C. Pyper, R.A.M.C.
Lieut. A. J. R. Taylor, R.A.M.C.

MENTIONED IN DESPATCHES.

In a despatch received from Lieutenant-General Sir Percy Lake, Commander of the Forces in Mesopotamia, and describing the final operations for the relief of Kut-el-Amara, the following reference to the medical staff appears :—

The energy and devotion to duty shown by the personnel of the medical services deserve commendation. Overworked and undermanned as they were during the advance in January—for the greater portion of the medical organisations then in the country had been shut up in Kut, and the medical units of the 3rd and 7th Divisions had only begun to arrive—they did their utmost with the means at their disposal to alleviate the sufferings of the sick and wounded. With the arrival in February of the first river hospital ship, *Sikkim*, and a steady increase in personnel, their power of dealing with the situation was considerably improved, as the action on March 8th showed. No report on the medical services would be complete without reference to the splendid services rendered by Mr. T. A. Chalmers, of Assam, who brought out, and himself drove, his specially designed motor-boat *Arcl*. He spent his whole time, frequently under fire, in conveying sick and wounded between collecting stations, field ambulances, and river hospital craft in a manner which no other boat in our possession could have imitated.

DEATHS AMONG THE SONS OF MEDICAL MEN.

The following sons of medical men must be added to our lists of those who have fallen during the war :—

Trooper G. L. Hardwick, Canadian Cavalry, third son of Dr. F. S. Hardwick, of Charing, Kent.
Lieut. R. Davison, Liverpool Regiment, only son of Dr. J. R. Davison, of Belfast.
Second Lieut. N. de Havilland Hall, Suffolk Regiment, younger son of Dr. de Havilland Hall, of Wimpole-street, W.
Second Lieut. L. H. Spreat, Royal Horse Artillery, younger son of Mr. F. A. Spreat, F.R.C.S., of Whetstone.
Second Lieut. H. P. Dudley, 3rd Leinsters, attached Royal Irish Regiment, third son of the late Dr. H. M. Dudley, of Queen's County, Ireland.
Lieut. H. St. B. Sydenham, Devonshire Regiment, only son of Dr. G. F. Sydenham, of Dulverton, Somerset.
Second Lieut. H. C. Crichton, Manchester Regiment, youngest son of Dr. G. Crichton, of South Kensington.
Second Lieut. A. C. MacCormick, Argyll and Sutherland Highlanders, elder son of Sir A. MacCormick, M.D., of Sydney, Australia.
Capt. N. A. Browning-Paterson, Royal Flying Corps, younger son of Dr. A. Browning-Paterson, of Shepherd's Bush.
Second Lieut. L. C. Kidd, Royal Flying Corps, second son of Dr. H. C. Kidd, of Bromsgrove, Worcestershire.

OBITUARY OF THE WAR.

ARTHUR NIMMO WALKER, B.A., M.D., B.C. CANTAB.,
LIEUTENANT-COLONEL, ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel A. N. Walker, who was killed at the front on Sept. 24th, was second son of the late Dr. George Edward Walker, founder of St. Paul's Eye Hospital, Liverpool. He was educated at Liverpool College and Queens' College, Cambridge, and after qualifying in 1898 was house physician to the Liverpool Royal Infirmary and assistant lecturer on anatomy at the University before he began to devote himself exclusively to ophthalmic surgery, in which his father had been distinguished before him. Besides his surgeoncy at St. Paul's Hospital, he was ophthalmic surgeon to the David Lewis Northern Hospital and to the School for the Indigent Blind, as well as one of two ophthalmic surgeons under the Liverpool Education Committee in connexion with the scheme for the treatment of school children. Dr. Walker made numerous contributions to the literature of his subject, among the most important being the record of a novel and successful experiment in the control of ophthalmia neonatorum, published in our columns in 1908. Dr. Walker served in the South African War, and later, on joining the Territorial Army, was appointed to the command of a battery of West Lancashire Artillery. On the outbreak of war he transferred to the Royal Army Medical Corps and went to France in August, 1915.

Mr. Frank Jeans writes :—"To those few who, like myself, knew Arthur Nimmo Walker more than intimately his loss is irreparable, and I doubt whether his large circle of friends ever assessed his worth at its true value. He had all the qualities which command affection and respect—I mean a sense of duty, loyalty, and chivalry. Furthermore, his sense of humour, which was particularly charming, prevented the serious qualities from making him dull. These characteristics, though not the kind that necessarily make for a meteoric success, were bound to have made him, by his expert knowledge and skill in his special work, a leader of his profession. It was characteristic of him that the subject he gave his heart to was ophthalmia neonatorum, a disease never seen in wealthy patients, and his work in this direction will in the future be regarded as one of the landmarks of preventive ophthalmic surgery. Arthur Walker was one of the few men of our own generation whom we felt could be consulted about general matters with the absolute certainty of getting advice which was wise and ethically sound, and above all disinterested. He was always thinking of someone else—now his patients, now his colleagues, now his family. Rarely did it occur to him that there was such an individual as Arthur Walker to be considered."

ARTHUR ANDERSON MARTIN, M.D., F.R.C.S. EDIN.,
MAJOR, NEW ZEALAND MEDICAL CORPS.

Major A. A. Martin, who died on Sept. 17th of wounds received on active service, at the age of 40 years, was born in Otago, New Zealand. After a brilliant career as a scholar and prizeman, he graduated with honours at Edinburgh University in 1900, and was then house surgeon at the Hospital for Sick Children, Great Ormond-street, and senior house surgeon at the Sheffield Royal Hospital. He served as a civil surgeon in the South African Field Force, 1901-02. At the beginning of the present war he joined the Royal Army Medical Corps, and went through the battles of the Marne and Aisne, being mentioned in despatches for gallant conduct in the field. He was then for a time surgical specialist to No. 6 General Hospital, Rouen. In February,

1916, he joined the New Zealand Medical Corps, and during the seven months until his death served his corps with great personal devotion.

Major Martin will be remembered at Palmerston, New Zealand, as a practitioner who was a generous and helpful friend to a wide circle of patients. He contributed a number of surgical notes to medical journals, and as the author of "A Surgeon in Khaki" was widely known as a frank critic of men and affairs.

THOMAS CAMERON HOUSTON, M.B., CH.B. GLASG.,
CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain T. C. Houston, who was killed on active service on August 25th, was a native of Muirkirk, where he received his

early education, and later at Kilmarnock Academy. His medical course was taken at Glasgow University, where he graduated M.B., Ch.B. in the summer of 1915, at once offering himself for service in the Royal Army Medical Corps. He was attached to the Yeomanry at Selkirk, where he was a favourite with the men, sharing in all their sports. In July of this year his request for a place at the front was granted, and in the following month he was killed by a

shell along with two officers who were standing with him.

A medical friend who knew Captain Houston intimately writes of him as a delightful companion, a keen student, full of eagerness and enthusiasm for his work. "He was intensely interested in all laboratory work. I feel sure that if he had been spared he would have done something special in research."

THOMAS STRAIN, M.D. GLASG., D.P.H. CANTAB.,
CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain T. Strain, who died on active service on Sept. 16th at the age of 31, was the youngest son of William Strain, of Buarbrae, Wishaw, Scotland. From Hutchison's Grammar

School, Glasgow, he entered Glasgow University, graduating M.B., Ch.B. on his twenty-first birthday. He then spent a year visiting Cape Colony, Natal, Transvaal, and Orange River Colony. On his return he devoted himself to public health work, taking the D.P.H. of Cambridge in 1908. He also graduated M.D. Glasg. in 1910. Of public health appointments he was in succession the resident medical officer at Enfield and Edmonton Isolation Hospital, assistant

medical officer of health for Ayrshire, medical officer of health for Barnes and Mortlake, and just before joining the Army he was medical officer of health for Heston and Isleworth. While at the front he was twice mentioned in despatches.

One of his colleagues writes of Captain Strain: "I knew him as the first resident medical officer to this hospital, and I soon found out his sterling qualities. Method was his mainspring, and he quickly reduced his work to manageable dimensions, although immediately after taking up the duties we had to deal with a very large outbreak of diphtheria.

His mental equipment was of a high order and with his genial ways and kindness of heart he would have gone far in the particular branch of the profession which he had chosen." Captain Strain leaves a widow and two children.

GEORGE HUNTLY WOOD, M.B., B.S. DURH.,
CAPTAIN, NEW ZEALAND MEDICAL CORPS.

Captain G. H. Wood, who died at Suez on August 11th from wounds received in the recent fighting, was son of the late George Wood, a well-known shipmaster of North Shields. Educated privately, he

entered the merchant service, securing an extra-master mariner's certificate when he was 23. He was then for a time chief officer with the White Star Line. At the age of 30 Huntly Wood became interested in surgery and determined to qualify as a medical man. He was a student at the Newcastle-on-Tyne Medical School and on qualifying in 1909 held several resident appointments at the Royal Victoria Infirmary before emigrating to New Zealand,

where he built up a considerable practice at St. Andrews, South Canterbury. When war broke out he offered his services to the New Zealand Expeditionary Force and remained with it until the time of his death.

THE DIET OF THE MUNITION WORKER.

The soldier and the sailor expect to have their food provided for them on a dietary arranged for their particular needs, and now that the average high price of food¹ has rendered a nourishing and economical diet for the civilian population a matter of primary importance, the munition worker is also beginning to be dieted according to his or her special requirement. In many places canteen meals are provided where the workers come from afar; in others where accommodation was completely lacking special hostels have been erected. Dr. Leonard Hill, on behalf of the Health of Munition Workers Committee, has recently made an investigation into the cost and the nutritive value of the food supplied, and the information obtained is embodied in a report which has just been published as the second Appendix to Memorandum 3 (Industrial Canteens). He lays down the principle that the amount of food taken should be regulated solely by the loss of energy it is required to replace, and adds that fortunately the chief foodstuffs really provide all the nourishment that is requisite and consistent with health, probably better than the more highly flavoured and expensive foods which artificially stimulate the appetite. Of these cheaper foods Dr. Hill gives a list as follows: Bread, margarine, porridge, milk, herrings, cheese, beans, cabbages, oranges, and the cheaper kinds of meats. He estimates that the energy required by a man engaged in fairly light munition work is about 3500 calories of the food as purchased. The composition of canteen meals was made the subject of careful analysis, the method being as follows in each case:—

The ingredients were all thoroughly mixed after weighing each separately, so that dietaries could afterwards be constructed from the weights. An aliquot part of the intimate mixture was thoroughly dried and weighed. In the dry material protein was determined from a nitrogen estimation, the fat by ether extractions in a Soxhlet's apparatus, the ash by burning and weighing, and the carbohydrate by difference. In this way the amounts of dry protein, fat, and carbohydrate respectively in the meal were obtained, and from these the calorie value was calculated.

¹ According to the recent issue of the Board of Trade Labour Gazette the average increase in the retail price of food since the commencement of the war is 68%, of which 20% represents the rise during the last twelve months.

The average canteen dinner was found to be a good one, containing an energy value of about 1000 calories well distributed among the amounts of protein, fat, and carbohydrate. The cost of such a meal varied from 5d. to 9d., comparing very favourably with the sum of 1s. 2d. or 1s. 5d. required to purchase practically the same meal at a students' club and popular restaurant respectively. The meals brought from home by the workers were also submitted to analysis. The workers from home whose meals were obtained were not asked beforehand to bring a sample meal, but were interrogated at the entrance gates and asked to exchange the contents of their baskets for a sum ample to buy a meal at the canteen. In the case of men these meals were found to be adequate, but in the case of girls there was very wide variation, from 300 up to 1100 calories. As for the latter the breakfast meal before starting work often consists of white bread and boiled tea. The lower values connote definite under-nutrition. An investigation was also made at a well-managed hostel where each worker was at liberty to eat as much as he or she desired. The weekly cost price of food at this hostel in March, 1916, worked out at 15s. 2d. per man and 11s. 10d. per woman, the number of calories being respectively 3900 and 3000; the same figures were obtained from actual analysis and from data supplied by the management. The Memorandum ends with a table of simple daily meals designed to secure a well-balanced dietary for the assistance of caterers to munition workers. Each of the five daily diets given contains about 3000 calories at a cost of 24d. to 26½d., on the basis of prices ruling in April, 1916. The reading of the Memorandum leaves the impression that the best thought is being brought to bear on the problem of feeding the munition worker. Although there is nothing in the investigation which is very new, a valuable degree of practical certainty is being reached in regard to the minimum adequate diet required for a certain type of manual labour. No attempt has been made to modify drastically the ordinary diet of the people concerned. The herrings, cheese, and beans already mentioned do not appear very extensively in the dietaries. The Briton is naturally conservative in regard to what he eats and drinks, and there is fortunately no immediate imperative need for drastic change, but we think the opportunity should not be lost of demonstrating once and for all to the manual workers of this country that a perfect diet need not consist principally of meat and potatoes.

WAR RECORD OF THE LONDON MEDICAL SCHOOLS.

—We have now received the figures for Guy's Hospital, which should be read in conjunction with those already given (THE LANCET, Sept. 23rd, p. 579) for the other London schools.

Guy's.—Joined, 1318. Died, 42. Honours: C.B., 3; C.M.G., 5; M.C., 12; D.S.O., 10; Order of St. John of Jerusalem, 2; Order of St. Sabe (Fifth Class), 1; Croix de Guerre, 1; Other distinctions, 2; Mentioned in Despatches, 46.

PRINCESS HENRY OF BATTENBERG'S HOSPITAL.

Dr. A. J. Rice-Oxley, medical director and physician to Princess Henry of Battenberg's Hospital for Officers, has received a gratifying and well-deserved acknowledgment from the personnel of the hospital of the value and qualities of his services as a colleague and administrator. This took the form of a signed address, and ran in these words:—

To A. J. RICE-OXLEY, Esq., M.D., M.R.C.P., Medical Director and Physician to Her Royal Highness Princess Henry of Battenberg's Hospital for Officers.

30, Hill-street, Mayfair, W.

SIR,—We, the undersigned members of the medical and nursing staff of Princess Henry of Battenberg's Hospital, desire to place on record our appreciation of your services to this hospital during the two years in which it has been in existence, from August 31st, 1914, to August 31st, 1916. Your unfailing courtesy and kindness to all, and your great skill and untiring energy and labour in, and on behalf of, the hospital have both endeared you to us and encouraged us to work together for the common good, thus assisting to make this hospital, we believe, to be one of the most successful of its kind and one of the happiest in which to work.

We trust that under your direction this hospital may continue its good work until in more peaceful times our services are no longer required.

The address was signed by Princess Henry of Battenberg and by the medical officers and nurses of the institution, including Lieutenant-Colonel A. S. Woodwark, R.A.M.C., the Officer in charge of Officers' Hospitals, and Colonel W. Allan May, R.A.M.C., the President of the Special Medical Board.

FOURTH SOUTHERN GENERAL HOSPITAL (T.F.).—

This hospital is to be enlarged by the addition of Camel's Head School, Devonport. The Fourth Southern General Hospital (T.F.) will now comprise the Ford House Hospital and auxiliary establishments at Salisbury-road, Hyde Park-road, and Camel's Head. Lieutenant-Colonel H. W. Webber is in command.

MONTENEGRIN RELIEF FUND.—

A central office for the Montenegrin Red Cross and Relief Fund has been opened at 11, Victoria-street, S.W. The fund, which has been registered under the War Charities Act, sends food and hospital necessities to Montenegro, and donations are urgently needed. They may be sent to Lady Roper Parkington at 58, Green-street, Park-lane, W.

HOSPITAL FOR WOUNDED OFFICERS.—

A new Russian hospital for the accommodation of British wounded officers was opened in temporary premises in South Audley-street, Mayfair, W., by the Prime Minister on Oct. 17th. As we announced last week, the donors are M. Mouravieff-Apostol, Chamberlain of the Russian Court, and his wife. Dr. C. Gould-May, who has been employed at the Anglo-Russian Hospital in Russia, will be in medical charge; the consulting staff being: physician, Dr. Wilfred J. Hadley; surgeons, Mr. R. P. Rowlands and Mr. Ivor Back; ear, Mr. H. J. Marriage; throat and nose, Mr. W. G. Howarth; radiographer, Mr. C. Gouldesborough; anaesthetist, Mr. G. A. Jones; and bacteriologist, Mr. W. B. Weir.

WAR HOSPITALS IN INDIA.—

The Indian Council of the St. John Ambulance Association have issued another special war circular appealing for money to "enable them to meet a demand just received from the military authorities for a large supply of supplementary equipment for certain hospitals which are being opened in India for sick and wounded arriving from the front." Commenting on this appeal, the *Pioneer* says that the time would seem to have come when the Government should reconsider their position in connexion with these war hospitals, and this is the feeling generally. Not even the most ardent advocate of economy would object to the expenditure of public money on improving the amenities of life in the new hospitals in India. Liberal outlay in this direction would indeed be generally welcomed; and, if necessary, orders should be passed which would meet possible technical objections by the Accounts and Audit Departments. The Government of India may or may not have been justified in framing a war budget of modest dimensions; it will certainly not be justified in extending the policy of financial caution to the case of the wounded, especially as the articles immediately required can apparently be bought for hard cash in the open market.

THE Hospital Unit recently sent out by the

British Red Cross Society and the Order of St. John, under the command of Dr. F. G. Clemow, C.M.G., has arrived at Galatz, Rumania.

TRAFALGAR DAY will be celebrated at the

headquarters of the British and Foreign Sailors' Society, Commercial-road, London, E., by a reception and concert for wounded sailors from the adjacent hospitals.

THE LATE EDITH CAVELL.—

In Paris on Oct. 11th, the first anniversary of the death of the heroic English nurse, a hospital and school bearing her name was opened as a memorial by M. Justin Godart, one of the Under Secretaries of State for War. The hospital contains 100 beds, but it is only a temporary building pending the erection of more extensive premises by public subscription. Sir George Frampton has presented the hospital with a bust of Miss Cavell. Professor Hartmann and Madame Curie are members of the staff. On the same day a memorial was unveiled in the nurses' dining-room at the Shoreditch Infirmary, where Miss Cavell was at one time assistant matron. Dr. C. Addison, who was present at the ceremony, paying a tribute to the noble example of Miss Cavell's life, said that the same unselfish motive which had inspired her life had stimulated many workers and business men at home. The execution of the most cherished hope of Miss Cavell—namely, that homes of rest for nurses should be established, has taken a practical form, as has already been announced. The honorary treasurer of the movement is Mr. Charles Campbell McLeod, 10, Lime-street, London, E.C., and the honorary secretary Mr. Wallace Braby, 25, Victoria-street, London, S.W.

Medical News.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At the quarterly examination in Practical Pharmacy held on Oct. 12th the following candidates were successful:—

Margaret Gladys Best, London School of Medicine for Women; James Bassett Brash, St. Bartholomew's Hospital; John William Chadwick, Manchester University; Jane Crawford, London School of Medicine for Women; Dennis Reginald Curnock, Charing Cross Hospital; Albert William Abell Davies, Guy's Hospital; Herbert Davies and Sidney Richard Eccles Davies, St. Bartholomew's Hospital; Martin Joseph de Lemos, King's College Hospital; William Allison Drake and Mohammed Nour Eldin, St. Bartholomew's Hospital; Leonard Henry Brittan Evans, Cambridge University and Guy's Hospital; Edgar Thomas Flood, St. Mary's Hospital; Edwin Stowell Gawn and William Francis Gawn, Liverpool University; Geoffrey Herbert Gidlow-Jackson, Cambridge University and London Hospital; Melik Gurgis, University College Hospital; Edward Francis Strathearn Gordon, Cambridge University and St. Bartholomew's Hospital; Thomas Sacheverell Greenaway, Westminster Hospital; Reginald Rowley Halsall, Manchester University; Douglas Vernon Halstead, Guy's Hospital; John Hollings, London Hospital; Geo. Geo. Raymond Hubbard, Guy's Hospital and private study; John Haslam Johnston, Charing Cross Hospital; Thomas Edward Moody-Jones, University College, Cardiff; Geoffrey Burman Lowe, Cambridge and Birmingham Universities; Kenneth Alexander Ingleby Mackenzie, Oxford University and St. Bartholomew's Hospital; Arthur Harry Morris, Bristol University; Hussein Noorat, St. Bartholomew's Hospital; Aron Ber Pastel, Paris and Charing Cross Hospital; Walter Erichsen Powell, Charing Cross Hospital; Charles Farrell Rainer, London Hospital; William Sleeman Roberts, St. Mary's Hospital; Edith Marjorie Rooke, London School of Medicine for Women; Ronald Cunliffe Shaw, Manchester University; and Greta Isabel Yeoman, London School of Medicine for Women.

UNIVERSITY OF GLASGOW.—The following results of examinations at Glasgow University are announced:—

DEGREES OF M.B., CH.B.

The following have passed in the subjects indicated—**A., Anatomy; P., Physiology; M., Materia Medica and Therapeutics; Path., Pathology:**—

Roderick Bethune, Path.; Alexander Black, Path.; William George Burns, A. P.; Michael John Cahalan, Path.; Malcolm Chalmers, Path.; John Parker Chisholm, M. Path.; Hugh Auld Cochrane, Path.; Alexander Conner Connell, M.; Edward Mitchell Erskine Cumming, M.; Archibald Brown Smith Drysdale, Path.; William Edgar, M.; Basil William Henry Fergus, Path.; Duncan Finlayson, Path.; James Paton Fleming, Path.; Allan Donald Fraser, P.; George Keith Fulton, M. Path.; James Biggam Douglas Galbraith, M. Path.; Matthew Forsyth Gibson, A. P.; Francis Denis Gillespie, A. P.; Adam Smith Goudie, Path.; James Smith McLean Gray, Path.; John Forrest Hamilton, A. P.; John Gordon Harrower, Path.; Andrew Henderson, Path.; James Charles Hendrie, Path.; Morris Hyman, Path.; John Irving, Path.; Robert Paterson Jack, M. Path.; James Patrick Kilty, Path.; Chung Un Lee, A. P.; Douglas Marshall Lindsay, P.; Jacob Lipschitz, Path.; William Wilson Lundie, M.; Duncan MacColl, M.; Robert Tweedie McGibbon, Path.; Thomas McGowan, Path.; James Athole Campbell MacGregor, Path.; John William Mackay, Path.; William Stanley Lones McLeish, Path.; William McLinden, Path.; Findlay Kerr Macmillan, M.; John Spence Melghan, A. P.; John Muil Melvin, Path.; William Duff Miller, Path.; William Napier, Path.; Bryce Frood Niblock, M.; Isaac Ladipo Oluwale, M. Path.; John Bernard O'Neill, M.; Norman Bligh Peacock, Path.; George Pearson, Path.; Robert James Peters, Path.; Thomas Poole, M.; Rahmat Ullah Qureshi, M.; Andrew Riddell, M. Path.; Samuel Murdoch Riddell, Path.; John Joseph Robertson, Path.; Thomas Stark, M. Path.; Donald Stewart, A. P.; Turner Stewart, Path.; Archibald S. Strachan, Path.; Joseph S. Pat. Adam Stewart, Path.; Adolph Samuel van Colter, M.; James Churchill Vaughan, Path.; William Andrew Walker, M. Path.; Harold Douglas Wallace, Path.; John Allan White, Path.; Thomas McKimming Wilson, Path.; George Macfate Wishart, Path.; and William Young, M. Path.

Women.—Helen Frances Allinson, A. P.; Ellen Davidson Anderson, M.; Grace Hay Anderson, P.; Margharita Mary Lamont Couper, Path.; Grace Anderson Fleming, Path.; Mary Brown Gillespie, M.; Jane Evelyn Hanson, Path.; Janet Whyte Hepburn, Path.; Elizabeth Smith Inglis, P.; Margaret Logan, A.; Elizabeth Cochrane Loudon, Path.; Mary Jessie Macdonald, Path.; Agnes Purcell McGavin, M. Path.; Margaret Turner George, Path.; Maud Elizabeth Drysdale Mackinnon, M. Path.; Margaret Elizabeth MacLaron, A. P.; Caroline Jane MacLennan, A. P.; Margaret Gardner McVey, Path.; Florence Frances Mitchell Milne, Path.; Mercedes Margaret Morton, M.; Georgina Murdoch, A. P.; Elizabeth Park Young Paterson, Path.; Vida Johnston Perry, Path.; Agnes Petrina Routledge, Path.; Eliza Dorothea Sandison, A.; Marjory Mary Scanlan, M. Path.; Jane Elder Shortt, M.; Margaret Marion Catherine Steedman, Path.; Muriel Amy Stowe, A. P.; Dorothea Helen Suttie, Path.; Jean Banks Thomson, A. P.; and Lydia Ida Huber Torrance, Path.

The following have passed in the subjects indicated—**B., Botany; Z., Zoology; P., Physics; C., Chemistry:**—

Alexander Gardner Aitken, B. P.; William Simpson Aitken, B. P.; Daniel Erwin Alley, Z.; Ralph William Sydney Ashby, B.; Alexander Baird, C.; Gavin Haddow Boyd, P.; William Brock, B.; Douglas Brown, B.; Alexander Orr Bruce, B. P. C.; Stewart Caldwell, B. P.; Douglas Hugh Cluterebeck, B. Z.; Archibald Robson Cook, P.; William Davie, B. P.; James Dawson, B. P.; Alexander Smith Dick, C.; James Ferguson Dunn, B.; Andrew

NalSmith Fergus, B. P.; Bruce Paterson Gardner, Z.; Hugh Shaw Dunn Garven, B. P.; Westall Geyer, B. P.; Robert Dick Gillespie, B. P.; Alan Dakers Gowans, B.; Gerald Francis Graham, Z. C.; Ross Alfred Grant, B. P.; Alexander Gray, B.; John Andrew Hamilton, B. P.; George Harvey, Z. C.; Hugh Wardrop Howieson, B. Z. P. C.; Thomas Downie Hunter, Z.; Jack Hurwich, B. P.; Peter Hutchison, B. Z. C.; George Jamieson, Z.; Lennox Matthew Johnston, B. P.; William Macdonald Johnston, B. P.; Hugh Kay, B. P.; David Allison Ker, B. P.; James Arthur Kerr, B. U.; Crawford Alexander Lindsay, B. P.; Alexander Logan, P.; Andrew Logan, B. Z. C.; George M'Alpine, Z.; James Macdonald, P.; John M'Dougall, B. P.; Thomas John M'Kall, B.; George MacKerracher, B. P.; Patrick M'Kay M'Killip, B. P.; Archibald M'Whinney, Z.; Matthew Flindlay Gathrie Main, B. P. C.; Arthur Markson, B. P.; David Melkie, B. P.; Edin Ernest Miller, B. P.; Malcolm James Miller, B. Z.; Peter Milligan, B. P.; John Malcolm Lamont Mitchell, B. P.; William Muir, Z. C.; James Paton Neilson, B. Z. P.; William Guthrie Niblock, Z. P.; Francis Ignatius O'Brien, Z. P.; John Smith M'Laren Ord, B.; Irvine Paterson, B. Z. P. C.; Thomas Core Porter, B. P.; Archibald Rae, B. Z. P. C.; Joseph Francis Reilly, B. P.; Cyril Gladstone Richards, B. P.; William John Brownlow Riddell, B. P.; John James Austin Ritchie, B. P.; Ian Christie Robertson, B. Z. C.; Leopold Harold Salzmann, Z.; Ian MacRae Sandlands, Z. C.; Thomas Stewart Sargent, B. Z. P.; Wilfrid Henry Scott, B. P.; Henry Edmund Seiler, B. P.; John Shanks, Z. C.; Robert M'Dougall Smellie, B. P.; Archibald Gordon Smith, B. P.; Charles Milliken Smith, B.; David Craydon Smith, M. P.; Andrew Snaddon, B. P.; John M'Laughland Straug, B. P.; Charles Noel Temple, C.; James Nisbet Tennent, B. P.; Daniel MacLachlan Thompson, B. P.; Jonathan Robson Turner, B. Z. P. LITERARY INTELLIGENCE.—Messrs. D. Appleton and Co. will shortly issue new editions of the following works: 1. "The Principles and Practice of Medicine," by Sir William Osler, Bart., M.D., F.R.S. Revised eighth edition. The need for reprinting has given opportunity for considerable revision, notably in the section dealing with infectious diseases. 2. "Preventive Medicine and Hygiene," by Milton J. Rosenau, M.D. New second edition. Amongst the chapters rewritten are those on leprosy, beri-beri, pellagra, and quinine prophylaxis for malaria. 3. "Diseases of Infancy and Childhood," by L. Emmet Holt, M.D., Sc.D., LL.D. New seventh edition. The whole book has been completely revised, with the addition of 16 new chapters and 15 new illustrations. 4. "A Text-book of Bacteriology," by Philip Hanson Hiss, Jr., M.D., and Hans Zinsser, M.D. New third edition.

INFANTILE PARALYSIS IN ABERDEEN.—Dr. Matthew Hay, medical officer of health of the city of Aberdeen, in his monthly report to the Aberdeen town council, states that during the month of September 10 cases of infantile paralysis were reported, making 76 cases in all since the outbreak of the disease up to the end of September. During the present month, October, 3 further cases have been notified, 2 of which, however, took ill in September, and 1 as far back as May. The type of the disease continues mild, only 3 deaths having occurred. All except 2 of the cases for September were in houses of three rooms or under, and with

2 exceptions all the children were under 4 years of age. No contact or association with previous cases was established for any of the cases. Proceeding, Dr. Hay reviews the concurrent, though greatly more severe, epidemic of poliomyelitis in New York, basing his remarks on the weekly bulletins issued by the New York Department of Health. In New York there was only slight evidence of the disease in May, but in June the epidemic was definitely established, the cases multiplying with great rapidity (320 in June, 3731 in July, 4104 in August), and then subsiding quickly from the middle of August. Up to the end of August 1932 deaths occurred, nearly 1 in 4. The type of the disease seems to have been severe from the beginning and to have remained so up to the end of the period for which information is available. In Aberdeen there were also a very few cases in May, and the epidemic was definitely started in June. Referring to the general belief in this country that the percentage of cases among adults was considerable, Dr. Hay divides the cases in New York and in Aberdeen into the following age-groups: (a) cases under 1 year; (b) cases above 1 and under 3 years; (c) cases above 3 and under 5 years; (d) cases above 5 and under 10 years; and (e) cases above 10 years, and finds the following percentage for the two places: Aberdeen, 21, 55, 15, 8, and 1.3; New York, 11, 57, 15, 14, and 2.7. These percentages show the percentage among infants, in proportion to the total cases, somewhat fewer in New York than in Aberdeen, and the cases among persons over 5 years of age somewhat more numerous, but in neither town does it show the proportion of cases among adults to be high.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—A quarterly meeting of the Council was held on Oct. 12th, Sir William Watson Cheyne, the President, being in the chair. Mr. Vincent Warren Low was introduced and made a declaration in the terms of the oath prescribed by the Charter of 1800 and took his seat as a member of the Council. The best thanks of the Council were given to Sir John Bland-Sutton for presenting to the museum a collection of four gorilla skeletons, the skeleton of a chimpanzee, and some skulls. It was resolved that, as recommended by the Library Committee, the library shall be closed at the hour for screening lights. Sir John Bland-Sutton, on behalf of the Committee on the Annual Report of the Council, submitted a draft report to be presented to the Fellows and Members at the annual meeting on Thursday, Nov. 16th. The report was approved and adopted. Sir George H. Makins was re-elected a member of the Committee of Management. The Council nominated as the twenty-fourth Jenks scholar Mr. John Sinclair Shadwell, formerly of Epsom College and now at Guy's Hospital Medical School. A letter was read from Lieutenant-Colonel James W. Barrett, R.A.M.C., F.R.C.S., calling the attention of the Council to the disabilities under which Fellows of the College when resident abroad, laboured as regards taking part in the election of members of Council. A committee was appointed to consider and report as to the possibility of making a long interval between the date of nomination of candidates and the election.

MEDICAL MAYORS IN THE WEST OF ENGLAND.—The Lord Mayor of Bristol (Mr. Barclay J. Baron, M.B., C.M. Edin.), at the unanimous wish of the city council, has consented to be re-nominated for a second term of office.—Alderman H. Gordon Cumming, F.R.C.S. Eng., has accepted the invitation of the Torquay town council to become mayor for the ensuing year.

GIFTS OF THE KHARTOUM CHAPTER.—The Khartoum Chapter of the Daughters of the British Empire in Wilmette, Illinois, U.S.A., has endowed a bed for a year in Roehampton House, one of the Queen Mary Auxiliary Convalescent Hospitals for crippled sailors and soldiers. The bed is known as the "Khartoum Chapter Bed." The chapter has also sent hospital supplies to Beaufort War Hospital, Bristol, and to the Scottish National Red Cross Hospital in Glasgow.

THE WILL OF THE LATE SIR VICTOR HORSLEY.—Probate of the will of the late Sir Victor Horsley has been granted to Lady Horsley, the property being of the value of £35,000. The will directs that within 24 hours of his death a post-mortem examination of his body shall be made by the pathologist of the National Hospital for the Paralyzed and Epileptic, Queen-square, and that his brain and skull should be given to and preserved by the Neurological Society of London, and the remainder of his body to the museum of University College for the preparation of such specimens as the curator may think fit; the pathologist who makes the examination to be paid 10 guineas. The testator gives his professional furniture, books, and instruments to such of his children as may enter the medical profession, and if none of them do, then to the pathological department of University College. All other his property he leaves to his wife for life, with remainder to his children as she may appoint.

THE LATE DR. J. G. MACINDOE.—James Gray Macindoe, M.B., C.M. Edin., late Major, R.A.M.C. (T.F.), died recently at his residence, Torrington, Devon, in his forty-eighth year. The deceased was well known and highly respected, and had an extensive practice. He held several appointments and was medical officer to the workhouse and for two districts of the Torrington union, and also public vaccinator.

ASSISTANT MEDICAL OFFICER OF HEALTH AT PLYMOUTH.—The Plymouth borough council had recently decided to advertise for an assistant medical officer of health, at a commencing salary of £300, increasing by £25 yearly to £400 per annum. The candidate was required to devote the whole of her or his time to the work, which was to be principally in connexion with the maternity and child welfare work of the council. At the last meeting of the council it was stated that the commencing salary offered for the post had to be increased to £350, "because the medical papers refused to accept these advertisements with a less salary."

THE LATE DR. JOHN R. HAMILTON.—Dr. Hamilton, a well-known medical practitioner in the south of Scotland, died on Oct. 7th at his residence, Elm House, Hawick, Roxburghshire, aged 63 years. He graduated M.B., C.M. Edin. in 1875, taking the L.R.C.S. Edin. in the same year, and the M.D. of his University, with commendation, in 1878. He was keenly interested in all that concerned the welfare of his profession and was a member of the council of the British Medical Association, being at one time chairman of the Scottish committee.

THE HARVEIAN ORATION of the Royal College of Physicians of London was delivered on Wednesday afternoon last, Oct. 18th, by Sir Thomas Barlow.

THE GRESHAM LECTURES will be delivered on Tuesday, Wednesday, Thursday, and Friday of next week at Gresham College, Basinghall-street, E.C., by Dr. Harry Campbell.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Parliamentary Session.

PARLIAMENT re-assembled on Tuesday, Oct. 10th. The first duty of the Legislature was to authorise the expenditure of money for the prosecution of the war. For that purpose a further Vote of Credit to the amount of £300,000,000 has been passed by the House of Commons, and at the current rate of expenditure this sum will suffice until Christmas. This brings the aggregate of the Votes of Credit sanctioned since the beginning of the war up to £3,132,000,000. The Prime Minister, in reviewing the military situation, said that this was not a moment for faint hearts, faltering purpose, or wavering counsel. "The ends of the Allies," he continued, "are well known. They have been frequently and precisely stated. They are not selfish ends. They are not vindictive ends, but they require that there shall be adequate reparation for the past and adequate security for the future. On their achievement we in this country honestly believe depend the best hopes of humanity." The House of Commons has been giving its attention almost entirely to questions relating to the war—man-power, volunteers, Army contracts, and food supplies.

Health of Troops in Mesopotamia.

In view of the situation in Mesopotamia earlier in the year, Mr. ASQUITH's few remarks on the present position are worthy of note. He said that the hot weather of the past month had hampered active operations, but substantial progress had been made in the improvement of our rail and river communications. The health of the troops had also greatly improved. General MOORE assumed the command of the forces in Mesopotamia on August 28th, and his most recent reports indicated that real headway was being made in overcoming the difficulties which had hitherto hampered our operations in this theatre.

HOUSE OF COMMONS.

WEDNESDAY, OCT. 11TH.

Sale of Cocaine.

Mr. HOGGE asked the Home Secretary whether he was in a position to state whether he intended to carry out his proposed restrictions on the use of cocaine by unregistered dentists.—Mr. H. SAMUEL answered: The exemption which allows unregistered dental practitioners to purchase solutions containing 0.1 per cent. or more of cocaine has been extended to Oct. 31st. I am satisfied that there is no need to extend

the exemption beyond that date, as other efficient local anaesthetics will be available in sufficient quantities.

Mr. HOGGE: Will the right honourable gentleman apply this restriction also to registered dentists so that the whole supply may be properly controlled?—Mr. H. SAMUEL: I am advised that it is in no way necessary to apply restrictions to registered dentists, because all those dentists are known from the very fact of registration, but any person could call himself an unregistered dentist and could obtain a supply of cocaine if this restriction were not in force.

Mr. HOGGE: Is the right honourable gentleman aware that a large number of what he calls registered dentists, 1600 are not qualified and got on the Register when legislative provisions were made with regard to registration?—Mr. H. SAMUEL: They have a recognised status.

THURSDAY, OCT. 12TH.

Incapacitated Prisoners of War.

Mr. MALCOLM asked the Under Secretary for Foreign Affairs whether the offer of the Danish Government to receive invalid British prisoners of war had been accepted; and whether any such were now interned in Denmark.—Mr. J. HOPE (on behalf of Lord ROBERT CECIL) answered: We have informed the Danish Government that we highly appreciate their generous offer, which has received our most careful consideration. We understand, however, that ample accommodation for prisoners of war is still available in Switzerland, the only difficulty encountered in the operation of the arrangement in force with that country being that of inducing the German Government to agree to the transfer thither of all British officers and men who are entitled to the privilege. In these circumstances we feel that it would be premature to extend the arrangement to other neutral countries at present, but should the accommodation in Switzerland prove insufficient in future, we shall be glad to reconsider the kind offer made to us by the Danish Government.

Replying to a further question, Mr. HOPE said that an agreement had been arrived at with the Bulgarian Government for the exchange of incapacitated prisoners of war.

The Price of Milk.

Answering Mr. BARNES, Mr. RUNCIMAN (President of the Board of Trade) said: I am aware that in certain London districts the price of milk has recently been raised from 5d. to 6d. per quart, the price which has been in vogue in several other districts for several months. The Board of Trade, in conjunction with the Board of Agriculture, have been following the course of milk prices with careful attention. They have also obtained certain data regarding the cost of production and distribution, but as stated, in the report of the Departmental Committee on Prices, it is admittedly a very difficult thing to state accurately the cost of production of a gallon of milk. Several of the recommendations contained in that report deal, however, with the question of milk prices, and immediate action will be taken on those where practicable. With a view to enabling dairy-farmers to meet the strain of work during the winter, the further calling up of their men for military service has been deferred, and it is expected that they will respond by offering their milk on terms which will not involve any further rise in retail prices.

Medical Supplies in Mesopotamia.

Sir JOHN JARDINE asked the Financial Secretary to the War Office whether he was in a position to make a statement about any increase of transport on the River Tigris and between Kurma and Nasiriyah, on the River Euphrates; and whether it was now practicable without unreasonable delay to send on from Basra to the garrisons on those rivers supplies of medicines and hospital appliances and comforts sent for their use.—Mr. FORSTER replied: Yes, sir, since the end of July, when the War Office took over control, there has been a large increase in the river transport available in Mesopotamia. The increase is already 64 per cent., and will shortly be 100 per cent. The whole system has been reorganised, and there is ample transport available to take up promptly all the medical stores required.

Experiments with Chlorine Gas.

Mr. CHANCELLOR asked the Home Secretary whether the 84 experiments reported in the return for 1915 as having been performed for the Medical Research Committee by Dr. M. W. Flack included or were in addition to those performed by him on cats and other animals with chlorine gas; whether these gas experiments were paid for out of National Health Insurance funds; and, if so, whether the Auditor-General's attention was called to the matter and the payments passed by him as a proper use of National Insurance funds.—Mr. C. ROBERTS (representing the National Insurance Commissioners) wrote in reply: The experiments referred to in the question are included in the 84 reported in the return. The gentleman referred to is a member of the staff of the Medical Research Committee established by Regulations made under Section 16 of the National Insurance Act, 1911, and the expenditure of that Committee is made from moneys provided by Parliament

under Subsection (2) (b) of that section. The accounts for the matters in question come before the Controller and Auditor-General, who will make such observations as he thinks fit upon them to the Public Accounts Committee in due course.

TUESDAY, OCT. 17TH.

Dentists in Mesopotamia.

Answering Sir JOHN JARDINE, Mr. LLOYD GEORGE (Secretary for War) said: The force in Mesopotamia has been supplied with all the dentists and dental mechanics for whom it has asked. The Army Council were quite recently informed by cable that no more were required. The distribution of the dentists and dental mechanics sent out is, of course, a matter for the discretion of the local military authorities.

Sanitary Conditions of Knockaloe Camp.

Sir W. BYLES asked the Home Secretary whether he had received complaints of the unhealthy and insanitary condition of the Knockaloe camp, Isle of Man; and whether, in view of the approaching winter, he would see that the huts were weather-tight, that the drinking water was filtered, that the sanitary and sleeping arrangements were adequate, and that food was sold to those who could buy it at cost price.—Mr. H. SAMUEL wrote in reply: Knockaloe camp receives the constant attention of the insular authorities and of the Destitute Aliens Committee on behalf of the Home Office. The sanitary arrangements have recently been the subject of special investigation; a new system of drainage is under construction and its completion is being expedited. Steps are being taken to ensure that the huts will be proof against the winter weather when it comes. The supply of drinking water is excellent and is the same as that used by the officers and the town of Peel. The health records are very good. Food is sold in the canteen at low prices, and any profits derived from the sale are handed over by the camp authorities to prisoners' committees and devoted to the general welfare of the prisoners.

WEDNESDAY, OCT. 18TH.

Typhoid and Paratyphoid Fever amongst Troops.

Answering Mr. CHANCELLOR, Mr. FORSTER (Financial Secretary to the War Office) said: Up to August 25th, 1916, 1501 cases were finally diagnosed as typhoid fever amongst the British troops in France, 903 amongst inoculated men and 508 amongst men not inoculated. There were 166 deaths, 47 of which were amongst the inoculated and 119 amongst uninoculated. To the same date there were 2118 cases of paratyphoid fever, 1968 amongst inoculated men and 150 amongst men who had not been inoculated. There were 29 deaths, 22 of which were amongst the inoculated and 7 amongst the uninoculated.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index). When the application of a Belgian medical man would be considered the advertisers are requested to communicate with the Editor.

BERMONDSEY PARISH.—Medical Officer. Salary £250 per annum.
BIRMINGHAM, LITTLE BROMWICH FEVER HOSPITAL.—Female Assistant Medical Officer. Salary £300 per annum, with board, &c.
BRISTOL ROYAL INFIRMARY.—House Physician. Salary at rate of £120 per annum, with board, &c.
CAMBRIDGESHIRE ASYLUM, Fulbourn, near Cambridge.—Junior Assistant Medical Officer, unmarried. Salary £200 per annum, with board, &c.
CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL.—Second House Surgeon. Salary £150 per annum, with board, &c.
COLCHESTER, ESSEX COUNTY HOSPITAL.—House Surgeon.
DUDLEY, GUEST HOSPITAL.—Senior Resident Medical Officer. Salary £150 per annum, with board, &c. Also Assistant House Surgeon, for six months. Salary £120 per annum, with board, &c.
EVELING HOSPITAL FOR CHILDREN, Southwark, S.E.—House Physician. Salary at rate of £160 per annum, with board, &c.
HÔPITAL FRANÇAIS, 172, Shaftesbury-avenue, W.C.—Surgeon to Throat, Nose, and Ear Department.
HUDDERSFIELD COUNTY BOROUGH EDUCATION AUTHORITY.—Assistant School Medical Officer. Salary £300 per annum.
HULL, CITY AND COUNTY OF KINGSTON-UPON-HULL INFECTIOUS DISEASES HOSPITALS.—Resident Medical Officer. Salary as arranged, with board, &c.
ITALIAN HOSPITAL.—House Surgeon for six months. Salary £80 per annum, with board, &c.
LEICESTER ROYAL INFIRMARY.—Pathologist to Infirmary and Venereal Diseases Section. Salary at rate of £500 per annum. Also Medical Officers in Charge of Clinics and Beds. Salary £200 for Male Officer and £150 for Female Officer. Also Vacancy on Resident Surgical Staff. Salary £250 per annum.
LONDON LOCK HOSPITAL (MALE), Dean-street, Soho, W.—House Surgeon for six months. Salary at rate of £150 per annum.
MANCHESTER, HULME DISPENSARY, Dale-street, Stretford-road.—House Surgeon. Salary £250 per annum, with apartments, &c.
MANCHESTER ROYAL EYE HOSPITAL.—House Surgeon. Salary £120 per annum, with board, &c.
MANCHESTER ROYAL INFIRMARY CONVALESCENT HOSPITAL, Cheadle.—Resident Medical Officer, unmarried. Salary £225 per annum, with board, &c.

NEWCASTLE-UPON-TYNE AND NORTHUMBERLAND SANATORIUM FOR CONSUMPTIVES, Barrasford, North Tyne.—Resident Medical Officer.
 NEWCASTLE-UPON-TYNE, ROYAL VICTORIA INFIRMARY.—Four House Physicians, Four House Surgeons, Accident Room House Surgeon, House Surgeon to Aural and Ophthalmic Departments, House Surgeon to Skin and Gynaecological Departments, and House Surgeon to Out-patient Dressing Department.
 NOTTINGHAM GENERAL HOSPITAL.—Two House Physicians and One Assistant House Surgeon for six months. Salary at rate of £250 per annum each, with board, &c.
 PERTH, COUNTY AND CITY ROYAL INFIRMARY.—House Surgeon. Salary at rate of £200 per annum, with board, &c.
 PLYMOUTH, SOUTH DEVON AND EAST CORNWALL HOSPITAL.—Assistant in X Ray and Finsen Light Department.
 QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.—Assistant Resident Medical Officer for four months. Salary at rate of £50 per annum, with board, &c.
 RHONDDA URBAN DISTRICT COUNCIL.—Temporary Assistant Medical Officer of Health and School Medical Officer. Salary £250 per annum.
 SCOTISH WOMEN'S HOSPITALS, 2, St. Andrew-square, Edinburgh.—Medical Women for Serbian Unit in Russia. Salary at rate of £200 per annum. Also Radiographer (women).
 SHEFFIELD CITY HOSPITALS, INFECTIOUS DISEASES.—Resident Medical Officer at Lodge Moor Hospital.
 SHEFFIELD, ROYAL INFIRMARY.—Two House Surgeons. Salary £100 per annum, with board, &c.
 SOUTH LONDON HOSPITAL FOR WOMEN, 103, South Side, Clapham Common, S.W.—Female House Physician and House Surgeon for six months. Salaries at rate of £100 per annum, with board, &c. Also Temporary Female Assistant Physician to Children's Department.
 WALFALL AND DISTRICT HOSPITAL.—Assistant House Surgeon and Anaesthetist. Salary £150 per annum, with board, &c.

Births, Marriages, and Deaths.

BIRTHS.

DE MOWBRAY.—On Oct. 16th, at Grosvenor House, Southampton, the wife of Ralph M. de Mowbray, F.R.C.S. (temporary Lieutenant, R.A.M.C.), of a son.
 FRANKAU.—On Oct. 13th, at Tenby-mansions, Nottingham-street, W., the wife of Claude H. S. Frankau, F.R.C.S., Major, R.A.M.C., of a son.
 McMULLAN.—On Oct. 11th, at Southsea, the wife of George McMullan, M.B., Blair Lodge, Wallingford, of a daughter.

MARRIAGES.

ASHTON—MORHAM.—On Sept. 23rd, at 17, Mansion House-road, Edinburgh, by the Rev. James Lumsden, B.D., Minister of Tolbooth Parish, temporary Captain Basil Cedric Ashton, R.A.M.C., to Agnes May, youngest daughter of George Morham, Edinburgh.
 HARDY—KITCHIE.—On Sept. 14th, at the Parish Church, Creich, Cupar, Fifeshire, Captain Thomas Lionel Hardy, R.A.M.C., to Elizabeth Clark, youngest daughter of the Rev. John Ritchie, Minister of Creich.
 STEWART—MYLNER.—On Oct. 12th, at Peolali, India, Captain William Stewart, R.A.M.C., to Dorothy Evadne, younger daughter of Ernest Mylner, Esq., of Behea, India, and of Ellenborough House, Roehampton, Surrey.

DEATHS.

FARR.—On Oct. 11th, suddenly, at Earl's Court-road, S.W., Frederick Arthur Farr, M.R.C.S., L.R.C.P., in his 67th year.
 HICKMAN.—On Oct. 16th, at "The Hollies," Wanstead, Herbert Vigers Hickman, M.B. Lond., aged 54.
 LACEY.—On Oct. 11th, died of wounds, Lieutenant William S. Lacey, R.A.M.C., D.E.C.P. Lond., M.R.C.S. Eng., L.D.S. Eng., D.M.D. Harvard, aged 29 years.
 PUZKY.—On Sept. 10th, at Prince's-avenue, West Kirby, Cheshire, suddenly, Chauncy Puzey, F.R.C.S., formerly of Rodney-street, Liverpool.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

BOOKS, ETC., RECEIVED.

HEINEMANN, WILLIAM, London.

Notes, Short Comments, and Answers to Correspondents.

HOSPITALS AND DISPENSARIES IN HONG-KONG.

THE Hon. Claud Severn, Colonial Secretary, in his report on the Blue-book of Hong-Kong for 1915, states that the estimated total population of the Colony, including the New Territories, is now 509,160. During the year 3085 in-patients and 14,499 out-patients were treated at the Civilian Hospital. In the Victoria Hospital for Women and Children at the Peak, 158 patients came under treatment. At the Kennedy Town Infectious Diseases Hospital 5 cases were treated, all being small-pox. At the Tung Wa Hospital, in which only Chinese are treated, there are 323 beds, and 4796 patients were accommodated during 1915, and at the branch hospital for small-pox cases (also Chinese only) 7 patients were admitted. The Alice Memorial and Affiliated Hospitals are managed and controlled by the missionaries resident in Hong-Kong, agents of the London Missionary Society, and consist of the Alice Memorial Hospital (opened in 1887), the Nethersole Hospital (opened in 1895), the Maternity Hospital (opened in 1904), and the Ho Miu Ling Hospital (opened in 1906). The total number of in-patients in 1915 was 1059, and the number of labours in the Maternity Hospital was 428. The new Kwong Wa Hospital for Chinese in the Kowloon Peninsula contains 70 beds, and 1904 patients were accommodated during 1915. One of the most important institutions in the colony not supported by Government funds is the Matilda Hospital, which stands on a commanding site of nearly three acres at Mount Kellet in the Hill District. It consists of a main building containing six wards with 26 beds, quarters for four nurses, a house for the medical officer in charge, and an operation block. A maternity ward, connected by a covered way, is in course of erection. The total cost of the buildings and their equipment has been more than \$600,000. The hospital was erected in pursuance of the directions of the late Mr. Granville Sharp, who died in 1899, and who by his will left upwards of \$2,000,000 in trust "for the erection and maintenance of a hospital at Mount Kellet to the glory of God and the good of men, in loving memory of his sainted wife, Matilda Lineolne." The objects of the testator are thus defined: "(a) To provide, carry on, and maintain a hospital for the benefit of patients primarily who are poor, helpless, and forsaken, and to provide gratuitous medical relief to any such persons suffering from disease or ill-health. (b) The hospital shall be considered to be established as a religious and evangelistic institution. (c) The hospital is reserved for British, American, and European patients."

Nine Chinese public dispensaries are maintained by voluntary subscriptions to provide the Chinese with the services of doctors whose certificates will be accepted by the registrar of deaths, and with the services of interpreters who can assist the inmates of houses where cases of infectious disease have occurred. Coolies are engaged and ambulances and closed vans provided in order to remove cases of infectious disease to the infectious diseases hospital and dead bodies to the mortuary. The dispensaries receive sick infants and send them to one or other of the convents, and arrange for the burial of dead infants. Free advice and medicine are given and patients are attended at their houses.

BENTLEY AND TRIMEN'S "MEDICINAL PLANTS."

To the Editor of THE LANCET.

SIR,—In the British Pharmacopœia, 1898, the medicinal plants are frequently referred to: Bent. and Trim. Med. Pl., Vol. —, Plate —. Please give me full names of the authors and where I might be able to get a complete copy.

I am, Sir, yours faithfully,

Tasmania, August 21st, 1916. J. L. KERR, M.D.

* * The abbreviations refer to the following work: Bentley (Robert) and Trimen (Henry). Medicinal Plants; being descriptions with original figures of the principal plants employed in medicine, and an account of their properties and uses. Parts 1-42 in 4 vols. 8vo. London: J. and A. Churchill. (1875-1880.) It was illustrated with coloured plates by D. Blair, and has been out of print for some years. It was sold at £11 11s.—ED. L.

SIMPLE FIRE PRECAUTIONS FOR THE BLIND.

THE British Fire Prevention Committee has just issued a poster, measuring 20 by 12 inches, with instructions to the blind in Braille what precautions to take in the event of a fire and how to prevent a fire occurring. The latter section includes references to smoking, the use of matches, celluloid, and flannelette. At the head of the poster the instructions are printed in ordinary type, with the heading

"Warning. Simple Fire Precautions for the Blind." In the Braille the word "simple" is not repeated. The omission may be intentional. Precautions are doubtless not so simple for the blind as to those who see. The notices are suitable for fixing on walls as posters, but in that case they must, of course, be placed within reach of the fingers of the blind. The total number of blind folk in the British Isles is estimated at between 30,000 and 40,000, and there are many schools, homes, workshops, and institutions for their benefit in which these posters would be of service. The committee has decided to provide the warning after receiving information from various quarters that nothing so far had been done for the blind in this regard. Their enterprise is commendable. The official title of the poster is "Free issue for the Blind, No. 29." It is to be obtained from the General Honorary Secretary, Mr. Ellis Marsland, 8, Waterloo-place, Pall Mall, London, S.W.

THE PROLIFICITY OF OPPOSITE TWINS.

To the Editor of THE LANCET.

SIR,—There is a popular and apparently widely known belief that in the case of twins of opposite sexes the girl is invariably sterile, and I should be grateful to any of your readers who can adduce evidence in disproof of this.

I am, Sir, yours faithfully,

Oct. 13th, 1916.

H. S. S.

"We have never heard of this as a supposition. As a fact, we know a lady who has a twin brother, 14 children, and 19 grandchildren.—ED. L.

SPHAGNUM MOSS.

A STRONG appeal has been issued by the authorities of the Auxiliary Hospital, Southernhay, Exeter, for sphagnum moss. It is stated that large quantities are required, and it is advised that this should be sent in before the winter rains make it difficult to gather. The secretaries, Bedford-buildings, Tavistock, Devon, add that it is the duty of every person residing near areas where sphagnum moss grows to send a liberal supply to the hospitals, and assistance is also required from people to clean and dry the moss.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Wednesday, Oct. 25th.

HISTORY OF MEDICINE (Hon. Secretaries—J. D. Rolleston, Charles Singer): at 5 P.M.

Presidential Address:

Dr. Raymond Crawford: Legends and Lore of the genesis of the Healing Art.

Thursday, Oct. 26th.

NEUROLOGY (Hon. Secretaries—H. Campbell Thomson, C. M. Hinds Howell): at 8.30 P.M.

Presidential Address:

Prof. W. D. Halliburton, F.R.S.: The Possible Functions of the Cerebro-Spinal Fluid.

Friday, Oct. 27th.

STUDY OF DISEASE IN CHILDREN (Hon. Secretaries—A. S. Blundell Bankart, E. A. Cockayne, C. P. Lapage): at 4.30 P.M.

Cases:

- Dr. F. Parkes Weber: Case of Cerebral Diplegia with Excessive Mobility (Atony) of Joints.
- Dr. F. Langmead: A Family showing Cleido-cranio-dysostosis.
- Dr. C. E. Lakin: Case of Intra-thoracic Neoplasm.
- Dr. E. A. Cockayne: (1) Juvenile G.P.I. with Hypo-pituitarism; (2) Werdnig-Hoffmann Type of Progressive Muscular Atrophy.

EPIDEMIOLOGY AND STATE MEDICINE (Hon. Secretaries—William Butler, Major Greenwood, jun.): at 8.30 P.M.

Paper:

Capt. C. G. Moor: Work of a Sanitary Section at a Base.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—8.30 P.M., Mr. D. McC. Altken: Demonstration of Cases illustrating Orthopedic Principles and Methods in Military Surgery.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simson: Diseases of Women.

TUESDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Dr. Simson: Diseases of Women.

THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Simson: Gynaecological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10.30 A.M., Surgical Out-patients (Mr. E. Gillespie). 2.30 P.M., Medical Out-patients (Dr. T. R. Whipple); Gynaecological Out-patients (Dr. Banister). 3 P.M., Medical In-patients (Dr. R. M. Leslie).

TUESDAY.—2.30 P.M., Surgical Operations (Mr. Carson). Clinics:—Medical Out-patients (Dr. A. G. Auld); Surgical Out-patients (Mr. Howell Evans); Nose, Throat, and Ear Out-patients (Mr. C. H. Hayton). Radiography (Dr. Metcalfe). 3.30 P.M., Medical In-patients (Dr. A. J. Whitting).

WEDNESDAY.—Clinics:—2.30 P.M., Throat Operations (Mr. C. H. Hayton). Children Out-patients (Dr. T. R. Whipple); Eye Out-patients (Mr. R. P. Brooks); Skin Out-patients (Dr. H. W. Barber). 5.30 P.M., Eye Operations (Mr. R. P. Brooks).

THURSDAY.—2.30 P.M., Gynaecological Operations (Dr. A. E. Gilles). Clinics:—Medical Out-patients (Dr. A. J. Whitting); Surgical Out-patients (Mr. Carson); Radiography (Dr. Metcalfe). 3 P.M., Medical In-patients (Dr. R. M. Leslie).

FRIDAY.—2.30 P.M., Surgical Operations (Mr. Howell Evans). Clinics:—Medical Out-patients (Dr. A. G. Auld); Surgical Out-patients (Mr. E. Gillespie); Eye Out-patients (Mr. R. P. Brooks).

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C.

TUESDAY.—4 P.M., Dr. C. Kempster: X Rays. The Tube and its Control.

THURSDAY.—6 P.M., Chesterfield Lecture:—Dr. M. Dockrell: Anomalies of Pigmentation and what they Indicate.

THE THROAT HOSPITAL, Golden-square, W.

MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.

THURSDAY.—5.15 P.M., Clinical Lecture.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

Offices: 423, STRAND, LONDON, W.C.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsgagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

Subscribers abroad are particularly requested to note the rates of subscriptions given on page 4.

The Manager will be pleased to forward copies direct from

The Harveian Oration.

*Delivered at the Royal College of Physicians of London on
Oct. 18th, 1916.*

By SIR THOMAS BARLOW, Bt., K.C.V.O.,
M.D., F.R.S.,

FELLOW OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

HARVEY, THE MAN AND THE PHYSICIAN.

MR. PRESIDENT, FELLOWS OF THE COLLEGE, AND GENTLEMEN.—Once again we meet on St. Luke's Day to commemorate the benefactors of our beloved College and to carry out the injunctions of the illustrious Harvey, who was the greatest benefactor of them all.

COMMEMORATION OF BENEFACTORS.

As in duty bound, we recall to grateful remembrance the name of Linacre, our first President. He was the real founder of the College, for it was largely through his enlightened counsel that Henry VIII. was induced to confer the Charter. He was not only a pioneer in the revival of learning in this country, but he was a physician in the highest sense; he laid the foundations of the College on broad and noble lines, and, Churchman though he was, he kept it free from any ecclesiastical domination. The early meetings were held in his house in Knight-riding-street, and it seems clear that during his lifetime he presented his house to the College.

The services of John Caius to the College of Physicians come only second to his benefactions to Gonville and Caius College, Cambridge. He was elected President no less than nine times, and the "Annals" written with his own hand from 1555 to 1572 were not only invaluable as records, but helped to make and maintain the College tradition. The caduceus, which is one of the insignia of the President's office, was his gift. We commemorate Caius not only as a great scholar, but as the first teacher of anatomy in England, as a naturalist, and as one of the early writers on clinical medicine, as evidenced in his careful study of the sweating sickness.

Richard Caldwell, who was our President in 1570, must be always gratefully remembered for his endowment jointly with Lord Lumley of the Lumleian lectureship.

William Gilbert, the pioneer in the study of magnetism, justly designated the father of experimental philosophy in England and the inspirer of Galileo, was our President in 1630 and bequeathed to us his library, globes, instruments, and mineral collection.

Then comes Harvey, and I will limit myself for the present to the enumeration of his material benefactions. In 1651, when he was 73 and living in retirement, though still Lumleian lecturer, he offered to build and present to the College, then situate at Amen Corner, a library and museum. In two years' time these additions to the edifice along with a great parlour or conversation room in which the fellows could meet, were duly presented and conveyed during the presidency of Dr. Prujean. In 1656, when he resigned the Lumleian lectureship and said good-bye to the fellows, he gave his patrimonial estate at Burmarsh, on the Kentish coast near Dymchurch, to the College. The value of this estate was at that time £56 a year, and Harvey's desire was that an annual feast should be held, that an oration in commemoration of benefactors should be given, that a fee should be given to the orator, and a salary to the keeper of the library and museum, which he had already founded and furnished. Finally, in his will, having taken the precaution of securing that if any part of the building which he had already given were not completed money from his estate should be provided for its completion, he devised books and papers and his best Persia long carpet and his blue satin embroidered cushion and a pair of brass andirons, with fire shovel and tongs, for the ornament of the meeting-room which he had erected. The record of these simple gifts is precious, because it shows that the solicitude of Harvey was not only for the advancement of medical learning but for the promotion of the amenities of the College and that the meeting room should be as far as possible like a home to the fellows.

No. 4861.

Theodore Goulston, who was one of Harvey's younger contemporaries and was Censor for a time, left an endowment for a lectureship to be given to one of the four youngest fellows of the College.

Sir Theodore de Mayerne, who was another of Harvey's contemporaries, was like his fellow countryman Casaubon, an example of the fundamental tolerance and broadmindedness of the English nation. After a distinguished medical career in France he was hospitably received in this country and rose to be Court physician to James I. and Charles I. He became a fellow of our College, gained a high reputation, and bequeathed his library when he died.

We next come to Baldwin Hamey, junior. He was another of Harvey's contemporaries and, indeed, one of his most intimate friends. He was our treasurer from 1664 to 1666 and gave anatomical lectures to the College. Though a strong Royalist he had a lucrative *chénille* amongst the leading men of the Commonwealth and was our most munificent benefactor. The local habitation of this College in 1651 was Amen Court on land belonging to St. Paul's. The security of tenure was in grave peril from threatened levies on church property. With splendid foresight Hamey brought the property and presented it to the College free of all encumbrances. After the fire of 1666 the College was rebuilt in Warwick-lane and Hamey contributed to the cost of rebuilding. He decorated the Cœnaculum with rich woodwork of Spanish oak and some of this beautiful wainscoting was utilised for our Censors' room when the College was removed to its present site. Finally, Hamey followed his friend Harvey's example by settling in 1672 the estate of Ashlins at Great Osgar in Essex upon the College. There was a gracious personal note in Hamey's last gift, in that over and above a contribution to general purposes he allotted part of the annual income which would accrue to be devoted to the augmentation of Harvey's special benefactions.

The Marquis of Dorchester was one of our few honorary fellows and may also be considered to belong to Harvey's circle. He had been a devoted student of physic and anatomy and had probably gained Harvey's regard in Oxford. At all events Harvey was one of his sponsors when he was elected. He greatly enriched our library.

Dr. Croone was Censor in 1679 and was one of the original fellows of the Royal Society, of which for a time he was secretary. To him we owe our most valuable endowments. He had intended to found two lectureships, one at the College and the other at the Royal Society, and his beneficent intention was carried through by his widow, who subsequently became Lady Sadleir.

I have further to enumerate the Bradshaw, the Milroy, the FitzPatrick, the Oliver Sharpey, and the Dobell lectureships, the Murchison and Jenks scholarships, the Baly, Moxon, and Hawkins medals, the Swiney prize, and the Weber-Parkes prize and medals for the encouragement of the study of tuberculosis by Sir Hermann Weber, the Nestor of our fellows, still, I rejoice to say, in our midst, beloved and honoured by us all.

By your permission, Mr. President, I have to announce that in June last Mrs. Eliza Streatfeild, of 22, Park-street, Mayfair, acting upon the advice of our friend, Sir John Tweedy, offered a sum of money to the two Royal Colleges for the purpose of endowment of research. The offer was gratefully accepted, and the deed approved by this College at the last quarterly Comitia provides for the transfer of £10,000 $2\frac{1}{2}$ per cent. annuities into the joint names of the two Colleges as trustees to be known as the Streatfeild Research Fund, the interest to be applied to the promotion of research in medicine and surgery.

HARVEY'S EARLY STUDIES.

And now let us return to Harvey himself, the greatest of our benefactors. For we measure our indebtedness, not alone by the munificence of gifts in their money value, but by the additions made to the science and art of medicine, by the examples of devotion to the highest aims of life, and by the proofs of attachment to the best medical interests of the body politic which this College has endeavoured to safeguard and to represent. Weighed in these balances none will deny Harvey's supremacy.

I shall not trespass on your good nature by recounting in detail the oft-told tale of Harvey's life and great discovery. It may well be said that there is nothing more to be obtained

from a quarry that has been so often and so assiduously worked. If some of the points to which I ask your attention may seem of minor importance in themselves I may claim the excuse that everything which throws even a fresh glimmer on Harvey's life and character is at least worthy of consideration. We know that the young Harvey was a pupil at the King's School, Canterbury, from the age of 10 to 15, where we may well assume that he gained the foundations of that classical knowledge which stood him in such good stead throughout his life. It was there probably that he made his first acquaintance with Virgil, whose poetry fascinated him in his later life; is it possible that he may even have begun to read Aristotle, whose influence over him was greater than that of any other writer, ancient or modern?

But were there no other studies than the classics which laid hold of young Harvey in his schoolboy days? Dr. Venn, the learned President of Caius College, Cambridge, has drawn my attention to the regulations of the scholarship which Harvey obtained and which enabled him to go from King's School, Canterbury, to Caius College for six years. The scholarship was founded in 1571 by Matthew Parker, Archbishop of Canterbury, who was an intimate friend of Dr. Caius, and it is not unlikely that Caius influenced Parker in framing the conditions under which it was given. The most interesting of these is the enactment that at the University the scholar shall be educated first in subjects that pertain to or are serviceable to medicine and then in subjects which actually constitute medicine itself.

Such a regulation for a medical scholarship is very remarkable and Dr. Venn considers unique at that time. But let us consider for a moment its bearing upon Harvey and his predilections. It is not unreasonable to assume that he had already determined to become a doctor. Are we justified in any further speculations? We know that throughout his later life Harvey was not only devoted to comparative anatomy but that he was a keen naturalist. In Harvey's *Prelectiones* Dr. Norman Moore points out that there are references to the anatomy of no less than 80 animals. His book on generation is a perfect mine of observations on natural history. In his continental travel with the Duke of Lennox he complains bitterly that there was scarcely a dog, crow, kite, raven, or any bird or anything to anatomise; and when he was travelling with Lord Arundel in Germany, on the testimony of Hollar the artist, he made frequent excursions in the woods making observations on strange trees, plants, earths, and "naturalis," and caused some anxiety to Lord Arundel lest he should be waylaid or murdered.

This intense lifelong devotion to natural history is usually an inborn quality, and it is by no means unlikely that in Harvey's schoolboy days it was this strong predilection that justified the authorities in nominating him to what was practically a medical scholarship.

Harvey at Cambridge.

Harvey's first term at Cambridge began in May, 1593, when, we are told, he was admitted to the scholars' table at Caius College. Dr. Caius had been gathered to his fathers 20 years before. Dr. Legge, whom he had appointed as his successor, was of Caius' way of thinking in his Roman proclivities, and there was a stormy time in the College for awhile. There is no indication that Harvey was drawn into this conflict, and it may have quieted down when he entered the College. His tutor and surety was George Estey, who seems to have been a worthy parson and was appointed Hebrew lecturer the year after Harvey's entrance, but Harvey never refers to him.

Although Caius College had a medical reputation, we find rather meagre evidence of systematic instruction in medical subjects, and this in spite of Dr. Caius having laid down certain definite plans for its maintenance. He had obtained a licence for the dissection of two bodies annually in the winter and for their decent burial. The church registers give evidence that bodies, chiefly of prisoners, were dissected. Demonstrations were given.

Dr. Venn, by reference to the *Exiit Book* and the *Computus Book* of the College, which give detailed entries of the students' absences and the charges for their commons, has furnished me with some interesting and suggestive information about Harvey's time at Cambridge. As these entries have an important bearing on the question of when Harvey left Cambridge and when he entered Padua, I bespeak your

consideration of them. It is commonly stated that Harvey took his B.A. degree in 1597 and that he left Cambridge in 1598 and entered Padua in that same year. I think you will see that that is incorrect. He entered Padua in 1600.

The *Exiit Book*, which was made up half-yearly, shows that during the first three years there were no absences. This may mean that Harvey did not leave the College at all during this period or for such brief intervals as did not involve any deduction from the stipend of his scholarship. We have to remember that one month's absence for holiday was allowed by statute, and that could be taken at any time. The *Computus*, or account book, is consistent, for it shows that Harvey's stipend from his scholarship was very nearly sufficient to pay the cost of his commons. But from 1596 to 1599 the *Exiit Book* shows repeated absences.

It is clear, then, that from those dates Harvey was away from College not less than sixteen months. Some of his absences were of two months' duration or more, and some of them a few days up to a fortnight, and from his own letter in Michaelmas, 1599, he evidently required at times a long period for convalescence. The accounts show that he only received a stipend for one quarter between Michaelmas, 1599, and Lady Day, 1600—so that his scholarship lapsed at Christmas, 1599. We know that, like Sydenham, Harvey suffered at various times severely from gout. He complained very little of his ailments and somewhere speaks of the help which his pathological and anatomical investigations gave him by rousing his keen interest and making him forget his pains. I suggest that the absences during the last half of Harvey's time at Cambridge were probably due to attacks of gout.

Harvey took his Arts degree in 1597, but there are no details obtainable concerning it, nor about his work at Cambridge after he had taken his degree. It is significant that there are no references in Harvey's works to his Cambridge life. His poor health and the limited facilities for anatomical study may have left this period as one which he would gladly pass by.

There is a categorical statement in Aubrey's memoirs that Harvey bequeathed the house in which he was born in Folkestone to Caius College, Cambridge, in spite of the protest of his brother Eliab. This has been quoted again and again, but, like many of Aubrey's statements, it is untrue. Harvey bequeathed nothing to Caius College.

Entry at Padua University.

We may take it, then, that following in the footsteps of Linacre and Caius and of other fellows of this College, Harvey went in the year 1600 to Padua and not in 1598. Now it is interesting to mention that an examination of the archives of Padua, made by the University authorities at Mr. D'Arcy Power's request, has failed to reveal any mention of Harvey before 1600. To quote from Mr. Power's admirable life of Harvey, there are entries which show that at the usual time of election—that is to say, on August 1st in the years 1600, 1601, and 1602—he was elected a member of the Council of the English nation in the Jurist University of Padua. This I take to have been a sort of students' association.

Those of you who have been to Padua will remember in the University courtyard the host of memorial tablets giving the arms and name and the nationality of centuries of alumni. Two in the lower cloister are alleged to pertain to Harvey. One of them is decayed and the inscription erased, but the other is well preserved, is undoubted, and gives 1600 as the date. This agrees with the data which I have given already.

The two most interesting things at the University of Padua are the great cathedra or wooden pulpit from which Galileo addressed his class in Harvey's time, and the anatomical theatre where Fabricius demonstrated his dissections to Harvey and his fellow-students. They are not far apart. There is a capital picture of the anatomical theatre in the charming book on Harvey written by Dr. Curtis of Columbia University and published last year. Dr. Curtis points out that the tiers are really standing-places with rails in front to lean upon, which arise at a very steep angle from the central pit. The arrangement now in vogue, in fact, more resembles that in our hospitals in which students stand and look down at the operations or at post-mortem demonstrations than an ordinary anatomical lecture theatre. Dr. Curtis makes the suggestive remark that "the place looks fit to have been a nursery of object teachers, for it is too small to hold a

pompous cathedra, and the veteran to whose Latin the young Englishman listened must have stood directly beside the dead body."

INTELLECTUAL ATMOSPHERE OF EUROPE IN 1600.

And now, before we follow Harvey's further career, let us pause for a moment to consider the intellectual atmosphere of Europe when he began his course at Padua. There had been the great revival of classical learning, followed not only by the Reformation and the consolidation of the Protestant States, but by the counter Reformation in the old Catholic countries. And there was a great ferment of free inquiry on philosophy, on the principles of government, on the polity of nations, the rights of the humbler folk and the conduct of life. The creation and the dissemination also of our greatest literature was then in progress in our own country.

England in spite of its insularity always, I believe, the most tolerant and open-minded of European countries, welcomed to permanent posts many learned men from other lands. Continental travel attracted many of our countrymen, and English scholars sought illumination in those days far more in Italy than in Germany or even in France.

It concerns us most of all to ask what branch of natural science chiefly attracted educated men. I have already referred to our president, William Gilbert, and his influence on Galileo. Galileo had been lecturing six years at Padua before Harvey went there. But we must bear in mind that though he had many ardent disciples both in Padua and Florence, yet he had to encounter formidable opposition as well as persecution, and both his discoveries and his doctrines were a long time in gaining acceptance. Harvey himself seems always somewhat timid about the findings of astronomy, and regards them as unprovable. Astrology was still widely accepted. Robert Boyle was not born till 1627 and the work of Torricelli and of Pascal was yet to come. The Royal Society held a few informal meetings in 1645, but did not receive its charter till 1662.

Thus, although at the end of Harvey's life physics had made great advances, at the time of which we now speak—viz., 1600—it was by no means a popular science. The chemistry of that time was dominated by unverifiable hypotheses, and it is quite what we should have expected that Harvey, according to Aubrey's statement, undervalued its exponents and spoke against it; it was much too vague and nebulous to suit Harvey.

We have, then, to turn from the physical to the biological sciences. The subject which not only engaged the energies of some of the greatest men of that generation, but also attracted extensively the interest of educated people, was human anatomy. Italy was the Mecca of anatomical students. At Padua itself there was a great tradition, for Vesalius, Fallopius, and Fabricius formed a brilliant succession of teachers. Dr. Caius, as we know, had not only studied with Vesalius, but had lived in the same house with him.

The Study of Human Anatomy.

But with regard to human anatomy as a subject of interest amongst educated people, let me read you a sentence or two from Evelyn's Diary, though they relate to a time a little later than this particular date. During the troublous years immediately preceding the Commonwealth, Evelyn travelled on the continent. Whilst at Padua he took out a short course of anatomy and physic. During a month he tells us that he saw a man, a woman, and a child dissected by Veslingius, the anatomical professor, with all the manual operations of the surgeon on the human body. He also purchased from Veslingius's assistant some rare tables of veins and nerves, and gave orders for a third to be prepared of the lungs, liver, and nervi sexti par and the gastric veins, which he sent to England and ultimately presented to the Royal Society. But before that presentation was actually made we find that Sir Charles Scarborough, who succeeded Harvey as Lumleian lecturer, induced Evelyn to lend them for a time to our College for his own lectures. Scarborough had been unable to induce Evelyn to present them to our College. They were given by the Royal Society to the British Museum and by the British Museum to the Hunterian Collection, and are now in the Royal College of Surgeons Museum. These tables are similar to those six preparations which were given to this College in 1823 by the Earl of Winchelsea. They were said to have been inherited from Harvey and to

have been used by Harvey at his lectures. That, I think, is more than doubtful.¹

Thomas Hobbes, the philosopher, dissected in Paris along with his friend the many-sided physician William Petty, and at a later period Robert Boyle also dissected in Ireland under the same friendly guidance. Descartes studied human anatomy, dissected many brains, and repeated Harvey's experiments on the circulation for himself. The Port Royalists, following Descartes' lead, repeated many vivisection experiments on the circulation.

Fra Paolo Sarpi, the ecclesiastical statesman and adviser of the Venetian Republic, seems to have found time and opportunity to study anatomy to considerable purpose and even to make observations on the valves in veins. He was probably in touch with Fabricius, and we know that Padua partly depended on Venice for some of its anatomical material. Charles I. took the greatest interest in anatomy and in the numerous demonstrations, not only on the circulation of the blood, but on embryology, which Harvey gave him from time to time.

But it is important to note that although the great Italian anatomists had made enormous strides in the study of structure, their knowledge of function was lamentably small—in other words, physiology had not kept pace with anatomy. It has, indeed, been affirmed that physiology had not advanced since the time of Galen, and doubtless its inadequate progress was partly the consequence of the prevailing ignorance of physics and chemistry. But in the evolution of knowledge and of method the disproportionate study of human anatomy on its structural side must be credited with the development of observation, and so far it was a big step in the long and bitter struggle against the trammels of authority.

HARVEY AS PUPIL OF FABRICIUS.

That was the beginning of a momentous epoch in the history of human knowledge when on St. Luke's Day, 1600, a young Englishman, aged 22 years, rather under the average height, with raven hair, dark piercing eyes, rather sallow complexion, and with a keen, restless demeanour and rapid speech, enrolled himself amongst the pupils of the learned, laborious, and generous Fabricius. What was Harvey's exact attainment at this time in the details of anatomy and the technique of dissection we have no means of knowing. But we have reason to believe that even then he was by no means ill equipped with ancient learning; we know that he was a keen and accurate observer and an enthusiastic naturalist, and that he had a mind reflective as to the causes and relations of things, fertile in recognising resemblances and above all ready in making working hypotheses and in devising experiments which would more or less verify those hypotheses. It was in these latter qualities that Harvey's supremacy over his teachers and predecessors ultimately became so manifest. The addition of experiment to observation was vital and far-reaching. The exact relationship between teacher and pupil we do not know, but it must have been very intimate, as proved by all Harvey's references to Fabricius, not only in respect to the organs of circulation but also in respect to his observations and speculations on generation. These references are not merely respectful but reverent.

From the time when Vesalius described the valves of the heart the Italian anatomists had been keenly exercised on the valves in various parts of the vascular system, and Fabricius's discovery of the valves of the veins was as far back as 1574. But the scientific use of the imagination seems to have been dormant with these clever observers, and they were singularly inept in explaining the mechanism of the valves. Sir William Osler suggests that it was reflection on the mechanism of the valves of the veins which, at this early period of his career, set Harvey on the right tack in his great discovery, and there is a remark of Harvey's friend, Robert Boyle, which is not inconsistent with that suggestion. Boyle says that Harvey's observations on "contrivances similar to the valves, used in hydraulic engines for preventing counter-currents, led to his

¹ I suggest for consideration whether these tables may have come into the Winchelsea family not through Harvey but possibly through Sir John Finch (the son of Sir Heneage Finch), who was M.D. of Padua, and not only English Consul there, but Syndic of the University. He was admitted an extraordinary fellow of our College in 1660, and seems to have had for an anatomical pupil one Marchetti, who made "tables of veins, nerves and arteries five times more exact than are described in any author." Vide Dr. Edward Browne's letter to Sir Thomas Browne. Sir Thomas Browne's Works, vol. i., p. 91.

discovery of the circulation of the blood." Whether Boyle's remark refers to the period of study at Padua or not it is certain from the terms of his diploma in our possession that Harvey enormously impressed his teachers and examiners with his knowledge and ability.

HARVEY AS PHYSICIAN.

Harvey returned home in 1602 and after his incorporation as Doctor of Medicine at Cambridge he came to our College and submitted himself to examination as a "candidate," which title in those days I take to have been equivalent to our present designation of member. Dr. Norman Moore has found by consulting the "Annals" that Harvey was examined no less than four separate times between May, 1603, and August 4th, 1604, although he satisfied his examiners on each occasion. Moreover, of his contemporary candidates he was the last to be elected to the fellowship—viz., on May 16th, 1607—he being then 29. Whether in that early period of his connexion with this College he had any opponents we have no other means of ascertaining, but he seems to have had the support of the President, Dr. Atkins, when he applied for the post equivalent to what we should now call assistant physician at St. Bartholomew's Hospital, and especially that of Dr. Wilkinson, whom he assisted and after his death succeeded.

In the literature about Harvey there is nothing more interesting than Sir James Paget's Records drawn from the Annals of St. Bartholomew's Hospital. The relations between the Governors and Harvey are altogether honourable and creditable to both sides. I will only refer to the revised hospital regulations which were submitted by Harvey in 1633 and adopted. These rules show that in general medical policy Harvey was a strong conservative, and that he stoutly maintained the then existing supremacy of physicians over surgeons. The surgeon was not only obliged to consult the physician in all difficult cases and whenever inward physic was required, but he was not to be allowed to perform any major operation without the approbation and the direction of the physician. The surgeon was not only forbidden to give inward physic, but was required to declare to the physician what external remedies he applied in any given case. The surgeon had to attend the physician in his weekly consultations in the great hall to which the patients were brought, and where both matron and apothecary attended. In those days the surgeons had to visit their patients in the wards, and the physician, as a rule, only went to the wards when his patients could not be brought to the hall where most of the medical work was done.

During the 36 years, with certain intervals, that Harvey was connected with St. Bartholomew's Hospital he must have seen a great deal of disease amongst the London poor. But his post of Court physician, first to James I. and subsequently to Charles I., led to his having a considerable *clientèle* amongst the well-to-do. We know that some of the most eminent men of the time were his patients. Aubrey disparages his "therapeutic way," and maintains that although he was a great anatomist he was not much of a physician, and that after his great discovery was fully announced his practice waned.

Aubrey is a very inaccurate person, but this statement may have some truth in it. It is interesting to realise that the philistine is the same in every generation in his estimates of the merits of medical practitioners as in other estimates. If a doctor proves his greatness by some purely scientific discovery which has no immediate practical application, if he distinguishes himself in literature or art, the philistine shrugs his shoulders and says that is all very well, but that such a man should be a good practitioner is impossible. Let us, then, consider some of the evidences derived from Harvey's writings bearing on the subject of his clinical experience.

Clinical Illustrations from Harvey's Writings.

In his first disquisition to Riolanus Harvey refers to his unpublished MS. on Medical Anatomy or Anatomy in its relation to Medicine. This MS., then in Harvey's possession, has, alas! been lost, but it may yet be found. But his own references to this MS. are very relevant to our inquiry. In alluding to its contents Harvey says he—

desires to relate from the many dissections of the bodies of persons diseased, worn out by serious and strange affections, how and in what way the internal organs were

changed in their situation, size, structure, figure, consistency and other sensible qualities from their natural forms and appearances and in what various and remarkable ways they were affected.

I quote this long sentence because it embodies Harvey's ideal of the morbid anatomist and shows that he belonged to the true faith—viz., that the best physicians are first of all good morbid anatomists.

In this letter his illustrations are, as might be expected, chiefly drawn from the diseases of the circulatory system; he gives interesting references to aneurysms, apoplexies, and calcified arteries. In more than one place he refers to the small radial pulse on the distal side of an aneurysm of the neck. He recognised that empyema might ulcerate into the lungs and discharge through the bronchi.

In his work on generation, which contains many clinical illustrations, there is a careful analytical description of the case of Lord Montgomery's son, who had an exposed heart left bare after a severe suppurating injury to the chest, and his report of the post-mortem examination of Thomas Parr is a sample of the thorough way in which he made his autopsies.

In his second letter to Riolanus he shows how wide was his acquaintance with local disturbances of circulation which he had discussed at length in the lost Medical Observations. There was one disease which was common in his contemporaries and of which he had abundant experience in his own person—viz., gout. Whether he was permanently crippled is, I think, doubtful, but that he suffered severe pain, especially in his lower limbs, is quite certain. Heberden sneers at the methods which Harvey adopted to relieve what we may probably regard as attacks of localised gouty hyperæmia. But Harvey's plan of plunging his feet into a pail of cold water seems to have been justified by the results, and Heberden has the candour to admit that he lived till 80, and does not appear to have died from gout but from old age. This mode of treatment shows not only Harvey's courage, but his independence of conventional dogmas. In our own times we have learnt that the local application of cold in febrile and hyperæmic states is not the dangerous thing it was once supposed to be.

In Harvey's *Prelectiones* there are many clinical observations introduced by way of illustration. In his valuable introduction Dr. Norman Moore points out that Harvey was "familiar with scarlatinal desquamation; he had noted the enlarged liver in those who died after long suppuration and the shrunken liver in cirrhosis. The varying appearances of gall-stones and the common shape of large renal calculi were well known to him, and he describes pericarditis and its symptoms from his own observation."

It is quite true that Harvey says very little about drugs in any of his memoirs. That is not exceptional in physicians who are distinguished as morbid anatomists. One would like to believe that when the apothecaries of the time disparaged his "bills" (as prescriptions were then called), they may have been too short and too simple to please the apothecaries. There is a nice report on the case of Prince Maurice when Harvey was with the King at Oxford, in which it is stated about Harvey and his colleague Edmund Smith that the "doctors doe resolve to give very little physic, only a regular dyett and cordyall antidotes." It is significantly added that Prince Maurice did well.

But I think I have noticed occasionally that when a morbid anatomist ventures into the realm of therapeutics he may show an immense confidence in some particular preparation, and it is not altogether an exceptional incident that in a letter to his friend Hamey which we possess, concerning the ailment of a poor woman in whom they were both interested, Harvey extolled the therapeutic value of the heel-bone of the deer. Perhaps he had found it a useful way of administering phosphate of lime. But whether he gave many drugs or few, Harvey had confidence in the relief or removal of pain by "the detraction of blood, the application of cupping glasses, or the compression of an artery which leads to a part." He also used cupping glasses for the relief of asthma.

In his work on generation Harvey shows practical acquaintance with both midwifery and gynecology. He recognised the dangers of retained secretions in the body of the uterus, and showed courage and decision in dilating the cervix and in some cases in the employment of intra-uterine injections. He had carefully studied cancer of the uterus. I commend to my gynecological brethren a remark which

shows Harvey's shrewdness. Speaking of certain uterine troubles he says:—

Women are peculiarly liable to these accidents, especially those among them who lead a luxurious life or whose health is naturally weak or who easily fall into disorders. Country-women and those accustomed to a life of labour do not become dangerously ill on such small grounds.

But Harvey was not unacquainted with the surgery of his day. In this same mine of clinical experience, the work on generation, will be found reference to cases of large sarcoceles, the treatment of which he had initiated by tying the afferent artery so as to limit the blood-supply. He subsequently removed the tumour by extirpation with the knife or the searing-iron.

Perhaps Harvey's conservatism as regards the relative status in his time of physicians and surgeons and his daring to have an independent opinion on surgical cases and even performing some operations (for in his will you will remember he left his surgical instruments to his friend Scarborough) may have roused the antipathy of the Barbers' and Surgeons' Company. At all events, they endeavoured to convict him of ill-practice in the case of an alleged fracture of the skull. There was no allegation of operation on his part, but only of erroneous opinion. But I do not gather that the Barbers' and Surgeons' Company supported their condemnation by any post-mortem evidence.

I think we may rest content that our Harvey, who was universally admitted to be a great anatomist and naturalist, was also an experienced pathologist, a learned physician, and he had the qualifications of a good all-round practitioner.

HARVEY AS COURT PHYSICIAN: CONTINENTAL JOURNEYS.

Harvey's Court duties were by no means strictly limited to medicine. As physician to the Court he was instructed to take two long and important continental journeys. The first of these was in 1630, when he accompanied the young Duke of Lennox on a rather prolonged tour, in which he was obliged to dodge the plague on several occasions, and was greatly impressed with the impoverishment of the countries through which they travelled.

The second continental journey made at the Royal Command was in 1636, when Harvey accompanied Thomas, Earl of Arundel, the Lord High Marshal, on an embassy to Vienna and Ratisbon, which was mainly concerned with efforts to secure the restoration of the King's nephew, the young Prince Palatine, to his proper status. About three years ago I had the good fortune to secure for this College 11 of Harvey's letters referring to a painful episode of this particular journey. Harvey's writing is very hard to read. It is the writing of a man of terse expression and who had no time to waste. The contractions are appalling. These letters are not quite so difficult as the few others which are extant, and they show that when he took pains he could make a tolerable script as well as express himself forcibly. They were written to Harvey's friend, Basil Lord Feilding, the eldest son of Lord Denbigh. Feilding was English ambassador at Venice, and it would appear had invited Harvey to visit him. Harvey looked forward to this visit with great delight.

Account of Second Continental Journey.

There exist in the Clarendon State papers fairly complete reports of this embassy on the official side, forwarded by Lord Arundel and his staff. It may interest you to follow Harvey's steps on this journey. Lord Arundel's reports are addressed to Sir Francis Windebank, one of the Secretaries of State for Foreign Affairs. The first is from Utrecht, in which Arundel informs Windebank that he has left his son at Leyden suffering from a stomach attack, but under the care of Dr. Harvey. They soon rejoined the party and we next hear from Arundel at Cologne, where he says he has been "this evening at the Jesuits fair new church and College where they used me with all civility. I found in the College little Dr. Harvey who means to convert them."

I think it is more than likely that this polemic related not to theology but to Harvey's doctrine on the circulation, for at the next stage, Nuremberg, Harvey writes a very courteous letter to Dr. Hoffmann in which he tries to disabuse his mind of certain misconceptions, and offers to give him a demonstration of the circulation. This letter is included in Harvey's published works, and shows that along with his scrupulous courtesy he could usefully blend a little

elegant sarcasm, for he begs Hoffmann, if he won't come to a demonstration or investigate by his own dissection, that he will not vilipend the industry of others nor charge it to them as a crime. "Do not derogate," he says, "from the faith of an honest man not altogether foolish nor insane who has had experience in such matters for a long series of years."

The first and second of Harvey's letters to Lord Feilding relating to this journey (now in the possession of the College) were written from Lintz, to which the Ambassador's party had gone on leaving Nuremberg. Here the first meeting with the Emperor Ferdinand took place. Harvey says he accompanied the Emperor on some hunting excursions. He speaks of him as a pious, good man, desirous of all love, quietness, peace, and justice! He refers to the impoverishment of the country by the Thirty Years' War and to the licence and oppression and anarchy which prevailed in Germany. Nevertheless, they had joined in a feast given by the Count of Milan, "the chief major-domo of his Majesty, where they drunk hard and had many expressions and many good wishes." There are ominous references to the plague and the fear of it.

The next move is to Vienna, where Harvey sees the Queen of Hungary and praises her two fine little babies. Then they go to Ratisbon where they have to await the assemblage of the Diet of the German Empire, which somewhat shadowy and dilatory body will have to discuss the questions respecting the young Prince Palatine's claims. From the Clarendon State papers we learn that everybody in Lord Arundel's mission was excessively tired by the long delay. Harvey seems to have been terribly bored and to have besought Lord Arundel to let him go to Italy during the vacancy, as he styles the waiting time. In one of the Clarendon despatches there is a reference to honest little Harvey whom the Earl is sending to Italy about some pictures for His Majesty.

This opens up a very interesting little bypath upon which other correspondence of Lord Feilding's throws additional light. Lord Arundel, as we know, was one of the great English virtuosos of that day and was the first to collect objects of art from Italy and elsewhere. His name is chiefly associated with the collection of Greek and Roman marbles which was ultimately secured for the University of Oxford by the mediatory efforts of John Evelyn. But he was a collector of pictures also. In some of the Feilding letters there are references to the pictures which at various times Feilding acquired for the King's collection, and the Marquis of Hamilton writes to Feilding on the same subject in which he delicately hints that Lord Arundel might take the opportunity of feathering his own nest and that he might even forestall Feilding in some of his bargains.

Detention in Lazaretto at Treviso.

At all events the invitation to Harvey to visit Lord Feilding at Venice may well have led to the extemporised mission which was entrusted to Harvey by Lord Arundel. But poor Harvey little dreamed of what was in store for him. He doubtless left Ratisbon in high spirits at his escape from the weary diplomatic tedium so trying to his active spirit. He was armed with *visé* to his passport and commendatory letters, but when having crossed the boundary of the Venetian territory he arrived at Treviso he writes to Lord Feilding that he was unjustly affronted, being stayed and commanded by the podesta to go into the lazaretto without any cause or suspicion alleged. It is clear that they were terribly and perhaps unreasonably afraid of the plague. Harvey produced his *visé* passport and recommendations from the King of Great Britain, from the Emperor, and from Lord Arundel, but the podesta would not look at them. Harvey refused to go to the lazaretto for fear of the infected persons who had been sent there before, and he ultimately elected to stay in the open fields. He scribbles his letter on the grass in the field and begs Lord Feilding to procure his release with all expedition.

He seems to have subsequently arranged to sleep in a poor open garden-house and to lie upon straw, but was by force and threatening of muskets compelled to go into the lazaretto into a very nasty room where the vetturin and his two servants and saddles lay!

The podesta, probably as the result of Lord Feilding's complaint, in three days' time sent a coach offering to take Harvey back to the poor garden-house (where he had been

before). Harvey did not conceal his irritation and indignantly refused to accept anything whatever from the town authorities, least of all a bed which he believed would have been an infected one, so he elects to sleep on straw. Subsequently the Senate of Venice sent him a message that he must stay where he was till further orders, without specifying the time. Meanwhile poor Harvey, having bad food and great exposure, had contracted sciatica. He seems to have been kept between a fortnight and three weeks, but we do not know the exact date or method of his release. He sent on his letters to Lord Feilding, and though he did not stay long in Venice he seems to have had a good time there, and then he went to Florence, where he enjoyed the hospitality of the Grand Duke, who lavished everything upon him that heart could wish.

Harvey's last letter to Lord Feilding was to announce his return to Ratisbon in November so as to be ready to accompany Lord Arundel on his return to England, his mission having turned out rather a fiasco.

It has hitherto escaped notice, but I find in the Clarendon Papers a letter from Sir John Borough in which it is stated that they were aware at Ratisbon that Dr. Harvey had been kept in quarantine at Treviso, "being not as yet, for aught we hear, released." His return to Ratisbon may have been somewhat surprising. A perusal of Harvey's letters and of the State Papers gives us a poor opinion of the estimation in which Englishmen were held in Charles the First's time in foreign lands, and we may be sure that Cromwell would not have brooked such scant consideration to any English subject during his rule.

Between the time of Harvey's leaving Florence and going back to Ratisbon we must, I think, intercalate his visit to Rome, where, under the hospitable roof of the English College, he dined with one who became a very staunch friend. This was Dr. Ent, who, in the evening of Harvey's life, secured for publication his work on Generation. The alleged visit to Rome with Dr. Ent, which Aubrey mentions, has been shown by Dr. Munk to be one of his many inaccuracies. The joint visit was the one just mentioned; it was in October, 1636. Harvey was back in London at the end of the year. He doubtless made other visits to Italy and probably to Padua.

THE CIVIL WAR: HARVEY AT OXFORD.

As Court physician Harvey accompanied the King for his Scotch Coronation. It is eminently characteristic that the chief interest for Harvey was not the ceremony nor the theological disputes, but his own visit to the Bass Rock in order to find out some points with regard to the Solan goose which then, as now, congregated on that island in great numbers. He probably also accompanied the King in his abortive warlike journey to Berwick in 1639 and perhaps again in 1640, but there do not appear to have been any important questions of natural history to be solved in those journeys, and I find no reference to them in Harvey's papers. The clouds were gathering for the Civil War, and Harvey's official association with the King rendered him *persona ingrata* not only to the Parliamentarians in the House of Commons, who tried to oust him from St. Bartholomew's Hospital, but to a mob who sacked and plundered his official lodgings in Whitehall. It is somewhat piquant and characteristic that Harvey, referring to this outrage, says the cause of his sorrow is that

"certain rapacious hands stripped not only my house of its furniture, but what is a subject of far greater regret with me, my enemies abstracted from my museum the fruits of many years of toil." "Whence it has come to pass that many observations, particularly on the generation of insects, have perished with detriment, I venture to say, to the republic of letters."

It has been assumed that Harvey's "Medical Observations," as well as some other papers, were destroyed by this mob. But Sir George Paget has drawn attention to the fact that Harvey himself speaks of these same "Medical Observations" being in his possession at the time when he writes, many years afterwards, his first letter to Riolaunus.

In regard to the historic incident of Harvey looking after the two young princes at the fringe of the battlefield of Edgehill, it is interesting to remember that his friend Lord Feilding had been removed from his Ambassador's post at Venice and was fighting on the Parliamentary side, whilst the Earl of Denbigh (Lord Feilding's father) was fighting for the King. There must have been many of Harvey's friends

on both sides of the great struggle, but it is noteworthy that throughout the four years, from 1642 to 1646, that Harvey was with the King at Oxford, there is no evidence that he took any part in political affairs, and there is no report of any utterance of greater resentment than is expressed in the one just quoted concerning his natural history collection.

Nothing daunted by the limitations of his surroundings at Oxford, he goes to visit his friend Bathurst at Trinity College and conducts with him daily observations on the development of the hen's egg. He was incorporated a Doctor of Medicine of Oxford, and during the last year was appointed Warden of Merton College. His brief opening address to the fellows, appealing to them to cultivate harmonious friendship amongst themselves and pledging himself for the development of the welfare of the College, is quite in harmony with Harvey's subsequent utterances at the College of Physicians. One interesting experience at Merton was his welcome to Scarborough, who had been expelled from his fellowship at Harvey's old college in Cambridge on account of his Royalist principles. Scarborough seems to have been not unnaturally interested in the lively military expeditions around Oxford of Prince Rupert and his fellow officers. Harvey said to him, "Prithee, leave off thy gunning and stay here and I will bring thee to practice." He probably recognised Scarborough's mathematical abilities and foresaw a great future for him, and Scarborough is said to have helped Harvey in some of his investigations.

In Clarendon's "History of the Rebellion" some of the most attractive pages are the character sketches of the chief men on both sides, and it is significant that Harvey finds no place; indeed, there is not a single mention of him in the whole of the work. Clarendon seems not to have concerned himself in writing his History with a single person who took no active political or military part in the great struggle. It seems remarkable in view of Harvey's long personal devotion to Charles I. in prosperous as well as in adverse days that when the surrender came he left him, and it is doubtful if he ever saw him again. But in fairness we must remember that Charles's movements, after the surrender, up and down the country were not under his own control, and very shortly the access of particular adherents and attendants was regulated, and Harvey may not have been permitted to join him, even if it were desired. At all events, he retired a saddened man of 68 to the quiet and rest provided him by his relatives in London and its neighbourhood, and his rich and influential merchant brothers may well have secured him safety and protection in his retirement.

HARVEY'S GREAT DISCOVERY.

I can well believe that a friendly critic might say, You have brought this discursive review of Harvey's career to its last stage and have said very little about his great discovery. To which I reply, That great discovery is inextricably linked with Harvey's long period of association with the College of Physicians, and to some points in that long period I now ask your attention.

It is probable that from 1602 onwards Harvey was working at his subject, and from 1609, when he was formally elected physician to St. Bartholomew's Hospital, he must have gradually acquired a reputation as an anatomist as well as a physician. In 1615, being then 37, he was appointed Lumleian lecturer to this College, a post which he held with certain inevitable absences until 1656, the year before he died. The Prelectiones which bear the date of 1616 are really the lecture notes for the first anatomical course which he delivered. His introduction, with its detailed categories of anatomical study, is interesting as a logical academic statement, but the practical instructions which Harvey laid down for his own guidance in method seem to me the last word as to the proper objects and limits of oral teaching and demonstration, and are a model to be utilised by every medical teacher of our own time. The special value of this MS., which deals chiefly with the viscera, is that we have here Harvey's first account of the circulation of the blood, the full exposition of which he gave in his printed book in 1628. For these 12 years Harvey had expounded his doctrines to our predecessors, and it is significant that from within this College there was no criticism or opposition to the full acceptance of those doctrines with the solitary exception of one licentiate, a certain Dr. Primrose, who was rather an abject pupil and follower of Riolaunus, the anatomical professor at Paris. Harvey demolished the

master Riolanus in the two disquisitions addressed to him, and the pupil needs no further consideration.

I need not dwell on Harvey's masterpiece, so brief, so terse, and so convincing, a model for all time of inductive reasoning. Let us never forget the two supreme doctrines which he established and which neither his predecessors nor his contemporaries had understood. (1) The circulation of blood from heart through arteries and back through the veins to the heart again. The pulmonary circulation, it is true, had been more or less apprehended, but it was reserved to Harvey to establish the true nature of the systemic circulation and to give the *coup de grâce* to the ebb and flow movement of the blood current, now this way, now that, which was the accepted explanation up to his time. (2) The muscular contraction of the ventricles, the real motive force of the circulation which had been conspicuously ignored and misinterpreted previously.

It is quite true that Harvey's view of the respiratory function was inadequate. For him it was summed up in cooling and ventilation, he never thoroughly faced the difference between arterial and venous blood, and it is doubtful if the meaning of oxidation had taken any definite shape in his scheme of life. But the day of chemistry was not yet, though it was not far off, and it was impossible for him without the help of the microscope to bridge over the space between the arteries and the veins. How he would have leapt for joy if Malpighi had only demonstrated the existence of the capillaries within Harvey's lifetime.

What was Harvey's method? It is certain that he had a wide and thorough acquaintance with the work of his predecessors, but he differs from them all in the courage and independence with which he really begins his work by ascertaining by his own senses what are the anatomical facts untrammelled by the statements of authority. He follows up his human anatomy by comparative studies of the circulatory organs of every animal that he can obtain. Then he reflects on the simplest explanation of the anatomical mechanism before him. Finally, he devises experiments, vivisectional and otherwise, to test and verify his hypotheses.

The question has been asked again and again, What was the relation between Bacon and Harvey? Bacon in his "Novum Organum," which was published in 1620, makes no reference to Harvey's discovery. Harvey's book appeared in 1628 and Bacon died in 1626, but one would have supposed that Bacon might have heard the account of Harvey's discovery during the four years which had elapsed since he first expounded it in the College. On the other hand, Sir Samuel Wilks is not, I think, correct when he says that Harvey had not read Bacon's works and owed nothing to Bacon. In the twenty-fifth exercise of Harvey's book on generation there is a sentence in which he proposes to review and analyse some of his previous results, and he says: "Wherefore I think it advisable here to state what fruits may follow our industry and in the words of the learned Lord Verulam to enter upon our second vintage."

If Aubrey is to be credited, Harvey "esteemed Bacon for his wit and style but would not allow him to be a great philosopher." "He writes philosophy like a Lord Chancellor," Harvey says, "but I have cured him." I think probably in spite of Bacon's many-sided enlightenment Harvey looked upon him as an academic litterateur who had no claims to eminence in practical investigation, and it may well be that Bacon's deep-rooted antagonism to Aristotle, which dated from the time when he was a student at the University, may have roused Harvey's distrust. "A man of genius lights his own fire," said John Foster, and in spite of all that has been said about every man's work being more or less dependent upon his environment and the heritage of the past, I do not think we are wrong in claiming that Harvey was a creative genius.

WORK ON GENERATION.

The work on generation has been spoken of as Harvey's aftermath, but in many ways it is more interesting than his *magnum opus* on the circulation, and I do not think it has received adequate appreciation from my distinguished predecessors. It tells us a great deal incidentally about the world experiences of a long and chequered career, and it shows Harvey to us on the speculative and contemplative side. The anatomical observations are, of course, circumscribed by the absence of microscopical methods, though it must be admitted that Harvey used such magnifying lenses

as he possessed to some purpose. There are some erroneous conclusions but not bad ones.

The introductions on the manner and order of acquiring knowledge and on the method of study are, I submit, masterpieces of lucid exposition. This work is interesting as showing Harvey's own estimate of his teachers.

"Foremost of all among the ancients," he says, "I follow Aristotle: among the moderns Fabricius of Aquapendente, the former as my leader the latter as my informant of the way." "For even as they who discover new lands and first set foot on foreign shores are wont to give them new names which mostly descend to posterity, so also do the discoverers of things and with perfect propriety give names to their discoveries." "And now I seem to hear Galen admonishing us that we should best agree about the things and not dispute greatly the words."

But with all Harvey's reverence for Aristotle's philosophy I believe he respected him most of all as a great naturalist and observer, and it is noteworthy that for him as well as for Fabricius and for Galen his reverence never prevented Harvey from pointing out their blunders in anatomical observation as well as in the deductions drawn therefrom. For example, in his fourteenth exercise Harvey goes so far as to suggest that on one point Aristotle had not himself seen the things he described, but received them second-hand from another observer, and that the periods were not given rightly.

HARVEY'S LATER YEARS: RELATIONS WITH THE COLLEGE OF PHYSICIANS.

As I have already indicated, from 1646 to 1657 his Court duties ended, his private practice relinquished, Harvey lived henceforward in retirement, first with one of his merchant brothers then with another in London or in the country near by. His brothers were substantial and influential people. In earlier years, when their father had left Kent and had come to live in London, Fuller tells us that—

As the sons got great estates they made their father treasurer thereof, who, being as skillful to purchase land as they to gain money, kept, employed, and improved their gainings to their great advantage; so that he survived to be the meanest of them of far greater Estate than himself.

In later years his brother Eliab looked after Harvey's money affairs, and he had no anxieties. We know little, alas, of Harvey's married life, but I think it must have been a happy one. His wife was the daughter of a cultivated and eminent physician, Dr. Launcelot Browne. They were married at the very outset of Harvey's professional career, and the wife died probably during the time Harvey was with the King at Oxford. The references in Harvey's will to his dear deceased loving wife show his solicitude to perpetuate her wishes, and his gracious desire that certain of his benefactions should be regarded as from her, though she had long since passed away, manifest his tender affection for her. It is clear that his sisters-in-law and all their respective households were unceasing in their care and solicitude, and the detailed and thoughtful remembrance in his will of all his relatives and their servants and of many poor folk is very touching. He was childless, but his care for his nephews and nieces was very marked.

This College was the chief interest of his old age. Besides being Lumleian lecturer, he had been at different periods Censor, Treasurer, Elect, and finally, when he graciously declined the proffered presidency, Councillor of the College. But the benefactions which I enumerated at the outset belong to the eventide of his life, from 1651 to 1657, and he seemed never to be able to give enough.

It is interesting to think of the devotion and long duration of his friendships. In old days he had nominated Dr. Edmund Smith as his substitute at St. Bartholomew's. Edmund Smith was with Harvey at Oxford, and now when Harvey was building at his own expense the costly and beautiful addition to the College edifice, it was Edmund Smith who really superintended the whole business for him, and whose name, at Harvey's desire, along with that of Dr. Prujean, the President, appeared on the commemoration inscription. I have referred to the brotherly attachment of Harvey, Ent, and Scarborough. Harvey's discoveries were at length warmly accepted by foreign universities and by foreign anatomists and scholars, notably by Siegel, Bartholin, and Descartes. Some of these foreign anatomists stoutly defended Harvey's doctrines against the few remaining obscurantists who were still in opposition. His friend,

Thomas Hobbes, said that Harvey was the only man whom he knew that had lived to see his own doctrine established in his lifetime.

Abraham Cowley's poetry is seldom read in these days, but his two poems on Harvey, based on intimate knowledge of the man and of his work, are full of genuine feeling and devotion. But the recognition most precious to him was the homage of this College. Fuller says of him he was not only Doctor Medicinæ but Doctor Medicorum. The homage of the College was shown during his lifetime by erecting a statue of Harvey. It was further shown by the large gathering of fellows who followed his remains beyond the City walls in the first part of his funeral. How many of them gathered round his tomb at Hempstead in Essex we do not know. The homage of his successors in this College was shown in 1883 by the reverent removal of his remains from the damaged outer vault where they lay to a sarcophagus in the chapel above.

THE WORK AND CHARACTER OF HARVEY.

Whilst we of this generation render our homage to our great benefactor, let us in a few words picture to ourselves the outstanding features of his work and character. First observe his pursuit of truth for its own sake, even though a complete solution were not forthcoming and quite independently of any ulterior benefit that might ensue. His discovery was one of those which, in Bacon's phrase, might fairly be called "light-bearing" rather than "fruit-yielding."

Amongst the objections which Harvey had again and again to combat in his work on the circulation was the ever-recurring question, *Cui bono?* Listen to his reply:—

I own I am of opinion that our first duty is to enquire whether the thing be or not, before asking wherefore it is. Meantime I would only ask how many things we admit in physiology, pathology, and therapeutics the causes of which are unknown to us? Whoever therefore sets himself in opposition to the circulation because if it be acknowledged he cannot account for a variety of medical opinions, nor in the treatment of diseases, give satisfactory reasons for the phenomena that appear or who regards it as in some sort criminal to call in question doctrines that have descended through a long succession of ages; to all of these I reply that the facts cognisable by the senses wait upon no opinions, and that the works of Nature bow to no antiquity, for, indeed, there is nothing either more ancient or of higher authority than Nature.

With what labour (he says) do we attain to the hidden things of truth when we take the averments of our senses as the guide which God has given us for attaining to a knowledge of his works, avoiding that specious path on which the eyesight is dazzled with the brilliancy of mere reasoning, and so many are led to wrong conclusions to probabilities only and too frequently to sophistical conclusions on things.

The doctrine of "spirits" dominated the physics and the physiology of that time. Harvey says—

As it is still a question what they are, how extant in the body, of what consistency, whether separate and distinct from the blood and solids or mingled with these—upon each and all of these points there are so many and such conflicting opinions that it is not wonderful that "the spirits," whose nature is thus left so wholly ambiguous, should serve as the common subterfuge of ignorance.

Persons of limited information when they are at a loss to assign a cause for anything, commonly reply that it is done by the spirits, and so they bring the spirits into play upon all occasions, even as indifferent poets are always thrusting the gods upon the stage as a means of unravelling the plot and bringing about the catastrophe.

Harvey's demolition of the doctrine of "spirits" marks an epoch in the history of science. Long sentences were the fashion of the time, but Harvey makes his meaning plain. He was keenly alive to the bondage of names and phrases. He was anxious to get the *knowledge of things* and not greatly concerned about names. He maintains that our business is not so much to inquire what a word properly signifies as how it is commonly understood. His writings are lit up by quaint and homely similes, but they are free from the pedantry of his time. Sir Clifford Allbutt thinks he was lacking in imagination. Perhaps that is so, and I think the result is that although some of his conclusions are incomplete and inadequate they contain remarkably little that is erroneous.

And about his character: there is in the opening sentences of his will a humble and definite statement of his Christian faith, and in his book on generation he expresses his conviction of the immanence of God. "He takes," Harvey says,

"the right and pious view of the matter who derives all generation from the same eternal and omnipotent Deity at whose nod the universe itself depends."

Aubrey says that Harvey, like his brothers, was choleric. You may say that the Treviso letters support that assertion, but remember he had great provocation, and he was a gouty subject. At all events, his choleric temper did not interfere with his courtesy and modesty in controversy nor with generous appreciation of the work of his contemporaries. Harvey's power of concentration and detachment in biological observation in adverse surroundings was amazing. He was patient and laborious in his investigations and reluctant to make any premature announcement of his conclusions. He was content to wait the judgment of time and enlightenment. He grew more and more fond of contemplation and even of solitude at times, because it gave him greater opportunity for contemplation. His love of family and of friends has been already noted, and to this may fitly be added his unfailing kindness to young men and readiness to advise them as to travel and books and his willingness to take trouble on their behalf.

The concluding parts of his last letters are very touching. The nearer he approaches the Great Divide the more he craves for the abiding remembrance and the affection of his correspondents. It is not only the old man eloquent, but the old man mellowed and gentle.

And now in these severe and strenuous days, when we trust that the "winter of our discontent" is soon to pass away, we recall once again the last exhortation of our great master. He bids us "ever to search out and study the secrets of Nature by way of experiment, and for the honour of our profession to continue in mutual love and affection amongst ourselves."

PENETRATING WOUNDS OF THE ABDOMEN.¹

BY T. CRISP ENGLISH, F.R.C.S. ENG.,

COLONEL, A.M.S.; CONSULTING SURGEON, BRITISH ARMY, SALONIKA.

GUNSHOT wounds of the abdomen form a subject of considerable importance, for there has been a decided difference of opinion as to the best line of treatment; some strongly urge operative measures whenever possible, and others believe that for most cases expectant treatment offers the best prospects. It may be safely said that extreme views in either direction will prove to be wrong, but the value of operative treatment under proper conditions is becoming increasingly obvious.

It is clearly an advantage that we should be able to discuss questions such as these before we have to deal with cases in large numbers out here, and the practical point to be borne in mind is, how shall we treat these injuries under the conditions which exist around Salonika. The only considerable experience of abdominal injuries is that gained in France, and in framing our conclusions we must draw largely from that experience, remembering that the conditions here may necessarily fall short of the very favourable conditions under which surgery is done in France at the present time.

It has been suggested that there is a tendency to attach undue importance to these injuries, considering that they form only a small proportion of the total number of wounds. Anyone, however, who has come into close contact with numbers of men recently wounded cannot but recognise the importance of the abdominal group; the cases owe this importance to their urgency, their high mortality, and to the fact that many lives may be saved by appropriate treatment.

Before discussing the relative merits of the different lines of treatment it is essential that the high mortality of penetrating abdominal wounds should be realised. The multiplicity and severity of the lesions make a high mortality inevitable whatever treatment be adopted; this fact is quickly grasped when one sees the extent of the injuries as revealed on the operating table or in the post-mortem tent. Available statistics all emphasise the same fact. It is obviously difficult to get complete statistics, but the following are given for what they are worth. They are based on figures collected by Colonel Cuthbert Wallace, C.M.G., consulting surgeon to the

¹ A paper read before the British Medical Society, Salonika.

Army, and those worked out in the unit to which I was subsequently attached. They refer to results during the first six months of 1915, and attempt to show approximately what proportion of patients with penetrating abdominal wounds reached England, *before operative treatment became general*.

Of 100 abdominal cases with penetrating and non-penetrating wounds admitted into field ambulances 30 died in the field ambulances, and these were presumably cases of penetrating wounds; the remaining 70 were taken to casualty clearing stations, where half of them, that is 35, were found to be penetrating cases. Of these, 18 died in the clearing stations and 17 were sent to the base. As far as can be judged from the information available the mortality of these cases in the base hospitals at that time was at least 35 per cent.; this means that of the 17 cases reaching the base at least 6 would die, leaving 11 to reach England. To sum up, it would appear that in 100 cases of abdominal wounds, 65 were instances of penetrating wounds—namely, the 30 that died in the field ambulances and the 35 diagnosed as penetrating cases in the clearing stations; 11 of these ultimately reached England. In other words, the mortality up to that stage was about 83 per cent.

Before coming to present-time conditions I will briefly refer to the treatment of these injuries before the present war. In civil life, of course, operation is the general rule, provided that the patient's condition allows it; all surgeons recognise that a man in civil life shot through the abdomen will usually have his best chance of recovery if he is operated upon. As regards the South African War it is difficult to get definite facts. Everyone is agreed that operations did badly, though it is not true that all ended fatally. As regards the penetrating wounds which were not operated upon one cannot but believe that most of them were fatal also, for rifle-bullet wounds of the abdomen are very fatal in the present war and in civil life, and presumably similar results occurred in South Africa. Surgeon-General Sir G. H. Makins, K.C.M.G., C.B., for instance, says that he saw no case recover in which the small intestine was certainly injured. The practical point is that operative treatment for these injuries failed in South Africa. The conditions were unfavourable; cases seldom reached the surgeon in their early stages; moreover, abdominal surgery was then 15 years younger than it is now.

In the early part of this war surgical work was influenced by the South African traditions, which naturally led most surgeons to believe that expectant treatment would give better results than operative treatment. Apart from this the conditions of warfare obtaining in the initial stages of the war were quite unsuitable for early operative treatment, and such work as was done was not a success. The cases were usually only operated upon in their later stages, and this fact, combined with the inevitable high mortality of abdominal wounds and the unfavourable experience of South Africa, discouraged operations.

In the spring of last year, however, when siege warfare had become established, operative treatment was restarted, and every facility that could be devised was supplied. Clearing stations were a short distance behind the firing line, the operating theatres were fully equipped for abdominal work, and arrangements were made that abdominal cases should be at once transported to these clearing stations.

Coming now to my personal experiences, I commenced work on these cases early in July of last year, being stationed at a casualty clearing station in France commanded by Lieutenant-Colonel V. J. Crawford, D.S.O. Here I had the pleasure of working with Captain J. B. Haycraft, the surgical specialist to the unit. As a rule, we took the abdominal cases admitted into the hospital alternately and assisted each other. In this unit the main operating theatre was in a room in a château; a large landing outside this room was boarded in and converted into a second theatre, which we reserved for the septic cases; in addition to this there were two operating tents. The facilities for abdominal work were excellent, and these we owed to Surgeon-General W. G. MacPherson, C.B., C.M.G., K.H.P., D.M.S. of the Army to which we were attached. In the first place the surgical equipment in that clearing station was as good as that of a civil hospital in England; anything that we needed for abdominal work was supplied at once. Secondly, we were greatly helped by an order that abdominal cases were to be sent at once to the nearest casualty clearing station, provided that the patients were fit to travel. The

proviso must be noted, for it was clearly for the medical officers of the field ambulances to use their discretion as to whether or not a patient was fit for transport. As a result of this order we got the majority of our cases within a short time of their injuries, often within 1½ to 3 hours.

When I started work in this unit I had the advantage of discussing the principles of treatment with Colonel Cuthbert Wallace. At first we were rather inclined to select cases for operation, watching those in which there was thought to be a fair chance of recovery under expectant treatment; but we found that most of those treated expectantly got into difficulties and usually died, and so we were led to operate upon most cases on principle as early as possible.

There were certain groups in which operation was clearly impossible or inadvisable.

1. Cases moribund on arrival; a proportion of cases reaching the clearing hospitals are unfortunately beyond surgical help. In some of these cases the condition may be so improved by infusion, warmth, and other methods of stimulation that operation becomes possible later on.

2. In injuries of the liver and kidneys when one felt sure that the hollow viscera had escaped, especially in rifle-bullet wounds, operation usually seemed contraindicated.

3. In the diaphragmatic group, cases in which the projectile appeared to have traversed the top of the abdomen, the diaphragm, and the lower part of the chest, expectant treatment is usually the wisest plan. Most of these patients have hemothorax; the abdominal lesions are difficult of access, and in all ways such cases are unfavourable for operative work.

4. There were two cases in which rifle bullets had apparently traversed the lower half of the abdomen, without producing abdominal symptoms or signs. As the physical condition in each case was perfectly normal operation was not performed, and these cases were evidently examples of a small group of fortunate cases in which the hollow viscera escaped injury. Reference to this will be made better.

The routine procedure adopted for these abdominal cases was as follows. On admission the patients were put comfortably to bed, warmed with plenty of blankets and hot-water bottles, given saline solution subcutaneously or by the rectum, and morphia if in pain. The majority were suffering from shock and the effects of hæmorrhage; these were kept for two, four, or six hours until they were better, and operation was not performed unless the radial pulse was of fair volume and its rate under 140. We were convinced that it is not advisable to operate immediately on patients with rapid pulse-rates; they nearly always require much repair work, and the prospects of success are decidedly better if time is spent in attempting to improve their general condition. Some patients presented few or no signs of shock, and these were operated upon as early as possible. In doubtful cases, when it was uncertain whether the peritoneal cavity had been penetrated or not, our rule was to explore the wound. By doing this we several times discovered intestinal injuries at an early stage before there were any external signs of their existence.

The Operation.

For wounds of the lower abdomen we found it a considerable help to have the pelvis raised, the best position being about 30° from the horizontal; for efficient treatment of bladder injuries this was essential. The incision was usually placed vertically in or near the mid-line, but of course it varied according to circumstances; the important point was that it should be sufficiently large to allow quick and free access to the injured parts.

After the opening of the peritoneal cavity the first step was to clean out the blood and other fluid, especially from the pelvis, which usually contained a large pool. Until this had been done it was difficult to see accurately the extent of the damage. A systematic examination of the abdominal contents was then rapidly made. The small intestine and its mesentery were first looked over from the caecal end up to the duodenum; the operator lifted out 7 or 8 inches of the intestine, examined it, and then left it for his assistant to return whilst he proceeded to examine the next loop. In this way there was never more than a foot or so of intestine outside the wound, and the whole of the small intestine with its mesentery could be examined in three or four minutes. Unless this systematic search is made it may happen that eight perforations are found and dealt with and the ninth overlooked. The search was next extended to the

colon, stomach, and any other viscera which might have been injured. Tears and perforations were treated by suture or excision of the intestine according to circumstances, and mesenteric injuries were carefully dealt with. Finally the pelvic cavity was usually irrigated with saline solution, some of which was left there, and a large drainage-tube inserted and secured by a stitch.

The patient's general condition was closely watched by the anæsthetist throughout the operation, and if necessary saline was given under the skin or intravenously. Speed is essential in these cases, for there is often much to do and the patients will not stand prolonged operations; also there are often other patients awaiting treatment. Thus, in a period of 24 hours during the battle of Loos 10 laparotomies and over 30 other operations were performed in one of our theatres.

The after-treatment of the cases required much common-sense and strenuous work. It is largely a matter of good nursing, and in this respect we were particularly fortunate. The administration of fluid in abundance is the most important point, for preference subcutaneously and by the mouth. The cases were usually kept in the hospital for 14 to 20 days, and then being convalescent were transferred to the base. Many of the patients were sent by ambulance barge, which we found the most comfortable method of transport for these abdominal cases. Necropsies were performed in the fatal cases unless pressure of work made this impossible; in this way much valuable information was obtained which helped us in our later operations.

Special Regions.

We will now consider certain points in connexion with the different regions of the abdomen.

In wounds of the upper abdomen the question of operation is often a difficult matter to decide, and each case requires careful consideration. It has already been said that when the projectile has wounded the diaphragm and caused a hæmothorax the case is usually unsuitable for operation, the chances of recovery being probably greater with expectant treatment. This is especially so if the right side is involved, for then the wounded liver may recover spontaneously and other visceral injury is unlikely. When the stomach area is involved exploration is advisable. It is true that clean perforations of the stomach may sometimes heal naturally, but the lesions are often tears rather than perforations, and other viscera, such as the splenic flexure, the spleen and the kidney, are frequently involved.

Wounds of the central and lower part of the abdomen are exceedingly fatal if left alone, and we made an invariable rule to operate on these cases provided that the patient was well enough to stand it. Multiple injuries of the small intestine were nearly always found—perforations or tears varying in number from 1 to 15 and injuries of the mesentery, often necessitating resection of the involved gut. In addition, wounds of the colon and other parts complicated matters in many cases.

A rapid survey of the extent of the intestinal and mesenteric injuries should be made, and the operator can then decide upon the best method of repair. Our experience led us to treat perforations and tears by suture whenever practicable, even if this caused some constriction of the gut. The extent of the injury or implication of the mesentery, however, will often make resection necessary, and then the point of importance is that the intestine should be resected well beyond the injured area, especially on the proximal side. Occasionally two portions of intestine require resection, and even with this the patient's life may be saved.

Wounds of the back, buttocks, and thighs which implicate the abdomen are very severe injuries, for it often happens that many loops of intestine are damaged. It is also obvious that the abdominal injury in these cases may be overlooked in the first instance, and serious delay may result. Colonel Crawford kindly arranged that all cases with wounds of the back, buttocks, and thighs should be admitted into the section of the unit reserved for abdominal cases; in this way early recognition of those in which the abdomen was involved became easy.

Prolapse of abdominal contents through a wound was almost always a signal of deeper internal trouble; a projectile which had so damaged the abdominal wall as to allow prolapse had almost invariably produced havoc inside.

An innocent-looking piece of prolapsed omentum commonly covered one or more large holes in a loop of intestine.

Spontaneous recovery of an intestinal perforation must be a very rare event, if it ever occurs. It is conceivable that minute punctures of the intestine might occasionally heal by natural processes, but lesions of this kind are not seen in warfare; rifle bullets and shell fragments produce full-sized perforations, tears, lacerations, and even complete division of the intestine. In that unit we saw and carefully examined a large number of intestinal injuries in all stages and we found not a particle of evidence to suggest that these lesions ever heal spontaneously. Surgeon-General Makins has sifted the evidence on this point in a paper published in the *R. A. M. C. Journal* for February last, and he concludes:—

It is indubitable that these results indicate that primary operation in properly selected cases affords the one and only chance of recovery for a patient who has received a perforating wound of the small intestine.

A small number of recoveries after wounds through the intestinal area are explicable in the following way. We came across two cases, and possibly a third, in which bullets or shell fragments had traversed the peritoneal cavity without causing any gross visceral injury. For instance, in one case a piece of shell the size of one's thumbnail entered through the loin and was found lying under the anterior abdominal wall wrapped in omentum; there had been a little hæmorrhage but no visceral injury of any kind. Such cases treated expectantly might lead one to suppose that injured intestine was recovering naturally; experience shows that in these cases the hollow viscera have escaped injury.

Expectant Treatment.

There will always be some cases in which expectant treatment is advisable or in which it is the only course practicable. The essential features of this treatment are absolute rest and measures to minimise the effects of hæmorrhage and shock—morphia and the regular administration of fluid. Morphia must be used freely, and as a rule its dose should be measured by the degree of pain. There is nothing to be said in favour of withholding fluids in these cases; the body tissues all cry out for fluid, and they cannot be expected to carry on if dry and parched. Fluid should be given by the mouth or rectum, or subcutaneously, according to circumstances. A patient hit in the lower abdomen or pelvis can take frequent small drinks of water with the best results; if hit in the region of the stomach he can have fluid by the rectum or into the cellular tissues.

The arguments in favour of expectant treatment for most cases break down when one goes into detail and gets at the plain facts. It is pointed out that patients recover without operation, but we now know that these patients form a very small minority. Many of the cases quoted as examples of recovery are instances of non-penetrating wounds, and the remainder mostly concern the liver and kidney; it has also been shown that very occasionally bullets may traverse the peritoneal cavity without causing injury to viscera. The belief that intestinal injuries could heal spontaneously has been disproved, and so one of the main arguments for expectant treatment has disappeared.

A statement sometimes advanced against operative treatment is that harm is done by transport, especially by way of increasing hæmorrhage. Obviously many cases are not fit for immediate transport to the clearing stations, and for this reason the proviso was inserted in the order as to the removal of abdominal cases. It is left to the medical officers of the field ambulances to decide whether the patients are well enough to stand the journey.

The Results of Operative Treatment.

It is obviously difficult to get complete statistics, but those available show beyond dispute the decided improvement which has occurred since operative treatment became more general. It seems fair to contrast the first six months of 1915 with the last six months.

In the first six months of the year we have already seen that the mortality of penetrating abdominal wounds in the field ambulances and clearing stations was 73.8 per cent. (48 out of 65 penetrating cases); and the mortality at the base hospitals appears to have been at least 35 per cent. during this period.

For the last six months of 1915 Colonel Outhbert Wallace has carefully collected the figures in the army to which he is attached. He has kindly sent me the results, and his figures show that the combined mortality in the field ambulances and clearing stations was 61.25 per cent.—a reduction of 12.5 per cent.

511 Penetrating Abdominal Cases, July–December, 1915, reported by Colonel Outhbert Wallace.

| | Total. | Re-covered | Mortality |
|--|--------|------------|-----------|
| Total cases | 511 | 198 | 61.25% |
| Operations | 310 | 143 | 53.9% |
| Operations on— | | | |
| Stomach | 16 | 9 | 44.5% |
| „ and intestine, &c. | 7 | 0 | — |
| Small intestine, suture | 25 | 14 | 44.0% |
| Small intestine, suture, plus other intestinal lesions | 12 | 3 | 75.0% |
| Small intestine, resection | 51 | 13 | 74.0% |
| Small intestine, resection, plus other intestinal lesions | 11 | 1 | 91.0% |
| Large intestine | 61 | 25 | 59.0% |
| Cæcum, suture | 4 | 4 | 0 |
| Solid viscera and genito-urinary organs ... | 65 | 42 | 35.0% |
| No operation— | | | |
| No indications, including liver and kidney cases | 56 | 55 | — |
| Moribund | 145 | — | — |

Cases now reaching the base have been sent there when apparently convalescent from operation, or if not operated upon when apparently safe from serious trouble. One may therefore assume that the base mortality will prove to be substantially reduced, and I think that one may safely say that the total improvement in the mortality is well over 20 per cent. The first six months of this year should give even better figures still, for now operative treatment for these cases has become generalised.

Conclusions.

1. Operations for penetrating abdominal wounds are not advisable unless they can be done in good surgical surroundings and by an operator with some knowledge of abdominal surgery; otherwise disasters will be more frequent than successes.

2. Patients with abdominal wounds should be sent to an operating station as quickly as possible, provided that they are fit to travel; their prospects depend mainly on the quickness with which this can be done.

3. Patients who are not fit to travel should be kept absolutely quiet, warm, and under the influence of morphia; saline infusion, hypodermically or otherwise, is most beneficial. They are then transported to the operating station as soon as their condition improves; the question is usually settled by the character of the pulse. If the pulse-rate is 130 or over, it is certainly best to keep them in the place where they are receiving their primary treatment until improvement occurs.

4. On reaching the place where they can be operated upon patients whose condition is good should be dealt with at once, otherwise two to eight hours should be spent in preparative treatment. Operation is never advisable if the pulse-rate is 140 or over.

5. The abdominal exploration must be systematic and quick: the duration of the operation should rarely exceed 45 minutes.

6. When good surgical conditions are obtainable operation is the best treatment in most cases, and must be done as soon as the patient's condition allows it. Be prepared for a high mortality, but know that early operative treatment will substantially reduce it.

As an appendix to this paper I will give a brief summary of cases operated upon during a period of three months, and in doing so I must thank Lieutenant-Colonel Crawford for permission to make use of these cases. With one or two exceptions the operations were done by Captain Haycraft and myself.

Summary of Cases Operated upon.

Total 71 Recovered 39; died 32.

1. Wound of ascending colon; drainage. Recovered.
2. Multiple wounds of small intestine, sutured; also perforation of bladder. Died.
3. Small intestine, prolapsed loop cleansed and returned. Recovered.
4. Wound of liver. Died of generalised gas septicæmia.
5. Stomach, tear of anterior wall sutured; prolapsed colon and omentum returned. Recovered.
6. Small intestine, perforations sutured. Recovered.
7. Wound of liver, empyema, drainage. Recovered.
8. Spleen pulped, removed; kidney also smashed. Died.
9. Small intestine perforated, sutured; omentum also prolapsed. Recovered.
10. Wound of liver. Recovered.
11. Cæcum, two perforations leaking freely, sutured. Recovered.
12. Small intestine, multiple injuries, excision; also amputation near hip for gas cellulitis. Died.
13. Small intestine, four perforations sutured. Recovered.
14. Small intestine, perforations and wounds of mesentery, excision. Died of gas cellulitis starting from buttock.
15. Bladder, extensive intraperitoneal tear, suture. Recovered.
16. Small intestine, multiple injuries, suture, also loop excised. Recovered.
17. Wound of base of mesentery, intraperitoneal hæmorrhage. Recovered.
18. Small intestine injuries, excision; also perforation of sigmoid flexure sutured. Died.
19. Small intestine, multiple injuries, excision. Recovered.
20. Wound of omentum by shell fragment, entering through loin. Recovered.
21. Ascending colon, tear sutured; retroperitoneal gas cellulitis. Died.
22. Wounds of stomach, splenic flexure and kidney. Died.
23. Wound of descending colon. Recovered.
24. Wound of liver. Recovered.
25. Small intestine, multiple injuries; suture and excision. Died.
26. Small intestine, tears, excised; perforation of rectum sutured. Died.
27. Wound of bladder sutured. Recovered.
28. Stomach, two perforations sutured; kidney pulped. Died.
29. Small intestine, many injuries; excision. Died.
30. Small intestine; perforations sutured. Died.
31. Small intestine; perforations sutured. Died.
32. Spleen, tear packed with gauze. Recovered.
33. Sigmoid flexure; perforation drained. Recovered.
34. Spleen, transverse colon, and liver wounded. Died.
35. Small intestine, multiple injuries; two loops excised. Died.
36. Cæcum, large perforation sutured. Recovered.
37. Small intestine, perforations sutured. Recovered.
38. Wound of liver; much hæmorrhage. Recovered.
39. Wound of liver and omentum. Recovered.
40. Small intestine, perforations sutured. Recovered.
41. Transverse colon, perforation sutured. Died of gas cellulitis.
42. Bladder torn; suprapubic drainage. Recovered.
43. Cæcum, perforation leaking freely, sutured. Recovered.
44. Small intestine, fistula; also gas cellulitis of abdominal wall multiple incisions and drainage. Recovered.
45. Stomach, tear sutured; also wound of liver. Recovered.
46. Small intestine; perforations sutured. Died.
47. Small intestine injuries; excision. Died.
48. Sigmoid flexure of colon; perforation sutured. Died.
49. Hepatic flexure of colon; perforation sutured. Died.
50. Small intestine injuries; excision. Died.
51. Transverse colon, perforation sutured; hepatic ducts torn. Died.
52. Stomach perforations, sutured. Recovered.
53. Liver and kidney wounded. Recovered.
54. Transverse colon; wound drained. Died.
55. Hepatic flexure, tear; drained. Died.
56. Multiple intraperitoneal injuries. Died.
57. Sigmoid flexure, perforation, drained. Died.
58. Sigmoid flexure, perforation, drained. Died of septic bronchitis.
59. Sigmoid flexure, perforation, drained. Recovered.
60. Sigmoid flexure, perforation, drained. Recovered.
61. Ascending colon, perforation, drained. Recovered.
62. Liver, wound of, much hæmorrhage. Recovered.
63. Small intestine, many injuries to bowel and mesentery; two portions excised. Died.
64. Sigmoid flexure, wound sutured. Recovered.
65. Duodenum, perforation sutured. Died.
66. Transverse colon, tear; colostomy. Died of pneumonia.
67. Splenic flexure, wound of, drained; also tear of spleen. Died.
68. Small intestine, perforations sutured; also perforation of sigmoid flexure; colostomy. Recovered.
69. Liver and base of mesentery wounded. Recovered.
70. Small intestine, perforations sutured. Recovered.
71. Small intestine, perforations sutured. Recovered.

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE.—The annual meeting was held on Oct. 19th, Lord Aberdare presiding. The loss in fees during the year ending June 30th amounted to nearly £500, but in spite of this the College had practically paid its way. Referring to the Welsh Medical School, Colonel Bruce Vaughan stated that the scheme, which was the outcome of Sir William James Thomas's gift, had been sanctioned, providing thus for 250 students. The buildings could be proceeded with, provided the Ministry of Munitions gave its assent. It was decided to pray the Ministry of Munitions to place no further obstacles in the way of the immediate erection of the medical school buildings. Only 104 men students are at present left in the College, 37 of whom are studying medicine.

THE TECHNIQUE OF THE AGGLUTININ TEST.

BY P. N. PANTON, M.A., M.B., B.C. CANTAB.,
CLINICAL PATHOLOGIST TO THE LONDON HOSPITAL; HONORARY BACTERIOLOGIST TO THE SPECIAL HOSPITALS FOR OFFICERS (LORD KNUTSFORD'S APPEAL).

DURING the past two years there has appeared in the columns of THE LANCET and elsewhere a considerable series of articles and letters dealing with the typhoid agglutinin reaction. The two main objects of these communications appear to be the following: (1) To advocate the employment by all pathologists of the same "standard" method of performing the test; and (2) to prove the superiority of the method originally devised by Professor Dreyer over all other methods, whether microscopic or macroscopic. A subsidiary question has developed in the course of these arguments, consisting in a dispute as to the behaviour of the agglutinin reaction in inoculated persons who subsequently develop a febrile attack. This article is mainly concerned with the two primary objects of the campaign.

1. *The employment of the same method by all users of the test.*—This has both advantages and disadvantages. The main advantage is pleasantly suggested by the idea that if all workers use the same method the results of all are strictly comparable. This is highly attractive in theory, but breaks down in practice for the following reasons.

(a) It is impossible to devise a method of sufficient simplicity to ensure comparable results from a number of individuals of widely different experience and capability. This objection alone would be sufficient to explode the theory for those who are experienced in the teaching of students and post graduates and are acquainted with the widely different results obtained by different users of any of the most simple tests in pathology. In dealing with an agglutination test it must be in the knowledge of most pathologists that when considering what value should be attached to a particular result of a test one asks not by what method was it done, but who did it.

(b) The enforcement of a particular pathological method upon all pathologists is naturally resisted by those who have for years been using a different method and who have carefully satisfied themselves of its value by laboratory and clinical experience. It is an infraction of true scientific independence, and to be resisted, unless the advantages are correspondingly great.

(c) The standard test must be capable of maintaining its standard over a long period, and in the case of Dreyer's method I doubt if this is possible. Different batches of the standard suspension of bacilli must be made from time to time, and the work done with different batches is compared under the same standard. These batches are bound to differ both in the number of bacilli they contain and in the agglutinability of the bacilli. The number of bacteria differ owing to the impossibility of determining with scientific exactitude the number present in a suspension. The number should, however, be approximately identical, as is the case when the suspension used is estimated simply by the opacity of the fluid. Minor variations in agglutinability taking place over a length of time cannot be accurately determined owing to the difficulty of comparison, since a stock agglutinating serum may also vary in strength with time. The main value of a standard test rests upon the use of a standard bacillary suspension, and in spite of the above objections such a standard is within limits possible, provided that one recognises that in the nature of things faulty batches will from time to time be sent out. Such standard suspensions could equally well be used by other methods, macroscopic or microscopic, if such a procedure were really necessary.

(d) The standard test must be simple, and it should be accurate. The simplicity of the test is essential in view of the complete lack of experience and technique among many who must use it at the present time. I do not wish to imply that a simple test is necessarily better than a complicated one, but I strongly object to a not uncommon superstition that a complicated test is necessarily preferable to a simple one. Dreyer's method, compared with other methods in common use, is cumbersome and complicated. Its accuracy is dealt with below.

2. *The alleged superiority of Dreyer's method.*—In an article in THE LANCET of Jan. 1st, 1916, Dr. Ainley Walker asserts that "beyond question the best and most useful of these methods [i.e., macroscopic methods] for accuracy, precision, simplicity, and safety was that devised by Dreyer in 1906." Dr. Walker, however, is more particularly intolerant of the microscopic method, and in the same article clearly and categorically gives his reasons why "the microscopic method entirely falls." His reasons are as follows:—

(a) The number of bacilli in the suspension used varies to an unknown degree at each examination. If this were true and important the objection could be got over by using the same suspension sterilised at a low temperature. But I believe that in practical hands the objection falls to the ground. Anyone thoroughly accustomed to making up bacterial suspensions and subsequently estimating them can judge very closely the strength of the suspension by the opacity of the fluid. Gross errors can be produced by using an almost solid suspension on the one hand, or a perfectly clear fluid on the other. Even in unskilled hands such an error as that hinted at by Dr. Walker is incredible.

(b) Cultures vary greatly in their susceptibility to agglutination. This objection applies to every method, and with reasonable care can be almost entirely avoided. It is found in practice that a strain of typhoid bacilli can be obtained and made use of over very long periods without any appreciable variation in its agglutinability, provided that the subcultures used are made upon similar media under identical circumstances. Of course, strains occur which cannot be agglutinated at all, but such are obviously avoided. Important variations in the strain used are always looked for, and tested for, from time to time. In my experience such variations in a good strain are most infrequent.

(c) The age of the culture, particularly if broth cultures are used, affects the agglutinability. Since a 24-hours-old subculture on a solid medium is, or should be, invariably employed, this objection carries no weight whatever, and should not have been made.

(d) Slight differences in the culture-media may affect the agglutinability of the bacillus. I have for years employed agar containing 5 per cent. of glycerine as the medium for subculture. The agar is standardised and made from the same stock substances. I have never been able to find any appreciable difference in agglutinability from this cause, and these objections (both (c) and (d)) are more likely to occur in the different batches of the "standard" suspensions. Such are Dr. Ainley Walker's objections to the microscopic method, but he adds the following statement: "The method cannot satisfactorily be made use of with killed cultures." It is a fact that cultures killed at too great a heat cannot be agglutinated by any method, but it is difficult to imagine that killed cultures can be agglutinated into masses visible to the naked eye but invisible under the microscope. I have, as a matter of fact, used the method with killed cultures.

On the strength of such objections, not one of which has any practical value, Dr. Walker concludes that "it follows that the microscopic method with fresh living cultures is liable to variations of some hundreds per cent." It would be difficult to find a more misleading statement based upon such flimsy evidence. The microscopic method has certain minor advantages over the macroscopic which I need not here discuss, but proceed directly to consider the possible disadvantages and inaccuracies of Dreyer's "standard" method.

If in spite of the objections natural to the enforcement of a standard technique such an enforcement were deemed necessary, one might at least expect a method which would offer certain advantages. For reasons stated above it should be simple and should afford few bad pitfalls for the unwary. Also it should be accurate. The simplicity of the method may be judged from the directions issued for it. The method is a very lengthy one, largely owing to the number of times the pipette has to be washed out—namely, six times with three different solutions, or 18 times altogether for a single test against one bacillus, and each washing must be thorough or grave errors arise. In practice a number of pipettes are doubtless used, and there is no warning against it, but since the pipettes provided differ seriously in drop capacity an even greater error is introduced. The dropping will depend further upon the pressure exerted on the teat and upon the angle at which the pipette is held, and no warning is issued on these points. Yet it is claimed that the technique can

safely be left in the hands of a laboratory attendant, a procedure which I am convinced should never be advocated even for the most simple manœuvres. In equally practised hands the method is, I believe, slower, more tedious, and more liable to accidental error than is the microscopic or other forms of the macroscopic methods.

The inaccuracies of the Dreyer method as at present employed are dealt with very exactly by Mr. R. Donald in THE LANCET of Sept. 2nd, 1916.¹ These errors are essential errors of the technique, and I will briefly recapitulate the more important of them. A quantitative agglutinin test depends for its accuracy upon the exactitude of the dilution of the serum to be tested. In the microscopic test these dilutions are made by means of a Wright's capillary tube and test, an extremely accurate method which is quite unaffected by variations in size or diameter of the pipette. In the "standard" method the dilutions are made by drop-measuring, and the errors which Mr. Donald points out are actual errors proved by careful measurement. They are as follows. The "standard" pipettes issued are of different sizes. The only three pipettes examined by Mr. Donald differed seriously, and the difference in outer diameter of two pipettes issued specially for the performance of an extensive research differed in their drop count by as much as 20 per cent. The directions given for diluting the serum with saline make no allowance for the difference in drop count of serum and saline, and in making a 1 in 10 dilution of serum there is a further error of 10 per cent. A similar error, but this time of 20 per cent., occurs in the drop-measurement of the "standard" suspension. These errors may balance themselves or they may not; it is a matter of chance, and the same workers, however skilled, using the two standard pipettes with the directions given would at one time have an error of 40 per cent. and at another time none at all. Now an error of 40 per cent. in measurement alone, when the measurements required can be made accurately by a simpler technique, is a very grave indictment of this "standard" method. It is true that the error is greatly reduced if one pipette is used throughout, but the facts are that the standard pipettes have been taken to be "standard," and have been used alternatively with such errors as are stated above, and if only one pipette is used the method becomes extraordinarily laborious.

While attacking the standard method in this manner, and in attempting to refute the attacks which have been made upon the microscopic method, I would like to confess that I have no doubts of the genuine idealistic views of the "standard" originators. I believe both methods have their minor faults and drawbacks, but I venture to support the view that we have not yet attained a method or a *matériel*, which warrants the general imposition of a fixed technique by a central authority.

The subsidiary question, none the less important, as to the behaviour of the agglutinin reaction in febrile inoculated patients, is one upon which I have little evidence to offer. I have looked up notes upon 100 consecutive cases from the Dardanelles. All of these patients had suffered from fever, the great majority being either paratyphoid or dysentery cases. All had been inoculated against typhoid at periods varying from one year to a few months previously. The typhoid agglutinin test was done in 72 of these cases. It was positive in 15, or in 20.8 per cent.; it was negative or partial—that is to say, gave a complete or partial agglutination in 1 in 20 dilutions and a partial or absent agglutination in 1 in 50 dilutions—in 16.7 per cent. It was completely negative—that is to say, it gave no reaction at all or only very slight clumping in 1 in 20—in 62.4 per cent. A 62.4 per cent. of completely negative tests in febrile cases who have been recently inoculated would seem to bear out the contention that the agglutinin content is diminished in such cases. I am unwilling, however, to include myself in the hymn of hate now being directed against Dr. H. L. Tidy on such evidence as I can offer. My cases are not sufficiently numerous, and they lack the evidence which

appears to me advisable—namely, the proof of the amount of agglutinin set up by the inoculation and present before the fever.

This paper would seem to be an attack upon the prominent supporters of the "standard" method; it is not so in reality. I have no doubt that the method as they use it gives reliable results, otherwise they would not advocate it. I merely wish to issue a plea that I and many others may be permitted to use different methods which in our opinion and experience are equally reliable. The whole dispute has arisen out of the very laudable desire to correlate the research of a number of workers. If such correlation were possible by the adoption of a standard method, and could be done only in this way, it would be invidious to criticise it. Yet I believe a simpler and more harmonious plan would be to allow to the workers a choice of any of the recognised methods, in all of which the standard is known, and to leave to a central authority the conversion of those standards into equivalent results.

Queen Anne-street, W.

A METHOD OF APPLYING THE WASSERMANN REACTION IN LARGE NUMBERS.

By P. FILDES, M.B., B.C. CANTAB.,

ROYAL NAVAL HOSPITAL, HASLAR; ASSISTANT BACTERIOLOGIST TO THE LONDON HOSPITAL;

AND

JAMES MCINTOSH, M.D. ABERD.,

BACTERIOLOGICAL LABORATORY, LONDON HOSPITAL.

(Both Working under the Medical Research Committee.)

ON several occasions recently we have been consulted upon the technique of the Wassermann reaction by those who propose to superintend or carry out these tests under the scheme promoted by the Local Government Board. Of recent years there have been few publications upon this subject, and therefore it may be opportune to give a detailed description of the technique without discussing the theory or rationale of the process in any way.

The details of the particular method which we describe are as introduced by one of us into the Royal Naval Hospital, Haslar. In this technique the reaction is reduced to the greatest possible simplicity. It is based upon that practised by us for several years, and which has been published *in extenso*.¹ The chief characteristic of our method is the use of a particular antigen composed of tissue extract mixed with cholesterol. Cholesterol was first used as an antigen by Fleischmann but apparently abandoned, and credit is due to Browning, Cruickshank, and Mackenzie for demonstrating first that cholesterol is capable of much increasing the specific action of another antigen. Browning and his co-workers amalgamated the cholesterol with "lecithin" extracted by themselves, but Sachs (1911) suggested the addition of small amounts of cholesterol to the organ extracts already in use.

In 1912 we published an extensive comparative test which we had carried out between various antigens, including Browning's and our own which we had founded upon the suggestions of Sachs. These tests showed that the formula worked out and suggested by us was more satisfactory than those hitherto in use and fulfilled the requirements of a "standard" antigen which would give comparable results in the hands of different workers. During the past four years this antigen has been extensively adopted, and is probably more widely used now than any other.

1. *Collection of the serum to be tested.*—About 0.5 c.c. of blood is required. This is very easily collected from the finger or thumb. The patient swings his right arm rapidly in order to drive the blood into the finger tips; a piece of fairly thin drainage tubing is then twisted round the thumb and two or three punctures are made with a glass "pricker" or surgical needle just proximally to the nail and towards the ulnar side. The blood is collected in a Wright's capsule of suitable size. Fuse the straight end of the capsule. Attach a gummed label inscribed with the number of the case and enter up the particulars in the book under the

¹ Since writing this paper I have read Dr. Atinley Walker's reply to Mr. Donald in THE LANCET of Sept. 23rd. The main inaccuracy is there eliminated on the supposition that only one pipette is used. As I point out, the use of one pipette renders the method extremely tedious, and certainly many users of the method have not confined themselves to one pipette. The directions, in alluding to the pipette as "the" pipette, cannot seriously be considered to convey any warning on the grave inaccuracy which arises if more than one be used.

¹ Brain, 1913, vol. xxxvi., p. 193.

same number. Put away the capsule into an efficient ice chest until required.²

At this point it may be strongly emphasised that it is of no value to spend time upon an elaborate Wassermann technique if the organisation permits of any possibility of mixing one serum with another. Grease pencil should never be used for writing numbers on glass. Every action involved in collecting the sample and "booking" it must be uninterrupted and rigidly according to routine.

2. *Materials required for the test.*—

a. Copper racks to hold 24 test-tubes, as sold by Messrs. Baird and Tatlock, 14, Cross-street, Hatton-garden, E.C., for this purpose.

b. Test-tubes, 4 × $\frac{1}{2}$, washed and finally rinsed in distilled water and dried.

c. 1 c.c. and 10 c.c. graduated pipettes, specially long, graduated to tip (Baird and Tatlock).

d. Washed sheep's corpuscles. Collect the blood from a freshly killed animal into a stoppered bottle containing a few pieces of glass rod and iron wire. Fill only half full. Shake continuously for sufficiently long to defibrinate it. The blood will keep in the ice chest for three or four days. When required, fill the glass centrifuge buckets with the blood and drive down the corpuscles. Remove serum and add saline; shake and centrifuge. This constitutes the first washing. There must be three washings in all. The first may be carried out the day before the corpuscles are required. After the third washing remove the saline without shaking up the corpuscles.

e. Guinea-pig complement. On the day of the test kill a guinea-pig by cutting its throat and collecting the blood in a saucer. The animal is first stunned *slightly* by knocking its head upon the edge of the table. Pour the blood from the saucer into a small conical glass. "Whip" to defibrinate with a piece of cotton-wool upon the end of an iron wire. Centrifuge and pipette off the serum.

f. Antigen. In two bottles A and B. Preparation of heart extract (A). Obtain a fresh human heart. With a pair of scissors cut off the muscular portions of the ventricles and elsewhere, but do not take fat. Mince these pieces and weigh them. Place in a mortar with a little sand and grind them up with absolute alcohol, using 9 c.c. of alcohol to 1 gm. of heart. Transfer the whole to a well-fitting glass-stoppered bottle, and shake occasionally for one and a half hours. Filter into another *well-fitting* glass-stoppered bottle through paper and preserve in ice chest. A deposit will be found to form and this may be filtered off again. Cholesterol solution (B). Take 1 gm. of pure cholesterol, such as Kahlbaum's, and place in a *well-fitting* glass-stoppered bottle. Add 100 c.c. absolute alcohol and put in the stopper tightly. *Shake and heat in water bath* until the cholesterol is dissolved.

g. Amboceptor. This will usually be purchased, although most sera upon the market are somewhat feeble in action.

3. *Standardisation of the amboceptor.*—To be performed with two different guinea-pigs to ensure maximum complement action. The standardisation should be repeated after several months.

a. *Materials.* 1. Saline solution. 2. Tube containing 0.5 c.c. guinea-pig's serum and 0.5 c.c. saline. 3. Tube containing amboceptor diluted 1 in 1000 thus: Tube a = ambo. 0.1 c.c. (exact) + saline 9.9 c.c. (shake); tube b = 1 c.c. from tube a + 9.0 c.c. saline (shake)—this is 1 in 1000. 4. Tube containing 1 c.c. of deposited washed corpuscles + 19 c.c. saline (shake). 5. Rack with 9 test-tubes 4 × $\frac{1}{2}$.

b. *Method.* Fill reagents into the tubes as indicated.

| No. of test-tube ... | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | Pipette to be used. |
|----------------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|---------------------|
| 1. Saline ... | 0.8 | 0.7 | 0.6 | 0.5 | 0.4 | 0.3 | 0.2 | 0.1 | 0 | 10 c.c. |
| 2. Ambo. (tube 3 b) ... | 0.1 | 0.2 | 0.3 | 0.4 | 0.5 | 0.6 | 0.7 | 0.8 | 0.9 | 1 c.c. |
| 3. Complement (tube 2) ... | 0.1 | 0.1 | 0.1 | 0.1 | 0.1 | 0.1 | 0.1 | 0.1 | 0.1 | 1 c.c. |
| 4. Blood (tube 4) ... | 0.5 | 0.5 | 0.5 | 0.5 | 0.5 | 0.5 | 0.5 | 0.5 | 0.5 | 10 c.c. |

Shake. Incubate for one hour at 37° C. and then read off the minimal hæmolytic dose—i.e., the first tube which is

absolutely clear. If the m.h.d. does not fall between 0.0001–0.0009 c.c. the test can be repeated, using the stronger dilution of amboceptor (tube 3 a). It is better, however, to use an amboceptor which does fall between these limits.

4. *Daily Routine.*—(1) Wash or complete washing of the blood corpuscles.

(2) Kill the guinea-pig and prepare the serum.

(3) Make up fresh saline solution.

(4) Standardise the complement (A) and antigen control (B). (All subsequent measurements under 1 c.c. are made with the 1 c.c. pipette; up to 10 c.c. with the 10 c.c. pipette; above 10 c.c. with a 50 c.c. measure.) *Materials:* (a) Four tubes in the rack, front row, for A; four tubes in the rack, back row, for B. (b) Complement diluted 1 in 24 (0.1 c.c. complement + 2.3 c.c. saline). (c) Complement 2½ times stronger (0.2 c.c. complement + 1.7 c.c. saline) for antigen control. (d) 5 per cent. corpuscle suspension containing amboceptor. This is made up as follows: The quantity required is 0.5 c.c. for every case to be tested + 10 c.c. Thus if 60 bloods are to be tested, 30 + 10 = 40 c.c. is required. The quantities will be as follows: (3) corpuscles (centrifuged deposit), 2.0 c.c.; (2) amboceptor, 4 m.h.d. per tube—i.e., if m.h.d. = 0.0005, 0.002 per tube × 80 = 0.16 c.c.; (1) saline 37.84 c.c. Every half c.c. of this mixture will contain 0.002 of amboceptor, the correct quantity per tube. Make up in the order of the numbers and shake after each addition. (e) Diluted antigen, made up as follows:—Rinse out and clean a 1 c.c. pipette with spirit. Take 0.3 c.c. of heart extract and 0.2 c.c. of cholesterol and place in a dry test-tube. Run in 7 c.c. of saline and shake.

Method: fill in the 8 tubes in the rack as indicated.

Front Row (A) for Estimating m.h.d. of Complement.

| | 1 | 2 | 3 | 4 |
|---|------|-----|------|-----|
| 1. Saline ... | 0.85 | 0.8 | 0.75 | 0.7 |
| 2. Complement (tube b) ... | 0.15 | 0.2 | 0.25 | 0.3 |
| 3. Corpuscles + amboceptor (tube d) ... | 0.5 | 0.5 | 0.5 | 0.5 |

Back Row (B) for Antigen Control.

| | 1 | 2 | 3 | 4 |
|----------------------------|------|-----|------|-----|
| 1. Saline ... | 0.35 | 0.3 | 0.25 | 0.2 |
| 2. Complement (tube c) ... | 0.15 | 0.2 | 0.25 | 0.3 |
| 3. Antigen (tube e) ... | 0.5 | 0.5 | 0.5 | 0.5 |

Shake. Put rack into a water bath at 37° C. for 10 minutes to see whether the front-row tubes are laking properly, and then transfer to the incubator to complete 1 hour. Read the m.h.d. of complement in the front row and put 0.5 c.c. of corpuscles (tube d) into each of the back-row tubes. Put into the water bath and note whether the tube behind the m.h.d. tube is laked (about 15 minutes or less). If so, continue as in following table:—

If m.h.d. is tube 1 use 0.5 c.c. of a 1 in 33 dilution of complement for each tube.

| | | | | | | |
|---|---|---|---------|---|---|---|
| " | 2 | " | 1 in 24 | " | " | " |
| " | 3 | " | 1 in 19 | " | " | " |
| " | 4 | " | 1 in 16 | " | " | " |

If not, take another guinea-pig.

5. *Preparation of serum for testing.*—While the complement is undergoing standardisation, or at any other time on the day of the test, the sera should be distributed into the tubes. The numbered capsules are centrifuged and a series of test-tubes are set out in the racks, each numbered to correspond to the capsules. The numbering of the tubes must be indelible, and is best carried out by Donald's method. 1. Warm the tube in the flame. 2. Inscribe a bold figure on it with ordinary blue-black ink. 3. Burn in the ink by heating in the flame to a point short of the fusing temperature. From each capsule transfer 0.1 c.c. of clear serum to the corresponding tube. This is conveniently done with Donald's dropping pipettes, thus:—1. Pull out a piece of glass tubing into two pipettes. 2. Pass the pipette through a particular hole in a wire gauge plate, when it engages cut it off flush with the plate. The actual hole to be used is found once and for all by experiment. A pipette made in No. 53 Stubbs will deliver 0.1 c.c. of serum in 4 drops. Always hold the pipette vertically and wash with water between each serum. When the sera are all filled in make the tubes into a bundle in some safe and convenient manner and suspend them in a water-bath standing at 55°–56° C. for 30 minutes. Then replace them in the racks in sequence. When testing cerebro-spinal fluid use twice as much and do not heat it.

² If the ice chest is inefficient or if the sera have been sent by post or badly collected, it is better not to keep the capsules for several days but to centrifuge them at once and keep the serum separate from the corpuscles.

6. *Preparation of the reagents for use.*—*a.* When the complement is standardised make up a sufficient quantity of the correct dilution to allow 0.5 c.c. for each tube and a little over. *b.* Also make up exactly the same quantity of diluted antigen as shown in the table. Mix in the manner already described for antigen.

| No. of tubes. | C.c. | Heart. | Cholesterin. | Saline. |
|---------------|------|--------|--------------|---------|
| 30 | 15 | = 0.6 | + 0.4 | + 14.0 |
| 40 | 20 | = 0.8 | + 0.53 | + 18.6 |
| 50 | 25 | = 1.0 | + 0.67 | + 23.3 |
| 60 | 30 | = 1.2 | + 0.8 | + 28.0 |
| 70 | 35 | = 1.4 | + 0.93 | + 32.6 |
| 80 | 40 | = 1.6 | + 1.06 | + 37.3 |
| 90 | 45 | = 1.8 | + 1.2 | + 42.0 |
| 100 | 50 | = 2.0 | + 1.34 | + 46.6 |
| 110 | 55 | = 2.2 | + 1.47 | + 51.3 |
| 120 | 60 | = 2.4 | + 1.6 | + 56.0 |
| 130 | 65 | = 2.6 | + 1.73 | + 60.6 |
| 140 | 70 | = 2.8 | + 1.86 | + 65.3 |
| 150 | 75 | = 3.0 | + 2.0 | + 70.0 |

7. *The test proper.*—Mix the diluted complement and antigen together, and then, *without delay*, measure 1 c.c. of the mixture into every tube. Shake. Incubate for one hour in the air incubator. Add 0.5 c.c. of the corpuscle-amboceptor mixture to each tube. Place the racks in the water-bath and read results when some are quite laked and others quite opaque—i.e., in about 10 minutes.

8. *Reading results.*—When judging between complete inhibition and slight hemolysis, depend more upon opacity than colour. Describe the inhibiting sera as ++++ (complete); +++; ++ or +. +++++ and +++ will be diagnostic of syphilis, ++ and + will be more or less doubtful when the tester has no personal knowledge of the case. If, however, the case is known to have had syphilis, ++ and + assume much more importance. The great majority of cases give ++++ or 0.

THE OCCASIONAL ABSENCE OF A RISE OF TEMPERATURE FOLLOWING THE ADMINISTRATION OF DIAGNOSTIC DOSES OF TUBERCULIN TO TUBERCULOUS PERSONS.

By DUNCAN FORBES, M.D., B.Sc. EDIN., D.P.H.,

MEDICAL OFFICER OF HEALTH OF BRIGHTON;

AND

C. W. HUTT, M.A., M.D. CANTAB., D.P.H.,

SENIOR SCHOOL DOCTOR AND ACTING TUBERCULOSIS OFFICER, BRIGHTON

It is well recognised that a local reaction and rise of temperature following the administration of tuberculin does not necessarily indicate the presence of an active lesion, signs of a focal reaction alone giving any evidence likely to be of assistance in the diagnosis. On the other hand, many believe that active disease can definitely be excluded if the usual diagnostic doses of tuberculin are not followed by any marked rise of temperature. Our reason for sending these few notes is to emphasise the fact that patients suffering from active tuberculosis and who have not been previously treated with tuberculin may have no rise of temperature of even 1° F. above normal following the administration of diagnostic doses of tuberculin. In other words, the absence of a temperature reaction after the administration of maximum diagnostic doses of tuberculin does not prove the absence of active tuberculosis.

CASE 1.—The patient, a male aged 44, had a history of cough on and off for ten years, more marked since November, 1913. In July, 1914, he was admitted to the sanatorium for observation. He had received no tuberculin treatment prior to admission. There was impaired resonance at the right apex, but no sign of active disease. As some doubt existed as to the diagnosis, a short time after admission, at intervals of three and four days, 0.00002 P.T.O. and $\frac{1}{2}$, $\frac{1}{2}$, 1, 2, 5, and 10 milligrammes of tuberculin (T.) were given. The four-hourly chart showed no rise of temperature, except on the day following the $\frac{1}{2}$ and 1 milligramme doses, when the mouth temperature rose to 98.6° and 99.2° F.; on two occasions prior to the administration of tuberculin a temperature of 99.2° had been recorded. The local reaction was slight. The patient's weight steadily rose from 55.5 kilos on July 17th to 60 kilos on August 20th, when he

was discharged. A trace of albumin but no tubercle bacilli were found in his sputum at that time.

The patient's condition remained stationary until November, 1915, some 15 months later, when he was readmitted with definite crepitations at the right apex and tubercle bacilli in the sputum. On Dec. 20th, 28th, and 31st, and Jan. 6th $\frac{1}{2}$, $\frac{1}{2}$, 1, and 5 milligrammes of tuberculin (T.) were administered, followed by no increase of temperature over the normal, except on two occasions, 99° being recorded on the third day after the $\frac{1}{2}$ and 5 milligramme doses; a temperature of 99° had been recorded on Dec. 11th a short time prior to the injections. On Jan. 9th there was increase of cough and sputum but no rise in temperature. The sputum was then sent to the Lister Institute for examination in order to exclude the possibility that saprophytic acid-fast organisms had been mistaken for tubercle bacilli; the guinea-pigs inoculated showed macroscopic signs of tuberculosis.

This case seems to prove that the routine diagnostic doses of tuberculin may not be followed by a temperature appreciably over the patient's normal temperature (*a*) at an early stage of the disease when tubercle bacilli cannot be found in the sputum, and (*b*) at later stages when these are present and even when a focal reaction indicated by increase of cough and sputum is caused.

CASE 2.—The patient, a male aged 2, was admitted suffering from spinal caries and healed tuberculous abscesses on the foot. He received $\frac{1}{2}$, $\frac{1}{2}$, and 1 milligramme of tuberculin (T.), the highest subsequent temperature being 98.6° F. Five months later an abscess formed on the dorsum of the foot, broke down, and remained open for some time. In this case the maximum dose administered was 1 milligramme, but the child was only 2 years of age.

In this connexion it is interesting to note that of the animals infected with human tubercle bacilli and tested with homologous tuberculin the following gave a temperature reaction¹ (rises of 0.9° C. over the normal): 107 of 124 calves, or 86.3 per cent.; 6 of 6 goats, or 100 per cent.; 10 of 11 pigs, or 90.9 per cent.; and 4 of 4 horses, or 100 per cent. Evidently neither in man nor in animals does the absence of a temperature reaction following tuberculin exclude active tuberculosis.

Brighton.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF ELECTRO-THERAPEUTICS.

Exhibition of Case and of Skiagrams.—Gas Gangrene.

A MEETING of this section was held on Oct. 20th, Dr. G. HARRISON ORTON, the President, being in the chair.

Dr. E. P. CUMBERBATCH showed a female patient, about 60 years of age, for the purpose of illustrating what could be accomplished by the diathermic cautery in cases of malignant disease. In 1913 she came to him with a rodent ulcer on the scalp, measuring 1 by $\frac{1}{2}$ in. in diameter. Zinc ionisation, repeated six times, produced no benefit; neither did a course of X ray treatment. A combination of both those methods was equally barren of results, for at the end of 10 months the diameter of the ulcer had increased to 1 $\frac{1}{2}$ by 1 $\frac{1}{2}$ in. Accordingly, in March, 1914, he commenced the use of the diathermic cautery, cauterising with it the edges of the ulcer and the granulations at the base. There could now be seen a central area of parietal bone occupying the base of the ulcer, and around that the tissue was apparently healthy. That greatly improved condition had persisted for a year and seven months. In treating bone cases Dr. Cumberbatch insisted on great care being taken not to allow the diathermy to damage the periosteum.—Dr. W. J. TURRELL, in discussing the treatment, said that no attempt should be made to treat the whole growth at once, when the wound was a large one, but that treatment should be proceeded with in stages, so that the effect of the previous application could be assessed before entering upon another.

Dr. H. A. ECCLES showed, by means of the epidiascope, a valuable series of skiagrams of Fractured Jaws, from a

¹ Final Report of Royal Commission on Tuberculosis, Part II. Appendix Report on Tuberculin Tests.

special jaw section of the large military hospital to which he was attached. Every patient was radiographed at the earliest opportunity after admission, and in many cases three or four pictures were taken to determine the effect of the treatment or the presence of sequelæ. The chief purposes served by radiography in jaw cases were: to diagnose fracture, to ascertain the position of the fragments before and after replacement, to ascertain whether roots of teeth were present in the fracture, their presence being a fruitful cause of non-union; to determine the degree of union, the condition of the bone, and the state of the bone-graft; and to detect and localise foreign bodies. Some 60 per cent. of these cases were returned to the front from the department.—Several members discussed the contribution, and Dr. EOLLES replied.

DR. AGNES SAVILL contributed a short paper on her experiences in a hospital near the firing line of cases of Gas Gangrene, and by means of a series of skiagrams demonstrated the peculiar appearances seen in this terrible disease. Associated with gas gangrene were so many micro-organisms that it would be difficult to assign specificity to any one of them; and pathologists were now working at the problem in order to discover the direct and the contributory causes of the two types, the localised and the massive. Of the cases admitted between July and the middle of September 304 were found to contain the micro-organisms usually found in gas gangrene, and over 100 of them presented on admission definite clinical signs of gas. At the hospital every wound was reported upon by a bacteriologist, and cases presenting clinical signs which needed surgical intervention were operated upon as soon as possible, and those which had a mixed aerobic and anaerobic infection were given operative precedence over the others. In the most severe and fatal cases the radiologist was able to detect a fine striation dividing the muscular fibres; it was seen only about 24 hours before death. A French worker considered that the *vibrio septique* was the causal organism of gas gangrene, but *B. perfringens* (in a large proportion), *aerogenes capsulatus*, *sporogenes*, and *histolyticus* had all been found in such cases. When *sporogenes* was present the skiagram showed a cloudy shadow or small bubbles. Only two of the cases of the numerous series exhibited the fine striation lines. At present the surgeon could rely upon the radiologist in cases of this disease in much the same way as the physician could rely upon the bacteriologist in a case of suspicious throat.—A discussion followed.

New forms of apparatus were also shown.

LONDON DERMATOLOGICAL SOCIETY.—At a meeting of this society on Oct. 17th Dr. W. Knowsley Sibley explained in his presidential address that the objects of the society were consultative, educational, and social. He appealed to the profession to stand as a body against the invasion of all German importations, this stand to be taken in common with our Allies.—Captain W. Griffith, R.A.M.C., showed three cases of Dermatitis Herpetiformis and one of Recurrent Summer Eruption.—Dr. Morgan Dockrell: A case of Generalised "Chorionitis" in a man aged 55, a telegraph fitter. He attributed the cause as being due to exposure; the condition had improved with radiant heat baths and internal treatment of thyroid extract 15 grains a day and injections of pilocarpine 1/6 grain three times a week.—Dr. J. L. Bunch: 1. A woman, aged 43, with a Swelling behind the Right Ear involving the Anterior Part. He suggested that the case might be one of lymphangioma. 2. A boy aged 12 with Vitiligo.—The President: A case of Lichen Planus becoming atrophic.

HARVEIAN SOCIETY.—At the Harveian Society of London on Nov. 2nd Dr. E. Farquhar Buzzard will read a paper entitled "Warfare on the Brain"; on Nov. 23rd Mr. Robert Jones will open a discussion on the Treatment of Fractures; and on Dec. 7th Dr. B. H. Spilsbury will read a paper on Sudden Death.

LITERARY INTELLIGENCE.—Messrs. Cassell and Co., La Belle Sauvage, London, E.C., announce the early publication of a sixth edition of "Clinical Methods: A Guide to the Practical Study of Medicine," by Dr. Robert Hutchison and Dr. Harry Rainy. The previous edition was published in 1912.

Reviews and Notices of Books.

(1) *Pulmonary Tuberculosis.*

By MAURICE FISHBERG, M.D., Clinical Professor of Tuberculosis, New York University. Illustrated. Philadelphia and New York: Lea and Febiger. 1916. Pp. 639. Price \$5 net.

(2) *Pulmonary Tuberculosis in General Practice.*

By HALLIDAY G. SUTHERLAND, M.D. Edin., Tuberculosis Officer for North Marylebone and Medical Officer to the St. Marylebone Tuberculosis Dispensary. Illustrated. London: Cassell and Co. 1916. Pp. 290. Price 10s. 6d.

It is becoming increasingly recognised that in order to command success the treatment of pulmonary tuberculosis must be continuous, and this necessity is obvious when it is borne in mind that infection is, as a rule, acquired in early youth, while the risk of the disease developing or relapsing lasts into old age. Tuberculosis is nearly conterminous with life itself. The treatment of the patient—or rather the supervision of the whole life of the tuberculous subject—cannot therefore be left to the consultant or to the sanatorium officer, but must in the main be the concern of the family physician, who alone has the opportunity of dealing with the case as a continuous whole.

(1) Dr. Fishberg has written his book to supply the general practitioner with information concerning the etiology, diagnosis, prognosis, and treatment of pulmonary tuberculosis, its clinical forms and common complications. An experience of 18 years in dealing with tuberculosis problems in New York City convinced him that the practitioner can, and should, do more than attempt to recognise the disease early in order to send the patient to an institution, and that careful home treatment is productive of practically the same results as institutional treatment, and can be given at a smaller cost to the patient and to the community. His book is intended to equip the practitioner with the information which will enable him to carry out this home treatment effectively. Dr. Fishberg writes with authority as one who has practical knowledge of the things of which he writes. He has no special axe to grind, and his book may be read from beginning to end without discovering that he has invented or improved any item in the whole treatment of the tuberculous patient; but there are few pages which do not contain some illuminating suggestion or which do not throw new light on some old aspect of the disease. Koch's experiment on himself in which he found that 250 c.m.m. of old tuberculin produced severe febrile reaction is well known and the correct deduction frequently drawn, but we do not remember having read elsewhere the statement that the necropsy showed him to have suffered from extensive pulmonary tuberculosis.

Dr. Fishberg, in emphasising the lesson that good food is a more important factor in recovery than good air and even good residence, quotes the remarks of an American historian, W. Garrott Brown, who succumbed to phthisis, on the difficulty of discovering the place where he could breathe freely and constantly the right kind of air and at the same time eat in abundance the right kind of food. He made the melancholy discovery that Americans who could be induced to "take boarders" who are sick were, many of them, such as had already failed to minister acceptably to boarders who are well.

The arrangement of the book is simple and easy to follow. Dr. Fishberg makes no attempt at elaborate classification of the clinical forms of tuberculosis. He recognises that to be of practical service the classification must have a prognostic value, and he therefore describes the symptoms under the seven simple headings: chronic phthisis, incipient stage; chronic phthisis, advanced stage; acute phthisis; fibroid phthisis; abortive pulmonary tuberculosis; pulmonary tuberculosis in children; and phthisis in the aged. It is not very deep of the author, but the practitioner will thank him for it. Physical signs are dealt with as though Dr. Fishberg took a personal interest in them: the methods of Krönig and Goldscheider come into their own, and the chapter on percussion is greatly helped by the excellent and artistic illustrations. Fig. 60 is quite brilliant in its helpfulness. The value of medicinal treatment is duly recognised by the author, who finds, indeed, no panacea in drugs, but agents

which exert a beneficial influence on some of the annoying clinical phenomena. Dr. Fishberg is frankly sceptical of the value of tuberculin in treatment, and considers that the general practitioner should not use it at all. His book must not, therefore, be consulted as a guide to its administration. To the subject of artificial pneumothorax he devotes more than 30 pages, on account, as he says, of the efficacy of the treatment in selected patients where everything else has failed to afford relief. This section is a safe guide to practice. We cannot conclude without paying a tribute to the author's wide reading and his catholicity of view, which renders his book of equal value in whatever country it is read. The text and illustrations are both without blemish.

(2) Dr. Halliday Sutherland has also written his book for general practitioners and has succeeded in making it attractive. He has reduced the pathological section of his subject to its smallest dimensions, limiting it to the minimum necessary for the interpretation of clinical signs. This has given him adequate space to devote to diagnosis and the course of the illness, describing symptoms and physical signs in a clear and interesting manner. We wonder whether the author is really well advised in adding yet another table of graphic signs and abbreviations to the many which are already available and which seem to some to darken knowledge. We do not know whether Dr. Sutherland has shown his polyvalent tuberculin to present such practical advantage over other forms of tubercle vaccine as to deserve a place where the room is already so crowded. But it would be captious to refuse the author the right to lay stress on some of the points to which he has himself paid special attention. The book is a most useful guide for the general practitioner and contains much essential advice in a small compass.

LIBRARY TABLE.

Manual of Operative Surgery. By JOHN FAIRBAIRN BINNIE, A.M., C.M. Aberd., F.A.C.S., Surgeon to the Christian Church, the German, and the General Hospitals, Kansas City, Mo., &c. Seventh edition, revised and enlarged. With 1597 illustrations, a number of which are printed in colours. London: H. K. Lewis and Co., Limited. 1916. Pp. 1363. Price 32s. net.—It can hardly be necessary to say much about this edition of a well-known work, though, as it is possible that some surgeons do not know it, we may mention that it contains an epitome of all the operations which may be performed in surgery; it gives briefly, but in sufficient detail for the practising surgeon, the methods of performing an immense number of operations. It is not intended so much for the student as for the surgeon who, being called upon to perform some operation which he has not done before, will find in this volume the facts which he needs. The present issue contains a few new features, and it has been brought thoroughly up to date. A chapter on the surgery of the heart has been added, and a chapter on war surgery, written by Dr. Walter Sutton, also finds a place. The book can be thoroughly recommended to all surgeons.

Anatomía de los Conductos Biliares y de la Arteria Cística. By Dr. PEDRO BELOU, Profesor Titular de Anatomía Descriptiva de la Facultad de Ciencias Médicas de Buenos Aires. With 102 figures and 21 plates, 14 of which are coloured. Buenos Aires: Imp. "Oceana," Calle Chile 525. 1915. Pp. 302.—This admirable monograph deals exhaustively with the anatomy, descriptive, surgical, and comparative, of the biliary apparatus. Professor Belou has made an excellent arrangement of his subject, giving an exhaustive account of his personal investigations, and summing up the previous literature. As a treatise the book is without a rival, and as a monograph it comes as near perfection as it is possible to attain. All the illustrations are good; some are drawings, some are photographs, and all are well reproduced. The coloured plates rank among the most beautiful anatomical representations published. The press which prints and issues a book of this nature is to be congratulated, for the greatest care has been lavished upon every detail which goes towards the making of a good book, and a good book it undoubtedly is.

Wheeler's Handbook of Medicine. By WILLIAM R. JACK, B.Sc., M.D. Glasg., Physician to the Glasgow Royal Infirmary. Fifth edition. Edinburgh: E. and S. Livingstone.

1916. Pp. 552. Price 8s. net.—The Scotch medical schools are fortunate in possessing good text-books of moderate size, and this is one of them. Wheeler's Handbook has now reached its fifth edition, and Dr. Jack states that the changes made in the book since 1894 have been so great that little now remains of Dr. Wheeler's writing. The additions to the present issue are chiefly apparent in the sections on cardiac disease, where the newer diagnostic instruments are figured and described. Increased space has been given throughout to the paragraphs on treatment, dealing both with newer and more established methods. It is, of course, possible to make minor criticisms regarding arrangement of subject-matter: poliomyelitis surely deserves a place among the specific infectious diseases due to filter-passers. And one of the lessons of the present war, that the infection of typhus is carried by lice only, is not emphasised. The limit, too, of compression is reached in such a sentence as (describing artificial pneumothorax): "The gas is at first rapidly absorbed, and hence must be reintroduced at increasing intervals." There are a few slips: T.O.A. is not the symbol for old tuberculin. But these are minor blemishes in an otherwise excellent handbook.

CURRENT GERMAN MEDICINE.

Effect of the War on the Birth-rate.

THE effect of the war, according to Dr. G. Mamloch's reading of the recent German official returns (*Deutsche Medizinische Wochenschrift*, No. 38), began to make itself felt on the birth-rate in the second quarter of 1915. The number of live births in the total of 26 German cities of over 200,000 inhabitants fell from 66,032 in the first quarter of 1914 to 42,723 in the last quarter of 1915. For the whole year 1915 the total was 49,749 less than in the previous year, a reduction of 19.3 per cent. This percentage diminution was highest in Chemnitz (27.2), Nürnberg (27.1), Hamburg (23.6), and lowest in Mannheim (14.2), Berlin-Schöneberg (13.1), and Kiel, where it only amounted to 7.5. In Berlin itself the deficit of births was proportionately vastly greater than in the war years 1870-71. Some of this diminution in the number of live births was made good by a reduction in the infantile death-rate, which was 14.0 in 1915, reckoned on 100 live births, as compared with 15.3 in 1914. Such a low infant mortality figure as that of the war year 1915 had never previously been observed in Germany. A number of towns certainly showed high figures—e.g., Königsberg, 19.6; Magdeburg, 19.5; Danzig, 19.2, doubtless owing to their unfavourable proximity to the war area; while seven towns showed a figure below 12—viz., Hanover, Dresden, Frankfurt-on-Main, Düsseldorf, Hamburg, Stuttgart, and Bremen.

Issue of Food Certificates to Invalids.

The Berlin correspondent of the *Münchener Medizinische Wochenschrift* (No. 39) describes the recent experience with the issue of food certificates to invalids in Berlin. The intention was, where food-stuffs in general were short, to prevent patients from suffering. A schema had been drawn up, to be filled in by the medical attendant, giving in addition to personal details, diagnosis, complications and duration of the illness, the harm which might be expected to follow from not obtaining the particular nourishment (milk, eggs, butter, meat, flour) and the period for which special nourishment was required. This schema was to be obtained by the patient from the dépôt for invalid food, and handed by him to his doctor to fill in, the latter posting it direct to the dépôt. In special cases an urgent mark could be made on the envelope. The plan was well thought out for the following reasons: (1) It did not oblige the doctor to disclose to the patient the existence of a serious illness; (2) the distribution was to be made in proportion to the available supply and the severity of the illness; and (3) any displeasure for refusal fell not on the certifying doctor but on an anonymous committee. But the plan pre-supposed intelligent coöperation on the part of the public, and this unfortunately did not occur. The first announcements had hardly appeared in the press when everyone discovered an illness or recollected one from which he might have suffered years before and for which a nourishing diet had been prescribed. It was quite remarkable, says the correspondent, how in the summer months, in which as a rule the average health was good, the sickness returns suddenly rose, and even consulting rooms which were normally empty became filled to overflowing. The task for

the Berlin doctors, he adds, became a highly laborious as well as an invidious one. Some 70,000 certificates were presented in central Berlin alone to be filled in. The correspondent concludes with the remark that it would have been simpler to give up the use of milk and butter altogether than to carry through the scheme.

Recent Work on MSS. of Hippocrates.

Notwithstanding the manner in which the energies of Germany must be absorbed by the war her classical scholars are still publishing the results of their researches, and this is especially the case with regard to ancient medical literature. During last year Messrs. Teubner, of Leipsic, produced two more important volumes of the great Corpus Medicorum Græcorum. The first was the work of a trio of editors, Herren H. Diels, who some years ago edited the papyrus manuscript known as the Iatrica in the British Museum, and J. Mewalt and J. Heeg. This volume contains Galeni in Hippocratis Prorrheticum I. Deomate Secundum Hippocratem. In Hippocratis Prognosticum. Freiderich Marx has been responsible for the other work, which is the first volume of Celsi A. Cornelii, and has one plate. In the philological journal, *Hermes*, several essays have appeared augmenting our knowledge of the Hippocratean corpus. One of these concerns the collection of fragments of his *περί ἐπιδουάδων*, which were discovered at Venice some years ago by Herr Helmreich. Seven of the best preserved of these are now published, together with their corresponding Latin paragraphs in Littré's edition of Hippocrates, where the whole Latin recension of the book is

printed. This Latin text is, however, such a poor one that some editors prefer to give for this work only the numerous Greek fragments known, making these from Venice a welcome addition. Herr Helmreich shows that the lost complete Greek text was still extant as late as the seventeenth century. Meanwhile, the Egyptian papyri are perpetually rendering up portions of this famed author, and the Italian School of Papyrology has just brought out its first volume of new classical literature which contains solely "*Hippocrate, Aforismi*," and so will increase our knowledge of the correct original text of this book.

The most important study of a work of Hippocrates is by Herr F. Jacoby, who endeavours to restore the original text of the *περί Ἀέρων, Ὑδάτων, Ὠρίων*. This he strives to achieve by eliminating what he believes to be early additions, and later interpolated marginal glosses which in time have been foisted into the true text. He also describes several errors arising from manuscript transmission. He shows that the original work almost certainly terminated at Chapter XXIV. This work has been added to by someone familiar with Scythia and Greece, and these additions were made before Aristotle's time, because he knew of them. The first half of the treatise, concerning diseases induced by various climates, and the second moiety, relating to the effects of climate upon racial characters, are both by the same author. Valuable notes concerning this frequently quoted work, which may be said to be the precursor of modern ideas of the influence of climate upon history, as to its utilisation from the time of Aristotle and Galen, complete this interesting study.

New Inventions.

A NEW SPLINT FOR FRACTURED HUMERUS.

THE splint here illustrated is designed for cases of compound fracture of the humerus, and is a modification of Middeldorpf's triangle. The drawback of the latter is that it does nothing to neutralise the pull of the deltoid muscle, and, secondly, that it has a marked tendency to slip obliquely on the body.

The material of the splint is perforated zinc sheeting with $\frac{1}{8}$ inch holes. The body-piece is in halves, with a wire rod to serve as a hinge; the removable hinge makes the splint more manageable in padding it and for storage. The edges are stiffened by soldering on wire. The body-piece is fastened by a broad leather strap and buckle, with a brace over each shoulder buckling to the anterior edges. The arm-piece is fixed horizontally by a short strut of copper tubing near the axilla (in the illustration this is concealed by a bandage), and a longer strut fixed just above the elbow, the lower ends of both being soldered to the side of the body-piece. The forearm-piece is fixed at rather less than a right angle to the latter by a third strut placed horizontally. The edges of both arm-pieces are stiffened by wire, and if the wire were turned medially at the wrist its ends could be soldered to the chest-piece and thus replace the copper strut. The wire edging of the arm-piece is turned downwards at the axilla and soldered to the chest-piece below the upper edge, giving additional rigidity. Beyond the elbow

this wire is prolonged in a square loop a foot long with a ring at its centre. Above the elbow a stirrup is fixed by strapping, and extension is obtained by a spring fixed to a ring in the stirrup and at the outer end to a threaded rod passed through the ring on the square loop and tightened by a thumbscrew. This spring can be replaced by a rubber cord or by bandages. The limb is merely bandaged on the splint.

In the case illustrated the wound is on the outer side of the arm. When a dressing is required on the inner side the only change necessary is to have a trap-door cut in the zinc of the arm-piece.

The advantages I claim for this splint are: (a) The deltoid is thrown out of action, since the arm is held so high and the elbow with the lower fragment is immobilised by the forearm-piece. (b) As the splint goes completely round the thorax it cannot tilt from the weight of the arm. (c) The spring allows extension to any degree thought necessary — the one illustrated can be tightened up to 10 pounds' resistance; it does away with the inconvenience of having a weight dangling and swaying over a pulley. (d) This splint weighs

2lb. 15 $\frac{1}{2}$ oz. without padding. The patient was able to be up the day after it was applied, a stage which had been impossible for him with any other apparatus used in his case.

The splint was made according to my instructions by the engineer of this hospital. For the photograph I am indebted to Sergeant Brailsford, R.A.M.C. I have to thank Lieutenant-Colonel Gilbert Barling, consulting surgeon, Southern Command, for permission to forward this note for publication.

JAMES RAE, M.A., M.D. Aberd.,
Resident Surgeon, 1st Birmingham War Hospital.

THE LANCET.

LONDON: SATURDAY, OCTOBER 28, 1916.

The Position of Practice under the Insurance Acts.

THE Conference of representatives of Local Medical and Panel Committees from all parts of Great Britain, which met on Thursday of last week, had a heavy agenda paper to get through, and it was only by severe economy of time and concentration on major points that the meeting was able to break up before midnight. Discussion chiefly centred around the draft agreement for 1917 with the Insurance Commissioners, the question of collective bargaining, and that of panel practice in munition areas. With regard to the new regulations in the 1917 agreement, the feeling was general that it was neither fair to the practitioners absent on active service, nor to their colleagues doing double duty at home, that substantial alterations should be made in the panel practitioners' agreement with the Commissioners. The only alterations which panel practitioners could accept were such as were actually due to war emergency. Two departments of practice were recognised by the Conference as dictated by emergency: one, the scheme of the Local Government Board for control of venereal diseases, a proposal which emerged complete and perfect from the depth of the Government bureau without foreknowledge on the part of the Insurance Commissioners; the other being the treatment of disabled sailors and soldiers invalided out of the Services. In the case of the former the Conference, after a very full discussion, found itself prepared to adopt, in the words of the new regulations, "such steps as are reasonably necessary to enable the patient to take full advantage" of medical services provided by a public authority, but decided to limit this acquiescence to the Local Government Board scheme for venereal diseases, and to considering, if necessary, any further schemes on their own merits when they should arise. The position of the panel practitioner remains, as heretofore, a secure one, in that no public authority of whatever kind is in a position to dictate to him his duties in regard to any local scheme. The practitioner is only required to take such steps as seem to him and his local medical committee reasonably necessary, being responsible in the final issue to the Insurance Commissioners.

With regard to the treatment of disabled sailors and soldiers, which seemed in the second year of the war likely to attain to prodigious dimensions, it is understood that strong pressure is being brought by the Central Medical War Committee, the Committee of Reference of the English Royal Colleges, and the Insurance Acts Committee of

the British Medical Association, upon the War Office to postpone the discharge from the Service of any disabled man until his treatment had been carried through so far as to render him as useful a citizen as he could become. In this way, when discharged, the disabled ex-Service man, although a damaged life, should no longer require the amount of constant medical supervision from his panel practitioner which by anticipation had given rise to wide apprehension. When the position had thus been made clear the Conference decided to accept alterations in terms of employment with regard to the two departments of practice specially affected by the war, and to do so not grudgingly but as a tithe of the war service which panel practitioners were prepared gladly to render to the country. Whereas in controlled businesses generally profits had risen in proportion to the work done, this was not the case with the medical profession, whose arrangement with the Insurance Commissioners was precisely on the same terms as in pre-war times. At the end of the war this patriotic action on the part of panel practitioners should receive proper acknowledgment by the Commissioners. Far from being unwilling to enter upon any new schemes and developments in regard to panel practice, the Conference definitely decided to adopt a constructive policy for its action after the war, and to call upon the Insurance Acts Committee to draft a model scheme for a complete medical service for insured persons.

The question of collective bargaining between the British Medical Association and the Insurance Commissioners was discussed, and the recommendation made that three months' notice should be given to the Insurance Acts Committee of the Association of any prospective alterations in the agreement for the coming year, the Committee in its turn handing down to the Panel Committees the propositions at the earliest moment at which this could be done without breach of confidence. It was agreed that Local Panel Committees must be left free to make their own special arrangements with the Local Insurance Committees, and that it was not desirable to enforce any stereotyped scheme upon them. The formation of a trades union to enforce the collective interests of the panel practitioners upon Insurance Committees did not command the assent of more than a few of the representatives. It was very generally felt that the relation in which the medical profession stood to the various branches of the Insurance Commission was one which enabled them to obtain all that the trades unions would be only too glad to obtain for themselves. Two recent cases in the law courts, in which disputes between the doctor and his Insurance Committee had been decided in favour of the doctor, served to show that there was a practicable appeal even against the State as employer.

The third matter claiming the attention of the Conference was the question of certain conditions of panel practice in munition areas. The subject was dealt with in our leading article last week, our anticipation being based on the Memorandum issued by the Insurance Commissioners after conference with the Insurance Acts Committee of the

British Medical Association. The situation here was greatly improved by the interchange of question and answer which took place at the Conference itself, when several of the Commissioners, including Sir ROBERT MORANT and Mr. J. ANDERSON, came to the Conference ready to answer questions of fact as they were put to them. This privilege was made full use of and the answers received were such as to dispel certain of the misunderstandings and misgivings felt by panel practitioners in regard to the collection and distribution of the funds of the Insurance Commission. It became clear to the Conference that any increase of the insurance funds in the munition areas could only be obtained at present by a corresponding diminution of the funds in other areas. The extent of munition areas grows, and in many where actual numbers on the panel have not become greater, the increase of disablement, as well as the shortage of medical men, make the conditions of all panel practice exceedingly responsible and arduous. The representatives of the munition areas felt themselves, therefore, scarcely justified in pressing for favoured consideration in these circumstances. At the same time the Commissioners admitted that if there was to be any large efflux of completely or partially disabled men from the services it would be equitable to modify the formula on which medical benefit was calculated, and this is, in fact, having the careful and immediate attention of the Commission. These were the more important points discussed at the Conference, the whole of whose varied deliberations were of intense interest. The prevailing note of the meeting was one of intention on the part of panel practitioners loyally to carry out their obligations to their constituencies in a time of grave difficulty and pressure.

Economy of Time in Civil Medical Practice.

WE hear from many parts of the country that practitioners are overworked to the verge of breakdown, and, in spite of every effort, are unable to meet the demands upon their time. We know of one county with a fair-sized county town and for the rest only large villages and rural districts, in which the remaining medical practitioners are so thinly spaced out that the position would seem untenable if any single one of them were to become incapacitated. We have met the secretary of a local Medical War Committee, instituted for a large urban district, who had come up to London expressly to make representations to the Central Medical War Committee that one particular panel practitioner could not be spared and must on no account be granted a commission. And we chronicled a week or two ago the position of another large urban district in which the strain on medical men was such that they had hardly time to break bread. These things may be exceptions and not real samples of a general state of affairs. We take that view. There is still a thin margin in the majority of places between what can just be

done and what cannot possibly be done, otherwise the following alternatives would be before us: either the number of civilian practitioners must be increased, or the amount of work they have to do must be diminished, or the method in which the work is done must be rearranged.

We may dismiss the first two of these alternatives. Medical men, unlike poets, are the outcome of education and are not born instinct with pathological wisdom; and the amount of work that they must do cannot be controlled, for they will always accept it as their duty to perform all that lies within their conceivable scope. But the third alternative, the rearrangement of the civil practitioners' work, so that greater economy of time and of effort is secured, appears to come within the range of practical endeavour, in which case there is nothing panicky in giving timely consideration to the way in which such economy could be effected. A little forethought now might save huge friction in a few months' time. The medical work of general practice varies in urgency. On the one hand are accidents, cases of infectious disease and of acute illness of various kinds. At the other extreme are the illnesses of neurasthenics and the duty calls to patients, who are prevented in many instances from becoming more seriously ill owing to the confidence which they feel in their medical advisers. This latter class of practice has been profoundly modified during the war. Not only have medical men been unable to find time to pay their less urgent visits, but the atmosphere of this country, now seriously at war, has been uncongenial to the development of imaginary or "functional" disabilities. War has proved the capable doctor for such patients and has prevented rather than cured their conditions. It is openly stated in Berlin that when more than half of the medical men were called away at the outbreak of war those that remained had less to do, and this was accounted for by the disappearance of minor and especially of "functional" ailments. In our country such complaints as migraine have diminished in a remarkable degree, and this alone has sensibly relieved the practitioner. But the war should not be depended upon to do all the necessary reforms, and there are many directions in which the conduct of civilian practice could be made far easier by organisation. It has been suggested that the insured patients should be required to pay an extra fee for every call made between the hours of 10 P.M. and 6 A.M.; the surest way to check the thoughtless is some reasonable fine commensurate with the unnecessary visits, and when the public understands the absolute necessity of safeguarding the doctors' time we have no doubt whatever that this view will be taken. We think, however, that it should be always optional for the medical man to exact or remit this extra fee, ensuring that it should only be paid when the call might either have been made earlier in the day or have been delayed until the following morning. This is an idea that might be developed, and in many other ways coöperation could be instituted among medical men, with added convenience to their patients and with a great saving of time and

trouble to themselves. But, unfortunately, most schemes whereby medical men can help each other through some rearrangement of work must be confined to urban districts; medical practice in the country presents little opportunity for flexibility.

Where the work cannot be diminished or the strain be relieved by any methods of give and take between medical men it becomes the imperative duty of every medical man to see that he does not become over-wrought in doing his duty. Where there is a prospect of relaxation ahead pressure of work may be tolerated for a while, but continued strain only too often leads to breakdown, and breakdown may, in the present depleted state of our professional ranks, result in the dislocation of the practice of a whole county. Much doubtless may be done by deputing the non-medical part of the work to those who can do it equally well—the arrangement of notes and letters and the dictation of correspondence are obvious instances. Concentration on the essential parts of practice is very necessary. There is a movement on foot in Canada, of which a paper by Dr. F. B. GILBRETH in the *Canadian Journal of Medicine and Surgery* for July, 1916, was an index, to investigate the hospital from the standpoint of efficiency by means of the same methods of study as have been applied to great industrial concerns. Dr. GILBRETH finds that although the experience and skill of the hospital officer are of a very high degree, there is much lost in the application of them to the patient by the inefficient, indirect, or complicated modes of transference. Something of this obtains in our civil medical practice, and the medical practitioner must be on his guard in these times, when there is not more than enough of his skill and experience to go round, to see that his efforts do not get used up unavailingly, or fail to reach his patients unimpaired.

Annotations.

"Ne quid nima."

PRACTICAL INSTRUCTION IN THE DIAGNOSIS AND TREATMENT OF VENEREAL DISEASES.

THE practitioner who wishes to keep abreast of the movement for radically dealing with venereal diseases will need some opportunity of practical instruction in their diagnosis and treatment unless he has already been in a favoured position in this respect. The instruction naturally divides itself into the methods of obtaining materials for diagnosis and the methods of administration of remedies when the diagnosis has been established. The taking of the materials is the smaller affair, but still of great importance. At institutions where it is done systematically the technique looks so simple that the onlooker may fail to appreciate the pitfalls which exist for the unwary. He must therefore lose no opportunity of practising the methods himself and of acquiring the "laboratory fingers" which are essential to success. To take a smear from the urethra for the detection of the gonococcus is not difficult. To procure a specimen of serum in a capillary tube from a suspected syphilitic sore demands a little care. When the report on this serum is negative the

obtaining of some juice from a lymphatic gland draining the suspect area is required, and in this manœuvre the prospect of success is much enhanced by the injection of one or two cubic centimetres of saline into the gland, which is massaged before the sample is withdrawn. Practical methods such as these must be seen to be appreciated, as well as the venipuncture and lumbar puncture to obtain the fluids for the Wassermann reaction. At this stage, the materials being obtained and sent up for report, the practitioner can, if he choose, leave the matter. But if he does so he will never share in Schaudinn's joy when he first saw the *Spirochæta pallida*. As may be read in Neisser's obituary notice in another column, this great discovery, to which he had approached so close himself, was made in his laboratory during his absence in Java. Finally, the technique of administration, both intravenous and intramuscular, of remedies in syphilis requires little apparatus or technical skill, but rather the strict observance of details, many of which can only be learnt by practical experience, and rapidly learnt in places where the methods are practised in routine on a large scale. Under these conditions the intramuscular injection of mercury almost suggests a very well-ordered circus, and the administration of 50 intravenous doses of salvarsan or luargol can be covered in an hour and a half in a room large enough for three recumbent patients. For the neosalvarsan, which is at present the only colloid arsenic preparation which can wisely be administered intramuscularly, we are still unfortunately dependent upon captured supplies. In large centres where arrangements for treatment already exist the practitioner can—as we have noted is the case in London—obtain his practical instruction before the clinics under the new scheme are instituted, and he will be well advised to do so. The chairman of the London County Council stated at the recent Mansion House meeting that the complete scheme for London and the Home Counties should come into force early in the new year. In other centres, where building, equipment, and pathologist must first be found, some delay is inevitable, but should, in the interests of everyone, be made as short as possible. We welcome, therefore, the early appearance of a scheme such as that of the borough of Portsmouth, and shall hope to give from week to week the essentials of this and other schemes in so far as they include novel methods and arrangements.

ANÆSTHETICS IN MILITARY HOSPITALS.

VARIOUS correspondents have addressed us lately upon the choice of anæsthetics and of methods by which they shall be administered in military hospitals. There are several reasons why the question cannot be answered exactly along the lines of ordinary practice. The principles according to which anæsthetics and methods are selected remain the same as in civilian hospital practice, but the personnel of the patients introduces new features. Thus, to some extent in base hospitals abroad, and to a very large extent in the military hospitals here, the patients are young men in first-rate condition. They are, from the anæsthetist's point of view, difficult subjects because of their muscularity and fitness. On the other hand, large numbers of the patients in the military hospitals nearer the fighting line are men in a condition of shock, of exhaustion, or of serious sepsis. To anæsthetise such patients is never difficult; the difficulty is, on the other hand, not to add to their damage. The contrast between the two classes may be stated

broadly as being that the first are anæsthetised with difficulty but recover with ease; the second are easily anæsthetised but much more likely to suffer afterwards. It is particularly in the case of the latter, men who are bodily and perhaps also mentally greatly depressed or suffering from septic poisoning, that some of the newer methods of anæsthesia are very valuable. It is in these cases that intravenous administration of ether or of alcohol, or prolonged administration of nitrous oxide combined with preliminary morphia and atropine, are often to be preferred to simpler and older methods. In such cases chloroform is particularly undesirable, as Colonel J. Campbell points out in our issue of Sept. 30th, and we would add a caveat against the adoption of this anæsthetic as a routine amongst the healthy patients of the other class alluded to. It would be a pity if the comparative convenience of this agent were allowed to weigh against its undoubtedly easier association with danger in the selection of a routine anæsthetic. Where the administrators are men of wide experience the anæsthetic and the method become of less importance. As one of our correspondents writes, "it is not the anæsthetic, it is the way it is given," and this is of course very true; but in making suggestions that may be widely followed we must bear in mind that many of those who may follow them are bound, in the nature of the case, to be men to whom anæsthetic work has not hitherto fallen in large quantity. For them the first essential is to secure safety, and for that purpose their mainstay must be ether. It is probably the comparative tediousness of induction by the open method in the case of strong healthy men, and the difficulty often of maintaining complete relaxation, that turn the commencing anæsthetist from ether. Here we may draw attention to the use of ethyl chloride in the course of induction, and support the suggestion of one of our correspondents that this agent might with advantage be much more frequently employed. Moreover, in induction in strong subjects the administrator need not hold himself academically bound to a pure open method; such patients will suffer no inconvenience, and everybody else concerned will be greatly relieved, by a brief use of the wide-bore Clover.

A NEW FORM OF X RAY TUBE.

In a supplement to the *Scientific American* there is a description of a new form of X ray tube that may prove to be an improvement on that introduced by Mr. Coolidge. The essentially new feature is that the filament producing the necessary electrons, instead of being in the centre of the cathode itself, is mounted in an accessory bulb placed immediately behind the cathode, the latter being provided with a central hole through which the electrons from the filament are made to pass. This hole being a small one the electrons fall on the anticathode in a correspondingly small dense bundle giving a sharp focal point from which the X rays emerge, and an almost complete freedom from stray radiations, which are more or less common to all tubes and a constant source of danger to all X ray workers. If the claims made for this Lilienfeld tube are borne out in practice there is no doubt that it will be a considerable improvement on anything that has been available up to the present, though the necessity for an auxiliary current to heat the filament still remains as in the Coolidge tube. We gather that the idea is of German origin, and further developments may not occur during the continuance of the war.

SOME ASPECTS OF THE THROAT AND NASOPHARYNX IN THEIR RELATION TO GENERAL MEDICINE.

In the presidential address delivered by Dr. Arthur Saunders to the West London Medico-Chirurgical Society on Oct. 6th, the throat was considered as a site of systemic general infection. He drew attention to some of the forms of catarrhal inflammation of the nose and throat, which, though at first mild in degree, might constitute if neglected a direct danger to health—nay, even to life—as well as to some of the more severe infections originating in those regions. But, even apart from such severe infection, acute inflammation of the adenoid tissue of the naso-pharynx is far from uncommon, especially in children, producing high fever and perhaps rigors, severe frontal and occipital headache, and even collapse. In the absence of any complaint of the throat the true nature of the condition may easily be overlooked, but a careful examination of the pharynx and naso-pharynx will usually disclose the cause of the symptoms. The lymphoid tissue of tonsils and adenoids which have undergone chronic irritation from infection is left damaged and impaired to resist a future invasion. Moreover, a morbid condition of the mucous membrane of the fauces affords a more suitable soil for the development of many infectious diseases. Dr. Saunders especially referred to diseases which, constantly occurring in this country as sporadic cases, occasionally assume a virulence and infectiousness which lead to their distribution in epidemic form such as cerebro-spinal fever and acute poliomyelitis. Investigations as to the prevalence of "carriers" in the distribution of cerebro-spinal fever, especially when the disease is epidemic, have brought out some remarkable facts. It would appear that at least in epidemic times the number of carriers who do not themselves become infected with the disease is very large. There appear to be grounds for the belief that chronic catarrhal conditions of the naso-pharynx may be associated with the persistence of the "carrier" condition. Dr. Saunders is of the opinion that this last sentence contains the expression of a more general truth than is suspected, and that close investigation and a wider experience will show that catarrh of the mucous membrane *does*—the italics are Dr. Saunders' and we adopt them—favour the reception, persistence, and multiplication, with consequent increased opportunity and incidence of infection, in the case of cerebro-spinal fever, as in diphtheria and probably many other diseases. Dr. Saunders is of the opinion in acute poliomyelitis again there is little doubt that the throat and naso-pharynx are one of the chief sites of entrance of the virus into the system. From what has been said it follows that by keeping the mucous lining of the throat, the naso-pharynx, and the mouth generally, healthy much can be done in the prevention of disease; and by prompt attention to local lesions and unhealthy conditions much can be done for the prevention of greater ills. Dr. Saunders urges fresh air and well-ventilated rooms, as well as the possession of what one may call a well-ventilated pharynx as important factors in the preservation of health. To these ends enlarged tonsils and adenoids undoubtedly should be removed in all cases where symptoms of obstruction, whether faucial, naso-pharyngeal, or Eustachian, are being produced. Tonsils, if diseased, although not obviously enlarged, especially if the infra-maxillary glands are chronically

enlarged, or if frequently the site of acute inflammatory attacks, should be removed. As infective organisms are frequently to be found in the deepest portions of the gland the method of removal should be complete and by enucleation.

BORIC ACID IN CREAM.

THE amending Order in regard to milk and cream regulations issued last week by the Local Government Board places the question of the use of boric acid as a preservative of cream on a definite basis. The regulations hitherto permitted the use of boric acid in cream so long as the presence of this preservative was declared, but there was no limit laid down as to the quantity of boric acid added. The amending Order, while still requiring a "declaratory label," does not permit the use of more than 0.4 per cent. boric acid by weight of the preserved cream. The Order also requires that the label on the cream so preserved shall bear the words "not suitable for infants or invalids." In the case of hydrogen peroxide being used as the preservative, the label is required to be drawn up in the same terms, but then no statement is demanded as to the quantity of the peroxide present.

THE OUTBREAK OF ACUTE POLIOMYELITIS IN NEW YORK.

UP to the last available date of record there have been in New York City and the adjacent States of New York, Connecticut, Massachusetts, New Jersey, and Pennsylvania the following number of cases and deaths:—

| | Cases. | Deaths. |
|--|--------|---------------|
| New York City (Sept. 30th) | 9,029 | 2286 |
| New York State, exclusive of New York City (Sept. 14th) | 2,785 | 318 |
| Connecticut (Sept. 18th) | 677 | Not reported. |
| Massachusetts (Sept. 19th) | 671 | 95 |
| New Jersey (Sept. 19th) | 3,495 | 775 |
| Pennsylvania (Sept. 20th) | 1,278 | 313 |
| | 17,935 | 3787 |

Amid all the ignorance as to the means of distribution of the virus, and the inconsistency of experience in different epidemics, climates, and continents, two facts in relation to medical experience in New York City stand out with striking clearness. They have been pointed out to us by Dr. Haven Emerson, Commissioner for the Department of Health in New York, who writes as follows:—

1. We have had no case among the 30,000 children in institutions for orphans, &c., in New York City. By institutions I do not mean hospitals or such places as day-nurseries, but the permanent homes of children outside of families. These institutions are under the supervision of the Department of Health, and we excluded all visitors at the beginning of the epidemic and maintained as usual the two weeks' quarantine for all children on admission—i.e., two weeks for isolation and observation before admission to the general living rooms, dormitories, and dining rooms. These institutions have the same water, pasteurised milk, and the same food as other children. They are no more protected against flies and mosquitoes, but are probably less afflicted with fleas and bed-bugs than many poor homes. Not a single case up to date, and the children are of all the most susceptible ages.

2. No case has been found on Barren Island, an island in Jamaica Bay, Borough of Brooklyn, where 1300 people live, and upward of 350 children. All city garbage is rendered on the island, also all dead animals are reduced to their commercial elements. There is no general water-supply; the water is from shallow wells. No sewerage, no roads, no local garbage removal, little good sanitation in or out of homes, abundant flies and mosquitoes, and an ignorant population of low-grade Poles, Italians, and coloured people working in

and about the rendering plants. They are geographically and socially isolated from all but the rarest contact with the rest of the city.

It is obvious from the experience in New York and elsewhere that many of the facts upon which an intelligent and logical sanitary control of acute poliomyelitis can be based are still to seek.

PETECHIAL ERUPTIONS IN CAMP FEVERS.

DURING the present campaign attention has been drawn to the frequency with which signs of cutaneous hæmorrhage are met with in troops at the front during various infectious diseases, especially typhoid fever, giving rise at first to serious doubt as to the differential diagnosis from cases of typhus. Last August, while inspecting a sanitary station where troops from various sectors were concentrated, Dr. G. d'Ormea and Dr. M. Segale¹ found five cases with symptoms of severe typhoid and a diffuse petechial eruption which appeared between the fourth and fifth day from the apparent onset of the disease. These subjects had been inoculated against typhoid. Blood-cultures were made in three of these patients: in one the organism of paratyphoid B was isolated, in another typical colonies of *B. typhosus*; the third culture gave a negative result, probably owing to lack of sufficient material. In two of these cases positive evidence of typhoid enteritis at the middle of the second week was found. The same observers, working in another part of the front, noticed, in a large number of necropsies, frequent manifestations of cutaneous hæmorrhages more or less extensive in patients dying not later than between the tenth and fifteenth day of a disease which clinically ran the course of a continuous or subcontinuous fever. The necropsies and bacteriological investigations in these cases confirmed the presence of typhoid, in a large number with typical forms of Eberth's bacillus and sometimes with that of paratyphoid B. These cases, although not very numerous, were sufficiently striking, since they led to the suspicion of petechial typhus, and were, on the contrary, ordinary typhoid, often severe, in both inoculated and non-inoculated or cases of paratyphoid B. Petechial eruptions in typhoid are of extreme rarity in ordinary civil practice, and their occurrence with relative frequency in camps leads to the supposition that there are certain conditions inherent to the surroundings which favour their occurrence, the most probable explanation being that they are connected with hæmovascular instability consequent on a defective régime to which soldiers are exposed, without excluding as contributory causes over-exertion and nervous exhaustion. Widal in 1915 insisted on the absolute necessity of serological examination before diagnosing petechial typhus in order to exclude error with regard to typhoid, and Dr. d'Ormea and Dr. Segale emphasise the same point. They also draw attention to the analogy between these petechial forms of typhoid and the cases of diarrhoea and trench nephritis as having some probable relation to the diet of soldiers at the front, which contains an excess of animal food in proportion to cooked or raw vegetables.

THE autumn session of the General Council of Medical Education and Registration will commence at 2 P.M. on Tuesday, Nov. 28th next, when the President, Sir Donald MacAlister, K.C.B., M.D., will take the chair.

MEDICINE AND THE LAW.

A Serious Baby-farming Case.

AT the recent session of the Central Criminal Court a woman named Richardson was sentenced to five years' penal servitude, after pleading guilty to charges of theft and of obtaining by false pretences sums of money from three persons who had entrusted infants to her care. The practice of the prisoner in connexion with baby-farming was to receive a substantial sum upon the undertaking that she would take care of a child, and then to get rid of the infant to someone else with little or no cost to herself. In one of the cases before the court she had received £8 from the mother, an unmarried woman, and on the same day had left the baby with another woman asking her to look after it for an hour or two, but had never returned for it. In another instance a charge of manslaughter had been brought against two women with whom she left a child which soon afterwards died, but the women were acquitted. In the third case the infant had been received by the prisoner, who had agreed to look after it, but the child had disappeared and she had refused to give any information by which it could be traced. The attention which at the present time is being directed to the importance of the preservation of the lives of infants lends additional interest to such cases, and the police are to be congratulated upon having put a stop to Mrs. Richardson's activities for some time.

The Property in a Prescription.

Points of considerable interest to the medical profession were raised in a recent action brought in the Honiton county court against Messrs. Hinton and Lake, a firm of druggists at Sidmouth, by Mr. H. Le Brasseur. The plaintiff's wife consulted Mr. C. W. Grant-Wilson, who gave her a prescription which she took to the defendants to be made up. The prescription was not returned to her, and her husband asked that it should be, but his request was refused, the defendants saying that they had undertaken, at the request of Mr. Grant-Wilson, not to return his prescriptions to patients unless he expressly authorised them to do so. In the case in question Mr. Grant-Wilson refused to allow the prescription to be returned, but afterwards enclosed a copy of it to the plaintiff when sending him a receipt. The plaintiff claimed the return of the prescription, or 15s. as its cost. Mr. Grant-Wilson, in his evidence, stated that the course adopted by him with regard to prescriptions was taken for the protection of the public, and he illustrated the danger of allowing prescriptions to be retained by the patient by saying that not infrequently a medicine ordered for an adult was given, without any medical man being consulted, to an infant. He had requested druggists to inform him whenever a patient asked for the return of a prescription, and he made a practice of writing on prescriptions which might properly be handed back without question the words, "Return to patient." The solicitor for the defendants pointed out that the prescription was of no value to them and that they were only contesting the case on the question of principle and in order to keep faith with the medical profession and with Mr. Grant-Wilson. His honour Judge Lindley held that no property in the document had passed to the plaintiff, as the prescription had only been handed to the patient in order that it might be conveyed by her to the druggists to be made up instead of the medical man himself sending it. The action therefore failed and the claim was dismissed with costs.

R. v. Burdee.

This case, in which, as already noted in THE LANCET of Sept. 16th, p. 531, an unqualified person, Henry Burdee by name, was sentenced to 12 months' hard labour for manslaughter after having "medically" treated a woman who died in consequence, came before the Court of Criminal Appeal recently. It will be remembered that Burdee applied a so-called "cold-water cure" combined with starvation to his unfortunate patient without having made any examination to assure himself that she was fit to undergo such an ordeal, and that the medical evidence showed that death was due to disease of the heart accelerated by lack of food. After hearing argument to the effect that there was no evidence of such gross negligence or criminal inattention

as would justify a conviction for manslaughter, the court reduced the sentence to 12 months' imprisonment in the second division, but held that there was ample evidence to support the conviction. Mr. Justice Darling in delivering judgment said that if a person, whether a qualified medical practitioner or not, professed to deal with the life or health of any person, he was bound to have competent skill to perform the task. The convict held himself out as qualified to perform certain work, and he was bound to treat his patients with care and attention. The appellant had no medical knowledge and the evidence showed that he was ignorant of anatomy. He had a stereotyped treatment which he advised without any consideration of the patient's condition. The conviction must therefore stand. The conclusion thus arrived at must be regarded as satisfactory, and the case is likely to be cited upon similar occasions for some time to come when a quack undertakes the treatment of a patient who dies. It is to be regretted that the negligence of an unqualified person treating disease is not likely to become the subject of a criminal charge under this precedent except in those cases in which death may be the result of his attentions. It is not for the sake of the medical profession that better protection is required, but for the sake of the public.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal College of Physicians of Ireland.

THE annual meeting of the President and Fellows of the Royal College of Physicians of Ireland was held in the College Hall, Kildare-street, Dublin, on St. Luke's Day (Oct. 18th). The following elections were made:—President: Dr. Joseph O'Carroll. Vice-President: Dr. H. T. Bewley. Censors: Dr. Bewley, Dr. Martin Dempsey, Dr. W. A. Winter, and Dr. B. Solomons. Examiners for the Licence to practise midwifery: Dr. E. Hastings Tweedy and Dr. Spencer Sheill. Additional Examiners to take the place of an absent Censor or Examiner: Medicine, Dr. W. Boxwell; Medical Jurisprudence and Hygiene, Dr. Falkiner; Midwifery, Dr. Spencer Sheill. Supplemental Examiners under the Conjoint Examination Scheme: Biology, Dr. Nesbitt; Chemistry, Dr. Ninian Falkiner; Physics, Dr. W. G. Harvey; Physiology, Dr. H. C. Earl; Anatomy, Dr. R. J. Rowlette; Pathology, Major F. C. Purser; Pharmacy, Materia Medica, and Therapeutics, Dr. George Peacocke; Medicine, Professor T. G. Moorhead. Examiners for the Conjoint Diploma in Public Health: Hygiene, Dr. S. T. Gordon; Bacteriology, Dr. Earl; Sanitary Law and Vital Statistics, Dr. Ninian Falkiner; Meteorology, Dr. J. A. Matson. Examiners for the Membership: Clinical Medicine, Dr. Bewley and Dr. Dempsey; Practice of Medicine, Dr. Winter and Dr. Nesbitt; Pathology, Dr. Earl and Dr. O'Sullivan; Obstetrics and Gynaecology, Sir Andrew Horne and Dr. Hastings Tweedy. Representative of the College on the General Medical Council: Sir John W. Moore. Representatives of the College on the Committee of Management: Dr. Walter G. Smith, Sir John Moore, and Dr. T. Percy C. Kirkpatrick. Treasurer: Dr. Bewley. Registrar: Dr. Kirkpatrick. Librarian: Mr. Robert Phelps.

The Royal Victoria Hospital, Belfast, and the War.

The inaugural address of the present session was delivered on Oct. 19th, in the hall of the King Edward VII. Memorial, to the students attending the clinics of the Royal Victoria Hospital by Professor J. A. Lindsay, who delivered a wise and spirited homily on the broad relations of medical men to the sick. At the close of the address the chairman of the medical staff of the Royal Victoria Hospital, Sir John Byers, referred to the part that the institution was taking in the present crisis. One hundred of the beds, he said, were being retained for wounded soldiers and officers. Six of the members of the visiting and auxiliary staff and 180 of their former students (many of them old house surgeons and house physicians) were now on military service, as well as three of the sisters and 17 of the nurses. Eight of the old students had been killed in action or had died when on service. Thirty-two distinctions had been conferred on members of the staff and former students. Of these, 18 were mentioned in despatches, 9 had obtained the Military Cross, 2 the D.S.O., 1 the C.M.G., 1 the C.B., and 1 (Major

J. A. Sinton, I.M.S.) the Victoria Cross. Among those mentioned in despatches was Lieutenant-Colonel Sir David Semple, who, since 1913, had been Director-General of the Public Health Department of Egypt. Miss Bostock, the lady superintendent of the Royal Victoria Hospital, has been decorated by the King with the Red Cross (First Class).

Irish Doctors of Military Age.

At a meeting of the Omagh guardians, held on Oct. 21st, a letter was received from the Local Government Board, to the effect that, whilst adhering to the principle already announced, not to sanction a doctor of military age to any position in the Poor-law medical service, so long as a practitioner of non-medical age was available and otherwise suitable for the duty, they had no option but to approve of the temporary appointment of Dr. D. F. Murnaghan in the Omagh No. 1 Dispensary District, as they were not in a position to suggest an alternative arrangement suitable to the exigencies of the case. They suggested that as the term of employment might be prolonged the guardians should arrange the remuneration at the fixed salaries attached to the medical officership, instead of £4 4s. weekly. The Board also signified (for the same reasons) their approval to the temporary appointment of Dr. Murnaghan as workhouse medical officer.

Oct. 23rd.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Preventive Treatment of Post-operative Peritonitis.

To prevent the occurrence of peritonitis after laparotomy in cases where septic foci are present M. Chaton employs a film of camphorated oil. His method is as follows. After opening the belly a certain quantity of camphorated oil is poured in and the patient placed in the position required by the operation; the incision is closed and a dozen inspirations allowed, after which the operative compresses are applied; these absorb any excess of oily fluid. The oil obstructs the lymphatic channels of absorption, hinders the adhesion of loops of gut, and permits of prolonged drainage, besides playing the part of a cardiac tonic. Ampoules of 25 and of 10 c.c. are employed, and 300 c.c. of a 1 per cent. solution of camphor can be used without inconvenience. The author has obtained encouraging results by this method.

Prevention of Tetanus by the use of Antitetanic Serum.

Before the Academy of Medicine M. Netter has laid stress on the services of antitetanic serum, recalling the excellent results obtained from its use in the United States of America. On the occasion of the jollifications which take place each year on the national fête in 1903 the number of wounded citizens amounted to 4449, and of these 417 acquired tetanus. Six years later in 1909, after the practice of antitetanic serum injection had been introduced, a larger total of casualties included only 150 cases of tetanus. During subsequent years the number of cases has continued to diminish, reaching zero this year. M. Capitan, in continuing the discussion, emphasised the advantage of high dosage. He considers that in severe infected wounds, or when a projectile remains embedded in the tissues, the usual preventive dose of 20 c.c. should be increased to 30 or 40 c.c., to be repeated in case of need.

A New Treatment for Gunshot Wounds.

Professor Pierre Duval, at present on active service, recently showed before the Society of Surgery a series of 12 men severely wounded on the Somme front. Although the wounds were such usually intractable ones as compound fracture of the knee, they had recovered in two or three weeks without fever, drainage, ankylosis, or plaster bandage, the healing of the wounds even taking place by first intention. These results, which much impressed his audience, were obtained by methods in complete contrast to those usually practised. With the shortest possible delay after the infliction of the wound M. Duval opens up freely the gunshot track, as well as all other tracks, cleans the surface with ether, and deliberately excises the whole wound, cutting for an extent of 1 or 2 cm. into healthy tissue. Renouncing, in short, antiseptics and any attempt to destroy the imported microbes, he treats the whole neighbourhood of the infected injury as he would a malignant tumour by simply removing

it. After finding himself in entirely healthy tissue he sutures the synovial membrane, reunites the ligaments, and brings together the edges of the wound without drainage. The results have been surprising; he has been able to dispense with bandages, irrigation, and the drainage of prolonged discharge. At the same time, the rapid return of function is very striking. One of the wounded men, who was already walking with the aid of a stick, had been hit on the knee three weeks before by a fragment of shell which penetrated the knee-joint, a type of wound which up till now has generally resulted in ankylosis when death did not supervene from a rapid infection. The method is one the wider application of which appears likely to modify considerably our treatment of gunshot wounds.

Treatment of Severe Burns.

M. Kirmisson also showed before the Society of Surgery four patients of M. Barthe de Sandfort treated with ambrine¹ for severe burns of the face, trunk, and upper limbs. The burns were seen to be supple and with little or no tendency to contraction. The mode of dressing employed by M. de Sandfort, thanks to which M. Michaux also obtained equally good results, had, above all, the advantage of suppressing or greatly diminishing pain and expediting cicatrization. M. Toussaint also reported excellent results with ambrine in the severe burns under his care.

A Medical Victim of the X Rays.

Dr. Ménard, the well-known director of the electro-radiologic service of the Hôpital Cochin, has just had his index finger removed, another victim amongst workers in the cause of the advancement of radiology and of the care of the wounded. Some little time before the war he had already lost the index finger of his right hand. M. Malvy, the Home Secretary, has just decorated him with the Legion of Honour, and by a decision dated Oct. 6th the War Minister has awarded him the gold medal of preventive medicine.

CANADA.

(FROM OUR OWN CORRESPONDENTS.)

Surgical Hospitals for Canada.

THE Canadian Hospitals Commission has now organised a system for convalescent returned soldiers. It is still, however, considered advisable for the Canadian Government, acting through the Commission, to establish surgical hospitals right across Canada. These hospitals will receive soldiers able to take the voyage across the Atlantic and relieve the pressure in England. Many who are to undergo operation could, it is thought, be safely transported here to receive the necessary surgical treatment, and there are yet many skilled surgeons in Canada at the cities of Halifax, St. John, Montreal, Ottawa, Toronto, Winnipeg, Vancouver, and Victoria, who would only be too willing to do their part in military hospitals established at home for this purpose. When this is included in the programme of the Hospitals Commission, Canada will be in a splendid position to deal with all classes of returned soldiers.

Acute Poliomyelitis in Ontario.

Infantile paralysis is spreading in Ontario. The provincial health authorities are considerably concerned, and are contemplating steps to deal more rigorously with the situation. It may be found necessary to close the kindergarten schools and the moving-picture shows to children under 14 years of age. During the month of September there were 49 cases of the disease in the province of Ontario and 5 deaths, while in the month of August there were 44 cases and 5 deaths. In July the record was 20 cases and 3 deaths. The epidemic seems to be more or less general and covers different parts of the province. There was one case in a man 50 years of age. Dr. Roberts, the medical officer of health for Hamilton, where there have been at least a dozen cases, has recently issued an order that children shall not be admitted to any theatres in that city.

Treatment of Diphtheria in the Alexandra Hospital, Montreal.

It is ten years since this hospital was opened in Montreal, and all cases of diphtheria are placed directly under the

¹ See THE LANCET, 1916, vol. 1, p. 1187.

care of the medical superintendent, who is selected after receiving special training in infectious diseases hospitals in the large cities of America. But hospital treatment of diphtheria is not obligatory in Montreal. Dr. H. B. Cushing and Dr. E. V. Murphy have reported¹ upon 2208 patients with diphtheria treated in the hospital during the ten years of its existence. Five per cent. gave a history of previous attacks of diphtheria. Two per cent. occurred in the first year of life, 5 per cent. in the third year, 9 per cent. in the fourth year, 10 per cent. in the fifth year, and then a steady diminution in the percentage cases until the fifteenth year, after which only scattered cases occurred up to the sixtieth year. Among the attendants 51 cases of diphtheria occurred; only 30 of all other infectious diseases altogether. There were no fatalities in the 51 attendants with the disease, and no attempt was made to immunise the attendants. In all cases the diagnosis was based on routine cultures taken on admission. Diphtheria causes about 200 deaths each year in Montreal, and it is still the most fatal contagious disease in the city. Before 1900 the mortality in all published statistics was from 30 to 40 per cent.; since the use of antitoxin has become general it has sunk to 10 per cent., but it is rarely, even in institutions, below this. In the Alexandra Hospital in ten years there have been 166 deaths, or 7½ per cent., making no deduction for those dying immediately on admission. In the year 1915 there were 417 cases and 21 deaths, a mortality of 5 per cent. The laryngeal cases were as usual the most fatal. There were 205 cases where intubation or tracheotomy was necessary, and of these 55 died. In 1915 there were 31 cases of intubation with 5 deaths. Apart from the laryngeal cases the septic and the hemorrhagic cases raised the mortality. Of these there were 12 cases, and all died. Cardiac disturbance, noted in the total cases in 10 years, amounted to 109 cases; albuminuria occurred in 342 cases. Antitoxin is regarded as an absolute specific for the disease, the only cases lost being those admitted too late for treatment or those with some fatal complication. As to any bad results of antitoxin, no record of true anaphylactic shock or death occurred. The routine treatment is to give one large dose on admission, and repeat only in serious cases, or if the membrane extends subsequently, or if there is no improvement in 24 hours. In 1000 consecutive cases only one dose was given in 70 per cent., while 30 per cent. required one or more additional doses. Usually 3000 to 4000 units are given in mild and early cases; 6000 to 8000 units in more serious cases or when the disease has lasted over 48 hours; 10,000 to 12,000 units in all very serious cases. In 1000 cases the average total dose was between 6000 and 7000 units. The low mortality has apparently justified these doses. One essential in the treatment is to preserve the strength of the patient. Dobell's solution is used to cleanse the throat. Absolute rest in bed in all cases is insisted on, and the diet is milk and then soft foods. Ice-collars are used for adenitis, two hours on and two hours off. After two weeks discharge cultures are taken and the patients leave after two negative cultures. The average stay in the hospital was 21 days.

Tuberculosis among Canadian Troops.

A conference was held in Ottawa, Canada, under the supervision of the Canadian Hospitals Commission, to deal with the question of tuberculosis amongst Canadian troops. There are nearly 400 tuberculous soldiers in the hospitals set apart for these cases, and of this number about one-half have been overseas. Dr. Alfred Thompson, M.P. (Yukon), presided at the conference, the expert physicians summoned being Dr. A. R. Baldwin, Saranac Lake, N.Y.; Dr. Charles D. Parfitt, superintendent of Calydor Sanatorium, Muskoka; Dr. J. H. Elliott, Toronto; and Dr. J. R. Byres, Ste Agathe des Monts, Quebec.

Toronto, Oct. 13th.

¹ For full report see the September issue of the Canadian Medical Association Journal.

INSANITARY CONDITIONS IN LINCOLNSHIRE.—At a meeting last week of the Branston rural district council at Lincoln it was stated that in parts of Boultham parish the contents of middens had not been removed for six months, and that school children were suffering in health from the omission. The surveyor stated that the condition had arisen through shortage of labour.

THE SERVICES.

ROYAL NAVAL MEDICAL SERVICE.

To be temporary Surgeons: C. N. Ratcliffe, G. P. Burr, W. B. Heywood-Waddington, C. McDonald, and C. H. Terry. The following appointments have been notified:—Temporary Surgeons: J. F. M. Campbell to *Imperieuse*; C. P. Barber to *Pembroke*, additional, for Chatham Hospital; J. Brumwell, J. J. Carroll, and G. E. S. Ward to the *Victory*, additional, for Haslar Hospital; and H. E. Hall to *Vivid*, additional, for Plymouth Hospital.

ROYAL NAVAL VOLUNTEER RESERVE.

To be Surgeon: F. P. Nicholas.

ARMY MEDICAL SERVICE.

TERRITORIAL FORCE.

Lieutenant-Colonel (temporary Colonel) G. F. Gubbin relinquishes his temporary rank on vacating the appointment of Assistant Director of Medical Services.

ROYAL ARMY MEDICAL CORPS.

Major J. D. Richmond to be temporary Lieutenant-Colonel while in command of a Field Ambulance.

Temp. Lieut. J. B. Stephens to be temporary Major.

To be temporary Captains: J. M. Browne, H. K. Groff, C.A.M.C. (late Lieut., R.A.M.C.), E. R. Hunt, J. D. Barris, A. R. Munroe, C.A.M.C. (late Lieut., R.A.M.C.), and Temp. Lieuts. H. G. Kilner, C. R. M. Patison, W. Martin, V. T. W. Eagles, H. Stokes, J. R. B. Dobson, G. C. Ramsay, J. T. MacKenzie, R. M. Hume, D. C. McCabe-Dallas, J. Henderson, J. F. Adamson, S. A. McSwiney, J. Crowley, P. T. T. Macdonald, J. G. Cronyn, J. N. Macdonald, W. B. Thompson, C. R. B. Eyre, J. Donald, J. C. Bawden, C. H. W. Page, J. E. Rees, A. C. Falkiner, M. Polson, H. H. Stones, L. W. Crowe, W. H. Anderson, J. P. E. Henery, T. E. Mulvany, A. F. G. Kerr, E. H. Sheehan, and D. Welsh.

To be temporary Lieutenants: J. H. Thornley, W. J. Morrish, A. B. Ferguson, E. Howe, J. Langwill, G. E. Kinnersley, G. J. Farie, C. C. Kerby, T. W. Walker, L. Leslie, W. T. Morton, F. H. P. Wills, E. F. R. Alford, G. de Bec Turtle, A. Spong, T. M. Bellew, G. E. Macvie, J. R. Burnett, W. F. Addey, J. G. Shanklin, A. J. Hutton, G. M. B. Liddle, H. S. Jones, R. Franklin, A. M. Barlow, W. B. Harris, A. A. Murison, R. C. H. Francis, S. F. Cheesman, H. W. Ogle-Skan, J. E. Frere, N. Purcell, R. H. Beardsley, R. McAllister, G. W. Harrison, J. H. P. Vivian, J. G. G. Pigott, H. E. Girdlestone, J. Naylor, Surg.-Lieut. R. G. Griffin (Assam Valley Light Horse), W. G. McAfee, A. S. Ransome, H. G. Westropp, C. E. H. Paley, J. D. Pearson, H. P. W. Lincoln, J. Whitehead, M. Jenkins, L. G. Carment, E. R. Thompson, D. L. Carmichael, R. Brookes, L. Cairns, J. Paterson, M. J. Loftus, D. MacKinnon, E. T. Jameson, L. B. Fannin, W. J. Thomas, and G. A. Crowe.

Temporary Captains relinquishing their commissions: R. M. Allan, E. C. Lindsay, E. C. Black, H. A. Lunn, S. Ritson, W. W. Waller, R. W. Russell-Jones, A. A. Hudson, R. A. Jones, W. S. Fox, A. T. Patterson, G. R. Lawless, C. E. Lea, F. B. Dreyer, and T. C. Milligan. E. H. G. Duncan (on account of ill-health).

Temporary Lieutenants relinquishing their commissions: G. Adam, H. F. Sheldon, J. R. Irwin, R. Maclean, C. R. Learn, O. E. Ward, J. McKail, McW. Henry, J. Mallock, H. Tipping, A. J. Ferguson, J. Walker, L. S. H. Glanville, F. Simpson, A. R. Hobbs, A. G. Faulds, C. Robertson, A. L. Robinson, C. B. Gervis, N. McFarlane, H. M. Robertson, J. Gardner, E. F. Milton, W. C. Downs, J. M. Lang, and W. E. Ainley.

SPECIAL RESERVE OF OFFICERS.

The undermentioned to be Lieutenants: T. Crisp, from Edinburgh University Contingent, Officers Training Corps, and A. L. Giblin.

TERRITORIAL FORCE.

West Riding Field Ambulance: Captain G. E. St. C. Stockwell, West Yorkshire Regt., to be Captain (temporary). Attached to Units other than Medical Units.—Capt. A. G. Lovett-Campbell to be Major. Capt. J. Owen to be seconded while holding a temporary commission in the R.A.M.C.

INDIAN MEDICAL SERVICE.

Major J. W. D. Megaw, professor of pathology at King George's Medical College, Lucknow, is appointed temporarily to hold charge of the office of the Principal in the College in addition to his own duties.

PROMOTION OF LIEUTENANTS OF ROYAL ARMY MEDICAL CORPS, SPECIAL RESERVE AND TERRITORIAL FORCE.

Lieutenants appointed to commissions in the R.A.M.C., Special Reserve and Territorial Force, on or after Oct. 15th, will not be eligible for promotion to the rank of Captain until they have completed 12 months' embodied service.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In the 96 English and Welsh towns with populations exceeding 50,000 persons at the last Census 7565 births and 3919 deaths were registered during the week ended Saturday, Oct. 21st. The annual rate of mortality in these towns, which had been 13.5, 12.5, and 12.2 per 1000 in the three preceding weeks, further fell to 11.8 per 1000 in the week under notice. Among the several towns the death-rate ranged from 2.1 in Oxford, 4.5 in Acton, 5.1 in Hornsey and in Walthamstow, 5.8 in Ilford, and 6.1 in Aberdeen, to 17.0 in Barrow-in-Furness, 17.1 in Derby, 17.3 in Rochdale, 17.9 in Lincoln, and 19.2 in Burnley.

The 3919 deaths from all causes were 152 below the number in the previous week, and included 306 which were referred to the principal epidemic diseases, against numbers declining from 594 to 367 in the five preceding weeks. Of these 306 deaths, 221 resulted from infantile diarrhoeal diseases, 40 from diphtheria, 17 from measles, 11 from enteric fever, 10 from whooping-cough, and 7 from scarlet fever, but not one from small-pox. The annual death-rate from these diseases was equal to 0.9, against 1.1 per 1000 in the previous week. The deaths of infants (under 2 years) from diarrhoea and enteritis, which had declined from 477 to 259 in the five preceding weeks, further fell to 221, and included 52 in London, 18 in Liverpool, 9 in Birmingham, and 8 each in Nottingham and Sheffield. The deaths attributed to diphtheria, which had been 40, 52, and 45 in the three preceding weeks, fell to 40, of which 11 occurred in London and 3 in Coventry. The fatal cases of measles, which had been 23, 25, and 21 in the three preceding weeks, fell to 17, and included 5 in London and 2 each in Liverpool, Manchester, and Tynemouth. The deaths referred to enteric fever, which had been 11, 13, and 10 in the three preceding weeks, numbered 11, of which 2 were registered in Derby. The deaths referred to whooping-cough, which had been 20, 15, and 23 in the three preceding weeks, fell to 10, and included 2 in Hull. The fatal cases of scarlet fever, which had been 10, 13, and 9 in the three preceding weeks, fell to 7, and included 2 each in London and Liverpool.

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had increased from 980 to 1074 in the five preceding weeks, declined to 1067 on Saturday last; 125 new cases were admitted during the week, against 151, 159, and 167 in the three preceding weeks. The cases of diphtheria, which had risen from 1262 to 1410 in the five preceding weeks, further rose to 1429; 188 new cases were admitted during the week, against 193, 228, and 194 in the three preceding weeks. These hospitals also contained on Saturday last 61 cases of measles, 44 of whooping-cough, and 39 of enteric fever, but not one of small-pox. The 961 deaths from all causes in London were equal to the number in the previous week, and corresponded to an annual rate of 11.6 per 1000. The deaths referred to diseases of the respiratory system, which had been 130, 136, and 132 in the three preceding weeks, were again 132 in the week under notice.

Of the 3919 deaths from all causes in the 96 towns, 163 resulted from violence, 343 were the subject of coroners' inquests, and 1207 occurred in public institutions. The causes of 39, or 1.0 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in London and in its 14 suburban districts, in Leeds, Bristol, Bradford, Newcastle-on-Tyne, and in 56 other smaller towns. Of the 39 uncertified causes, 8 were registered in Birmingham, 6 in Liverpool, 4 in Gateshead, 3 in Preston, and 2 in Bootle.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns with an estimated aggregate population of 2,372,000 persons at the middle of this year 1026 births and 618 deaths were registered during the week ended Saturday, Oct. 14th. The annual rate of mortality in these towns, which had been 14.5, 13.6, and 15.1 per 1000 in the three preceding weeks, fell to 13.6 per 1000 in the week under notice. During the 13 weeks of last quarter the mean annual death-rate in these towns averaged 12.6, or 1.2 per 1000 above that recorded in the large English towns. Among the several towns the death-rate during the week ranged from 7.6 in Kirkcaldy, 8.3 in Leith, and 8.7 in Motherwell, to 14.4 in Paisley, 14.8 in Glasgow, and 18.2 in Dundee.

The 618 deaths from all causes were 67 below the number in the previous week, and included 61 which were referred to the principal epidemic diseases, against 75 and 92 in the two preceding weeks. Of these 61 deaths, 30 resulted from infantile diarrhoeal diseases, 16 from measles, 7 from scarlet fever, 4 from diphtheria, 3 from enteric fever, and 1 from whooping-cough, but not one from small-pox. The death-rate from these diseases was equal to 1.3, against 1.1 per 1000 in the large English towns. The deaths of infants

(under 2 years) from diarrhoea and enteritis, which had been 83, 50, and 66 in the three preceding weeks, fell to 30, and included 16 in Glasgow, 4 each in Dundee and Kilmarnock, 3 in Motherwell, and 2 in Greenock. The deaths referred to measles, which had been 4, 5, and 8 in the three preceding weeks, further rose to 16, and comprised 13 in Dundee, 2 in Glasgow, and 1 in Edinburgh. The fatal cases of scarlet fever, which had been 3, 6, and 7 in the three preceding weeks, were again 7 in the week under notice, and included 3 in Glasgow and 2 in Aberdeen. The deaths attributed to diphtheria, which had been 5, 9, and 5 in the three preceding weeks, numbered 4, of which 2 occurred in Glasgow. Of the 3 fatal cases of enteric fever, 2 were registered in Kilmarnock and 1 in Edinburgh. The death from whooping-cough occurred in Coatbridge. In addition to the above deaths, a fatal case of typhus was recorded in Dundee.

The deaths referred to diseases of the respiratory system, which had increased from 45 to 94 in the five preceding weeks, fell to 30 in the week under notice, and were 42 below the number registered in the corresponding week of last year. The deaths from violence numbered 17, against 25 and 36 in the two preceding weeks.

In the 16 largest Scotch towns 1108 births and 589 deaths were registered during the week ended Saturday, Oct. 21st. The annual rate of mortality in these towns, which had been 13.6, 15.1, and 13.6 per 1000 in the three preceding weeks, fell to 13.0 per 1000 in the week under notice. Among the several towns the death-rate ranged from 2.3 in Clydebank, 5.3 in Hamilton, and 7.6 in Kirkcaldy, to 13.8 in Paisley, 15.3 in Dundee, and 15.4 in Kilmarnock.

The 589 deaths from all causes were 29 below the number in the previous week, and included 53 which were referred to the principal epidemic diseases, against 92 and 61 in the two preceding weeks. Of these 53 deaths, 29 resulted from infantile diarrhoeal diseases, 12 from diphtheria, 4 from whooping-cough, 3 each from enteric fever and scarlet fever, and 2 from measles, but not one from small-pox. The death-rate from these diseases was equal to 1.2, against 0.9 per 1000 in the large English towns. The deaths of infants (under 2 years) from diarrhoea and enteritis, which had been 50, 66, and 30 in the three preceding weeks, were 29, and included 17 in Glasgow, 4 in Dundee, and 3 in Edinburgh. The deaths referred to diphtheria, which had been 9, 5, and 4 in the three preceding weeks, rose to 12, of which 4 were registered in Glasgow, 3 in Edinburgh, and 2 in Aberdeen. The 4 fatal cases of whooping-cough were slightly in excess of the average in recent weeks, but showed no excess in any particular town. The deaths attributed to scarlet fever, which had been 6, 7, and 7 in the three preceding weeks, fell to 3, and comprised 2 in Glasgow and 1 in Aberdeen. The 3 deaths from enteric fever, of which 2 occurred in Glasgow and 1 in Paisley, were equal to the average in the three preceding weeks. The fatal cases of measles, which had increased from 4 to 16 in the four preceding weeks, fell to 2, both of which were recorded in Dundee. In addition to the above deaths a fatal case of typhus was registered in Glasgow.

The deaths referred to diseases of the respiratory system, which had been 72, 94, and 90 in the three preceding weeks, fell to 74 in the week under notice, and were 62 below the number registered in the corresponding week of last year. The deaths from violence numbered 26, against 36 and 17 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the registration district of Dublin 198 births and 135 deaths were registered during the week ended Saturday, Oct. 14th. The annual rate of mortality, which had been 15.6, 18.3, and 18.7 per 1000 in the three preceding weeks, fell to 17.7 in the week under notice, against 11.7 and 14.8 per 1000 in London and Glasgow respectively.

The 135 deaths from all causes included 32 of infants under 1 year and 35 of persons aged 65 years and upwards. Fourteen deaths (of infants under 2 years) were referred to diarrhoeal diseases, 3 to enteric fever, 2 to whooping-cough, and 1 each to measles and diphtheria. The causes of 7 deaths were uncertified, and those of 4 others were the subject of coroners' inquests, while 58, or 43 per cent., of the total deaths occurred in public institutions.

During the same period 183 births and 102 deaths were registered in the city of Belfast. The deaths corresponded to an annual rate of 13.6, or 0.4 per 1000 less than in the previous week, and included 23 of infants under 1 year and 21 of persons aged 65 years and upwards. Nine deaths (of infants under 2 years) were referred to diarrhoeal diseases, and 1 each to enteric fever, measles, and whooping-cough. The causes of 3 deaths were the subject of coroners' inquests, and that of 1 other was uncertified, while 24 of the total deaths occurred in public institutions.

In the registration area of Dublin 189 births and 133 deaths were registered during the week ended Saturday, Oct. 21st. The annual rate of mortality, which had been 18.3, 18.7, and 17.7 per 1000 in the three preceding weeks, fell to 17.5 in the week under notice, against 11.6 and 13.7 per 1000 in London and Glasgow respectively.

The 133 deaths from all causes included 27 of infants under 1 year and 30 of persons aged 65 years and upwards. Three deaths were referred to enteric fever, 3 (of infants under 2 years) to diarrhoeal diseases, and 1 each to measles, and scarlet fever. The causes of 5 deaths were the subject of coroners' inquests, and those of 4 others were uncertified, while 59, or 44 per cent., of the total deaths occurred in public institutions.

During the same period 173 births and 98 deaths were registered in the city of Belfast. The deaths corresponded to an annual rate of 13.1, or 0.5 per 1000 less than that recorded in the previous week, and included 18 of infants under 1 year and 18 of persons aged 65 years and upwards. Six deaths of infants (under 2 years) were referred to diarrhoeal diseases, 2 to enteric fever, and 1 each to scarlet fever and diphtheria. The causes of 8 deaths were the subject of coroners' inquests, and 29 of the total deaths occurred in public institutions.

Obituary.

PROFESSOR ALBERT NEISSER.

By the death of Professor Albert Neisser on July 30th Germany lost one of her greatest scientists, and the whole world is the poorer for the loss. Like so many of the most distinguished scientists of the last century in Germany, Neisser was of Semitic descent. He was born on Jan. 22nd, 1855, near Breslau, and was the son of Moritz Neisser, also a distinguished physician. Albert Neisser's career was associated with Breslau almost uninterruptedly. His medical studies were conducted in Breslau and Erlangen. In 1877 he received the M.D. for his thesis on "Die Echinokokkenkrankheit." In 1879 he drew attention to the presence in gonorrhoeal discharge of certain cocci, whose characteristics were sufficiently distinctive to warrant their identification with the causation of gonorrhoea. He was attached as assistant to the Breslau University Hospital and Polyclinic for Syphilis and Diseases of the Skin under Oskar Simon, whose death in 1882 created a vacancy which was filled by Neisser, then only 27. Breslau's early recognition of Neisser's abilities was amply justified by subsequent events, and was rewarded by the loyalty he showed to his Alma Mater. He refused every offer of promotion elsewhere, including the succession to Lewin in Berlin in 1896. Under Neisser's supervision the primitive, prison-like buildings of the Allerheiligen Hospital were replaced in 1892 by a thoroughly up to date and fully equipped hospital. In 1902 he founded "Deutsche Gesellschaft zur Bekämpfung der Geschlechtskrankheiten." The discovery by Metchnikoff and Roux of the susceptibility of monkeys to syphilis in 1903 led Neisser in the following year to initiate a vast scheme of experimental study of syphilis in monkeys. Accompanied by his wife and two assistants, he started early in 1905 on his expedition to Java, where he remained several months, studying the conditions under which syphilis occurs in the monkey. It was during Neisser's absence from home that the *Spirochaeta pallida* was discovered by Schaudinn and Hoffmann. Their observations were quickly confirmed in Java by Neisser. In conjunction with Bruck and Wassermann, Neisser contributed much of the spade work on which the reaction, now known as Wassermann's, is based. He travelled in Norway and Spain to study leprosy, and he contributed a vast amount of clinical and bacteriological observation to the study of syphilis. But his name will always be primarily associated with gonorrhoea; he was not only, as his countrymen affectionately call him, "the Father of the Gonococcus," but also a pioneer in the rational treatment of gonorrhoea. He insisted on the constant control of treatment by the microscope, he combated the indiscriminate use of astringents to the exclusion of other drugs, and he was the first to recommend protargol in gonorrhoea. For his experiment of injecting syphilitic serum into four healthy persons Neisser incurred the ill will of the authorities in 1900. He was publicly reprimanded and fined, and he does not appear to have been compensated for this unwelcome notoriety by any valuable observations from his daring and illegal experiments.

His health had been failing for some years, and he had suffered from diabetes for a long time. A few years before his death he fractured one thigh by a fall in a cellar; he was confined to bed for several months and never recovered his former vitality. He was also subject to nephrolithiasis, and in July of this year he insisted on travelling to Brussels to

attend an exhibition, although he was suffering from renal colic, complicated by cystitis. On his return home he attempted to attend a meeting in Düsseldorf, but was forced instead to retire to Berlin where, on July 21st, he was operated on for a stone which had descended to the bladder. Two days later he returned to Breslau. Here sepsis and high fever developed, and he died on July 30th, having been comatose for a day.

RALPH BROWN, M.D., B.S. LOND., M.R.C.S. ENG.,

L.R.C.P. LOND.,

SENIOR ASSISTANT PHYSICIAN AND DEPUTY MEDICAL SUPERINTENDENT, BETHLEM AND BRIDEWELL ROYAL HOSPITALS.

ONE of a large family of sons, all serving their country, Ralph Brown had volunteered for a commission in the Royal Army Medical Corps, when his untimely death on Oct. 6th occurred from typhoid fever.

Ralph Brown was born in 1880 and educated at Sherborne School and University College, London, where he quickly showed brilliant promise. He became prosector of anatomy, and later gained the gold medal in materia medica and therapeutics. Owing to the fact that University College Hospital was in the process of being rebuilt, he transferred in 1903 to Westminster Hospital, where he gained the scholarship for third-year students. He took the English Conjoint Diploma in 1906 and graduated M.B., B.S. at the University of London in 1908. At Westminster he held in turn the usual resident posts, and later became house physician to Bethlem Royal Hospital, having decided to specialise in psychological medicine. He was appointed resident medical officer to Moorcroft Asylum, Hillingdon, but in 1911 he returned to Bethlem as junior assistant physician, becoming also assistant medical officer to King Edward Schools, London and Witley. In 1913 he took his Doctorate of Medicine by passing in psychology and mental diseases, and in 1914 was appointed senior assistant physician to Bethlem.

Of a quiet and retiring disposition, his kindness of heart and sympathetic manner were as obvious as his scientific attainments. The future would have held much success in store for him.

One of Ralph Brown's brothers is a prisoner of war and another was killed fighting in Flanders.

FRANCIS CLARE MELHADO,

SECRETARY-SUPERINTENDENT OF THE MIDDLESEX HOSPITAL.

WE regret sincerely the death of Mr. F. Clare Melhado, secretary-superintendent of the Middlesex Hospital, on Oct. 18th, at the age of 54. He had been connected with the Middlesex Hospital since 1879, and had held the appointment of secretary-superintendent since 1888. His loss to the institution will be most severely felt, for he had devoted all his energies to its welfare. Mr. Melhado had a large circle of friends, including the members of the Weekly Board, the consulting and acting staff, and numerous men who had been students of the hospital. His genial and courteous manner made him universally popular, and it was everywhere recognised that he was eager and willing to subjugate all other matters to the benefit of the hospital to which he was so devoted.

THE LATE MR. CHAUNCY PUZEY.

Mr. R. W. Murray, F.R.C.S., writes:—

May I be permitted to supplement the short obituary notice which appears in THE LANCET of Oct. 21st concerning my old friend Chauncy Puzey. Puzey made his reputation as a surgeon in the early antiseptic days, and was probably the first surgeon in Liverpool to prepare and use an absorbable catgut ligature. The basis upon which his reputation rested was his sound surgical judgment and well-thought-out opinion. He was by no means a bold surgeon or a brilliant operator. Before he undertook any operation, no matter how trivial, the reason for the operation was always carefully considered and the various steps thought out in detail. He was scrupulously clean in his methods and obtained excellent results. Puzey was never an ambitious man, and his deliberate and punctilious manner prevented him from ever acquiring a large consulting practice, but so highly was his opinion valued by those who knew him that had one of his colleagues been threatened with the loss of a limb he would not have consented to amputation being performed unless Puzey said it was really necessary.

"Audi alteram partem."

ATMOSPHERIC CONDITIONS IN RELATION TO TRENCH FEVER.

To the Editor of THE LANCET.

SIR,—In continuation of the suggestion made by me in THE LANCET of August 19th that the atmospheric conditions in the trenches may be the cause of trench fever, I give in the accompanying table the atmospheric conditions at the Parc de Saint-Maur Observatory, Paris, for 11 hours continuously on July 17th, 1912:—

(A) Hourly Atmospheric Conditions at the Parc de Saint-Maur Observatory, Paris, July 17th, 1912.

(B) Atmospheric Conditions which Raised Body Temperature in the Spinning and Weaving Sheds.

(C) Degree to which Temperature was Raised by Exposure in the Spinning and Weaving Sheds.

| | (A) | | | | (B) | | | (C) | | |
|--------|---------------------------|-----------|-------------------------------------|------------------------------|---------------------------|-----------|-------------------------------------|----------------------------------|--------|--------------|
| | Temperature of air (°F.). | | Drying power of air per 10 cub. ft. | Velocity of wind per second. | Temperature of air (°F.). | | Drying power of air per 10 cub. ft. | Body temperature in mouth (°F.). | Pulse. | Respiration. |
| 1 P.M. | Dry. 85.5 | Wet. 71.8 | Gr. 63.6 | 3 | Dry. 85.5 | Wet. 78.0 | Gr. 44.0 | 100.1 | 82 | 22 |
| 2 .. | 83.6 | 68.7 | 67.6 | 3 | 83.5 | 74.0 | 50.0 | 99.8 | 116 | 20 |
| 3 .. | 82.4 | 68.9 | 61.2 | 5 | 82.0 | 77.0 | 28.0 | 100.2 | 80 | 24 |
| 4 .. | 82.5 | 70.1 | 39.1 | 4 | 82.0 | 77.0 | 28.0 | 100.2 | 80 | 24 |
| 5 .. | 82.9 | 67.7 | 64.5 | 3 | 83.0 | 74.0 | 47.0 | 99.8 | 104 | 21 |
| 6 .. | 79.8 | 72.2 | 34.8 | 3 | 80.0 | 71.0 | 44.0 | 100.0 | 90 | 24 |
| 7 .. | 77.0 | 70.5 | 31.0 | 2 | 77.0 | 70.0 | 33.0 | 100.0 | 100 | 26 |
| 8 .. | 75.2 | 69.3 | 21.0 | 0 | 75.0 | 69.5 | 26.6 | 100.2 | 110 | 18 |
| 9 .. | 73.4 | 67.8 | 23.2 | 1 | 73.5 | 68.0 | 24.5 | 100.0 | 90 | 22 |
| 10 .. | 71.7 | 66.7 | 17.6 | 2 | 72.0 | 67.0 | 18.0 | 100.0 | 72 | 14 |
| 11 .. | 71.4 | 67.8 | 10.8 | 0 | 72.0 | 67.0 | 18.0 | 100.0 | 72 | 14 |

Conditions marked (a) will cause pyrexia; (b) will not cause pyrexia. In the experiment (B) no movement of the air was perceptible.

The record of atmospheric conditions at the Parc de Saint-Maur is taken from the "Annales du Bureau Central Météorologique de France," 1912, published by M. Angot, the Director. I have, however, converted the centigrade reading into Fahrenheit, and instead of giving the relative humidity of the air, I have given the wet-bulb temperature and the drying power of the air calculated from the dry-bulb temperature and the relative humidity. This I have done in order to render easier a comparison with the conditions which are known to raise body temperature in the humid cotton- and linen-weaving sheds in Lancashire and in Ireland.

In line with each hourly observation at the Parc de Saint-Maur I have placed a record of atmospheric conditions which so raised the body temperature of a considerable number of the operatives in the humid cotton-weaving sheds in Lancashire and in the humid linen-weaving sheds in Ireland. Comparing these atmospheres it is evident that the atmospheric conditions marked (a) at the Parc de Saint-Maur on July 17th, 1912, were for six hours continuously such as would cause pyrexia in many. For they present a greater impediment to loss of heat from the body, especially by evaporation, than the conditions in the cotton spinning and weaving sheds. But the latter raised the body temperature of many of the operatives to 37.7° C. (100.0° F.) or higher in less than four hours. Hence I conclude that the atmospheric conditions at the Parc de Saint-Maur from 5 P.M. to 11 P.M. on July 17th, 1912, were such as would cause a pyrexia of short duration in some.

It may be objected that even if the atmospheric conditions at the Parc de Saint-Maur are such as produce fever it does not follow that the atmospheric conditions in the trenches are similar. Such objection is reasonable and

cannot be answered satisfactorily without actual meteorological observations in the trenches or in their vicinity. The nearest stations to the trenches at which suitable observations were recorded are, I am informed by M. Angot, Arras and Lille, and he adds that they are at the present moment lost.

It is probable, however, that the atmosphere of the trenches is more humid, from the proximity of the marshes in "No Man's Land," than the atmosphere of the Parc de Saint-Maur. Such greater humidity would present a greater impediment to loss of heat from the body by evaporation and would, the temperature and movement of both atmospheres being the same, raise body temperature more than the atmosphere in the Parc de Saint-Maur. But comparison of the Parc de Saint-Maur atmosphere with that in the cotton-sheds shows that for six hours continuously on July 17th, 1912, it was such as would raise body temperature above 37.7° C. (100.0° F.)—that is, it was such as would produce in many, in less than four hours, a pyrexia of short duration. This shows, at all events, that in France the atmospheric conditions in the summer are sometimes such as will cause fever.

For these reasons I think that the atmospheric conditions in the trenches and in their vicinity deserve investigation as a possible cause of a pyrexia of short duration with relapses, such as trench fever is described to be.

I am, Sir, yours faithfully,

MATHEW D. O'CONNELL, M.D. R.U.I.

Harrogate, Oct. 14th, 1916.

Colonel, R.P.; late A.M.S.

TRENCH PYREXIAS.

To the Editor of THE LANCET.

SIR,—In your issue of Sept. 9th there appears a short note on Trench Pyrexias, being a contribution to the etiology of what is popularly but quite incorrectly described as "trench" fever.

It is to the author's suggestions as to the causation of the disease that I should like to draw attention. He adduces (1) the trench rat, with which he presumably includes its accompanying parasites, and (2) reluctance on the part of the men to go to the latrines when in the trenches on account of the danger of being knocked over while there, with resultant constipation. I am afraid that neither of these suggestions will account for the facts. Last winter, while on the staff of a casualty clearing station, I made a study of cases of the type of disease alluded to as "trench pyrexias." I saw over 200 of them and made clinical memoranda on 50. While most occurred in men from the trenches a fair proportion of the patients had never been within 12 miles of the front line, had never seen a "trench" rat (not that he differs from any other), and had no cause to refrain from visiting the latrines as often as they wished. I cannot remember whether the author mentions lice as a possible source of infection. This has been suggested, but cannot be accepted, for I have known the symptoms to occur in men who had never suffered from pediculosis, among others in the staff of a D.D.M.S., who lived in a château with all modern conveniences.

As for my own cases, after sorting out paratyphoid cases (of which I saw only three), incipient pleurisy and pneumonia, and trench nephritis, I came to the conclusion that the remainder could be attributed to influenza in what (for I know not what reason) has been described as its "nervous" form. "Trench" pyrexias do not, I consider, differ in any way from those met with in civil practice.

My experience as to the course of the disease differed from that of the author in that I found that the pyrexia often lasted from five to ten days and sometimes longer. In those cases of more or less prolonged fever I found the subsequent prostration was often considerable. In fact, towards the end of my work with these cases I made it a rule to send on to the base all those who ran a temperature on the fifth day from the onset of the fever. I further found that relapses were of common occurrence.

The most marked clinical features of the disease as I saw it were the pains in the loins and shins and headache. The pains in the legs I found particularly hard to treat.

Trusting that you will pardon the disjointed nature of these remarks, and apologising for the enforced use of pencil,

I am, Sir, yours faithfully,

B. E. F., France, Sept. 22nd, 1916.

S. C. DYKE.

"ORTHOPÆDICS" AND PHYSICAL TREATMENT.

To the Editor of THE LANCET.

SIR,—More could and should be done to relieve the disablement of wounded soldiers, particularly of those who are discharged as no longer fit for military duty. In the medical and lay press there is some little confusion of terms. A demand is made for a wide extension of "orthopædic treatment" for the benefit of the classes just mentioned, and what is apparently intended is not alone surgical aid, but also the "combined physical treatment," by means of baths, massage, exercises, and electricity, which is being gradually introduced into this country, and which has been found so beneficial for the wounded. The word "orthopædics" is assuming a much wider meaning, since in the new military hospitals called by that name stiff limbs and wasted muscles are to form a large proportion of the cases treated.

With the precision of thought and language, which is so delightful in some of our continental colleagues, Dr. Delterre, the medical director of the Anglo-Belge Hospital for disabled soldiers at Rouen, defines the three departments of his work as (1) *interventions chirurgicales*, (2) *prothèse* (splints and artificial limbs), (3) *physiothérapie*. These are all regarded as independent branches of the medical art and are placed under the direction of experts, but for the case of wounded soldiers are considered essential and interdependent. In our country *interventions chirurgicales* and *prothèse* have attained a high position. The third, *physiothérapie*, as it is now practised, is a definite method of treatment applicable to the large majority of disabled soldiers. This method, or group of methods, being physical, has strong affinities with physical training and re-education. Therefore it pertains, not to the hospital ward, but to the camp or clinic. Its value and close connexion with training and industrial education have been recently proved in our own country at the Command Dépôts of Heaton Park and Tipperary.¹

A special committee of the Royal Society of Medicine (Section of Balneology) has for two years been studying the best means of applying these methods of treatment to the wounded in the British Islands. None know better than the committee how wide is the scope of this matter and how many are the problems involved in it. It may be gravely doubted whether physical treatment as it is now understood can be adequately given in the wards of orthopædic hospitals and even whether it is possible that the surgeons, who are so fully occupied with *interventions chirurgicales*, can give time or study to it.

It is submitted that the question for to-day is: How and where can these combined physical remedies best be provided for unknown numbers of wounded? Their great importance has now been generally admitted, and their special value in the care of disabled soldiers fully established. Surely it is an urgent necessity in the first place that a sufficient number of medical men should specialise in the study and administration of physical treatment, and it is most desirable that as the need for it increases throughout the country there should be no lack of men competent to undertake its supervision.

I am, Sir, yours faithfully,

London, Oct. 16th, 1916.

R. FORTESCUE FOX.

THE PREPARATION OF STABLE COLLOIDAL ANTIMONY.

To the Editor of THE LANCET.

SIR,—Your correspondent, Dr. Upendra Nath Brahmachari, whilst referring to "the brilliant results" obtained by the use of colloidal metals, in THE LANCET of Oct. 21st, is in error in assuming that stable solutions of colloidal antimony are not to be obtained. The late Mr. Henry Crookes not only prepared a perfectly stable solution of colloidal antimony in the Crookes' laboratories as long ago as 1912, but that preparation (collosol antimony) is perfectly stable to-day, and exhibits most active Brownian movement. Moreover, the tests made by Mr. Henry Crookes showed that antimony was

strongly inhibitory to such micro-organisms as the *B. coli communis*, *B. prodigiosus*, and the staphylococci, and the results of further experiments upon the *B. phosphorescens* (exhibited by Mr. Crookes to the Royal Society) showed antimony together with arsenic and silver at the head of a list of 22 metals in bactericidal effect.

In the absence of opportunity for clinical experiment its specific action in leishmaniosis was not then tested, as the properties of the collosols were not appreciated at that time. Since then, the Crookes Laboratories have been too much occupied with the production of other metallic colloids, and more recently with the collosols of iodine and sulphur, to deal comprehensively with collosol antimony, but a supply of this colloid—which has stood the test of four years and now exhibits ultra-microscopically equal stability and activity of Brownian movement to that occurring when it was first tested by Sir William Crookes in 1912—is still available. Moreover, being a chemically prepared colloid, it does not break down in the presence of electrolytes, as has been so amply proved in the case of the electrically prepared colloidal solutions.—I am, Sir, yours faithfully,

LEWIS STROUD, M.A. Oxon.

The Crookes Laboratories, 50, Egin-crescent, W.,
Oct. 24th, 1916.

MEDICAL WOMEN AND EQUALITY OF PAY.

To the Editor of THE LANCET.

SIR,—With regard to a letter under this heading published in THE LANCET of Oct. 14th, I should like to suggest that at the present time it is the duty of the Government to get any work done at the lowest possible figure compatible with efficiency. If patriotic medical women would remember that thousands of men have been deprived of homes, incomes, and lives in order that the more fortunate of us may live, we might hear less of the injustice in giving women only £400 a year. We ought to be conscripted and put on a separation allowance. There is no justice in war, and those who are fighting get least, as far as I can see.

I am, Sir, yours faithfully,

KATHARINE M. MACKENZIE.

Ayrshire Sanatorium, New Cumnock, Oct. 24th, 1916.

"CLERGYMEN'S SORE-THROAT."

To the Editor of THE LANCET.

SIR,—The bad effects produced upon the throats of clergymen by speaking downwards have been long recognised by laryngologists and were first pointed out many years ago by Dr. Whipple. This fact will be found referred to in my text-book on "Diseases of the Throat, Nose and Ear," third edition, p. 54.

I am, Sir, yours faithfully,

Oct. 23rd, 1916.

P. MCBRIDE.

FALLOPIAN TUBE FOUND IN FEMORAL HERNIA.

To the Editor of THE LANCET.

SIR,—In the year 1882 I had a similar case to the one reported in THE LANCET last week by Mr. E. G. Renny (on the right side) when I was dresser to the late Sir Henry G. Howse at Guy's. The patient was a single woman, aged 25 or 26. The sac when opened contained some omentum, and the fimbriated extremity of the Fallopian tube was covered by this. I feel sure that Sir Henry Howse must have placed this case on record—probably in the Guy's Hospital Reports.

I am, Sir, yours faithfully,

Northfleet, Kent, Oct. 24th, 1916.

H. T. SELLS.

CHADWICK PUBLIC LECTURES.—The autumn programme of Chadwick lectures includes three lectures by Professor Wm. Stirling on Fatigue, and its Effects on Industry and Efficiency (Fridays, Oct. 27th and Nov. 3rd and 10th, at 5.15 P.M., in the Lecture-room of the Royal Society of Arts, John-street, Adelphi); three lectures by Dr. Charles Porter, medical officer of health of Marylebone, on The Health of the Future Citizen (Thursdays, Nov. 2nd and 9th, and Tuesday, Nov. 14th, at 3 P.M., in the Norwich Museum); a lecture by Dr. J. T. C. Nash, county medical officer of health of Norfolk, on Baby-Saving for the Nation (Monday, Nov. 20th, at 5 P.M., in the Hampstead Central Library, Finchley-road). All the lectures will be illustrated by lantern slides. Admission is free.

¹ See Major R. Tait McKenzie's paper on the Treatment of Convalescent Soldiers by Physical Means read before the Royal Society of Medicine, July 21st, and Mr. Cyril Jackson's letter on "Broken Soldiers" in the Times of Sept. 15th.

The War.

THE CASUALTY LIST.

The following names of medical officers appear among the casualties announced since our last issue :—

Killed.

Capt. G. M. Levack, R.A.M.C., attached Oxford and Bucks Light Infantry, qualified M.B., Ch.B. Edin. in 1914, and at once took up Army work. He was with the Seaforth Highlanders for 12 months, and took part in several actions in which his battalion was engaged.

Capt. W. R. Pagen, R.A.M.C., attached East Kent Regiment, was educated at Durham University and at the London Hospital, and qualified in 1905. Previous to joining the R.A.M.C. he was in practice at Cockermouth, and was the medical officer of No. 1 District of the Cockermouth Union.

Captain R. E. Horkins, R.A.M.C., attached Royal Field Artillery, came over with the Canadian Expeditionary Force.

Lieut. S. A. Walker, R.A.M.C., attached Cheshire Regiment, came over with the Canadian Expeditionary Force.

Died.

Capt. W. Crymble, R.A.M.C., was educated at Belfast and at Dublin, and qualified in 1909. He had held appointments at the Down District Asylum and at the Royal Victoria Hospital, Belfast, and was also senior assistant medical officer at the Beckett-street Infirmary, Leeds. He went to France at the beginning of the war and was taken prisoner. He was released later and served in the Near East, where he contracted enteric fever, and died at Alexandria.

Wounded.

Lieut. P. S. MacLaren, R.A.M.C., attached Royal Scots.

Lieut. J. E. Thompson, R.A.M.C., attached Liverpool Regt.

Capt. T. I. Dun, R.A.M.C.

Major G. S. Mothersill, C.A.M.C., attached Canadian Infantry.

Lieut. A. Davidson, R.A.M.C., attached London Regiment.

Capt. J. C. Matthews, R.A.M.C., attached Liverpool Regiment.

Capt. S. A. Montgomery, R.A.M.C.

Capt. S. Miller, R.A.M.C.

Capt. J. E. Bruneau, R.A.M.C.

Lieut. P. G. Leeman, R.A.M.C.

Capt. R. Silcock, R.A.M.C.

Capt. J. H. Wood, C.A.M.C.

Capt. W. G. Grant, R.A.M.C., attached Essex Regiment.

Capt. J. J. Field, R.A.M.C.

Capt. R. R. Scott, R.A.M.C.

Previously reported believed taken Prisoner at Kut-el-Amara, now reported Prisoner.

Capt. M. L. Puri, I.M.S.

THE HONOURS LIST.

The following awards to medical officers are announced :—

D. S. O.

Surg.-Major Francis William Bailey, R.F.A. (Medical Officer).

For conspicuous gallantry and devotion to duty. When the batteries of his brigade came under heavy shell-fire he at once went out into the open to tend the wounded and dying, with utter disregard of danger.

Major Michael Joseph Mahoney, R.A.M.C.

For conspicuous gallantry and devotion to duty in action. When his aid-post was blown in he at once established another under heavy shell-fire and tended the wounded for two days and nights. When relieved he took a few hours' rest and then returned to his gallant work.

Capt. Joseph Ellis Milne, R.A.M.C.

For conspicuous gallantry and devotion to duty during operations. He has repeatedly tended the wounded under heavy shell-fire, and has shown himself utterly regardless of personal safety.

Capt. Edgar Percival, R.A.M.C.

For conspicuous gallantry and devotion to duty. He led a party of stretcher-bearers into a wood, and remained for over two hours searching for wounded under shell and machine-gun fire. On previous occasions he has done similar gallant work.

Military Cross.

Temp. Capt. Harold Ackroyd, R.A.M.C.

For conspicuous gallantry and devotion to duty during operations. He attended the wounded under heavy fire, and finally, when he had seen that all our wounded from behind the line had been got in, he went out beyond the front line and brought in both our own and enemy wounded, although continually sniped at.

Temp. Lieut. Frederick Alexander Anderson, R.A.M.C.

For conspicuous gallantry and devotion to duty. When his aid-post was hit and all his assistants were wounded, he himself being badly bruised, he helped to dig out three buried men under heavy shell-fire. He stuck to his duty till his battalion was relieved.

Temp. Lieut. Bernard Francis Bailey, R.A.M.C.

For conspicuous gallantry and devotion to duty during operations. For two days and nights he tended the wounded under heavy shell-fire. He was stunned by a shell, but, on regaining consciousness half an hour later, continued his fine work with the greatest coolness.

Temp. Capt. Cyril Carlyle Beatty, R.A.M.C.

For conspicuous courage and coolness when in charge of an advanced dressing-station. By his fine work he has ensured quick and successful evacuation of wounded from the aid-posts. In times of difficulty he set an invaluable example.

Temp. Lieut. James Gordon Bell, R.A.M.C.

For conspicuous gallantry and devotion to duty. He tended the wounded under heavy shell-fire. On being relieved he heard that some wounded men had been left in a trench and immediately went back 2½ miles with a stretcher party through heavy shelling and brought in three wounded men.

Temp. Capt. Thomas Bourne-Price, R.A.M.C.

For conspicuous gallantry and devotion to duty during operations. He went from place to place under very shell-fire to try and get into communication with the ambulance cars. Finally, he was half-smothered by the explosion of three successive heavy shells. For many months he has done very fine and gallant work when in charge of stretcher-bearers, and when tending and evacuating wounded under shell-fire.

Capt. William Bowater, R.A.M.C.

For conspicuous gallantry and devotion to duty during operations. He collected the wounded from the front-line trenches and advanced dressing-stations under heavy shell-fire during several days. He allowed himself hardly any rest, and set a fine example to his men.

Capt. Samuel Brown, R.A.M.C.

For conspicuous devotion to duty during operations. He was blown up by a shell and so much injured that he had to spend the night in a field ambulance; but, though still suffering, he returned to duty next day. A few days later he was again blown up. He has never spared himself, and has displayed the greatest gallantry.

Temp. Capt. William Campbell, R.A.M.C.

For conspicuous gallantry and devotion to duty during operations. He repeatedly attended the wounded under heavy shell-fire. On one occasion, when a dug-out had been hit by a gas shell, he went in to attempt the rescue of those within under very dangerous conditions.

Temp. Lieut. John Russell Christian, R.A.M.C.

For conspicuous gallantry and devotion to duty. When Brigade Headquarters was shelled by the enemy, one man being mortally wounded and two officers incapacitated, he remained with them all night exposed to shell-fire. After the wounded had been removed to safety, he remained behind in order that other units might know where to find him. He has done other fine work.

Temp. Capt. Arthur Gruchy Clark, R.A.M.C.

For conspicuous gallantry and good work, controlling bearers at the front under very heavy fire. He did especially good work in advanced trenches.

Temp. Lieut. Vincent Middleton Coates, R.A.M.C.

For conspicuous gallantry and devotion to duty in action. During an attack he tended the wounded under very difficult circumstances, working without assistance after his orderly was hit. He was under heavy shell-fire.

Capt. Aston Ridley Dale, R.A.M.C., Special Reserve.

For conspicuous gallantry and devotion to duty during operations. He was untiring in his efforts on behalf of the wounded, and showed great courage when a shell burst in the entrance to his dressing-station, killing his orderly and wounding a sergeant.

Temp. Capt. Douglas Allan Donald, R.A.M.C.

For conspicuous gallantry and devotion to duty during operations. When a dug-out was hit by a gas shell, he twice entered and removed two wounded men under very dangerous conditions. He had previously been working continuously for 48 hours removing the wounded from aid-posts.

Temp. Lieut. Richard Felton, R.A.M.C.

For conspicuous gallantry and devotion to duty during operations. He tended the wounded during an intense bombardment, and, a few days later, when a shell blew in the orderly room, killing three men and burying the remainder, he rescued the latter under most dangerous conditions. But for his pluck and devotion to duty many more lives would have been lost.

Temp. Capt. William Eric Giblin, R.A.M.C.

For conspicuous gallantry and devotion to duty in action. He tended the wounded in "No Man's Land" under heavy shell and machine-gun fire, and showed an utter contempt of danger.

Capt. Samuel Sowray Greaves, R.A.M.C.

For conspicuous gallantry and devotion to duty in action. For 36 hours he tended the wounded in the open. On several other occasions he has shown great courage under heavy shell-fire.

Temp. Capt. John Greene, R.A.M.C.

For conspicuous gallantry and devotion to duty during operations. He tended the wounded under heavy shell-fire, though himself injured by a shell which burst only 10 yards from him. He immediately returned to duty after being tended at the dressing station.

Capt. Eben Stuart Burt Hamilton, R.A.M.C., Special Reserve.

For conspicuous gallantry and devotion to duty during operations. He rescued three severely wounded men from the ruins of a dug-out under heavy shell-fire. As he was removing the last man the dug-out was blown in on him, and he had himself to be dug out. He has done other fine work and has shown an utter disregard of danger.

Temp. Capt. John Bowman Hunter, R.A.M.C.

For conspicuous gallantry and devotion to duty during operations. He tended the wounded under heavy shell-fire when the battalion had suffered heavy casualties. By his fine example he inspired all under him with courage and energy.

Temp. Capt. Ernest Emrys Isaac, R.A.M.C.

For conspicuous gallantry and devotion to duty during operations. He tended the wounded in a very exposed position for 12 hours, some of them being wounded and one actually killed by shell-fire in his aid-post. At one time he had worked unceasingly for 35 hours without food, drink, or rest, having divided up his food and water among those of the wounded who most needed it.

Capt. Frank Graham Lescher, R.A.M.C., Special Reserve.

For conspicuous gallantry and initiative in searching for wounded under heavy shell-fire. He repeatedly led his bearers through heavy barrage. He continued his work until he had got all the wounded to safety.

Temp. Capt. Kenneth William Mackenzie, R.A.M.C.

For conspicuous gallantry and devotion to duty during operations. His aid-post was continually shelled, but he carried on with great determination. He personally assisted some of the walking cases across the shelled area, and when water ran out, went himself across the open to get some. He showed an utter disregard of personal safety.

Temp. Lieut. George Boyd McTavish, R.A.M.C.

For conspicuous gallantry and devotion to duty. Throughout very severe fighting he was responsible, by his energy, courage, and contempt for danger, in saving a large number of severely wounded who had been left in the battered front-line trenches or in "No Man's Land."

Temp. Lieut. Gregor Mackenzie Miller, R.A.M.C.

For conspicuous gallantry and devotion to duty during operations. By his splendid example and cheerfulness he gave great encouragement to the men under heavy and continuous shell-fire. He volunteered to remain in the front-line trenches, where he saved the lives of many badly wounded men by being on the spot.

Temp. Capt. Francis John Morris, R.A.M.C.

For conspicuous gallantry and devotion to duty during operations. He led his stretcher-bearers to collect wounded in full view of the enemy's position, and set a fine example to all near him. He has done other similar gallant work.

Temp. Capt. Bartholomew Joseph Mullin, R.A.M.C.

For conspicuous gallantry and devotion to duty during operations. He tended the wounded under heavy shell-fire after himself being knocked down by a shell. He had to work in an open trench without any overhead cover and exposed to enfilade fire.

Capt. Hugh Roger Partridge, R.A.M.C.

For conspicuous gallantry and devotion to duty during operations. During several weeks he was in charge of a collecting post and repeatedly under heavy shell-fire. He has shown the greatest coolness, and has worked incessantly evacuating the wounded. He has been hit more than once by debris, and has set a fine example to those around him.

Temp. Capt. Wellington Le Roy Pedlow, R.A.M.C.

For conspicuous gallantry and devotion to duty during operations. He tended the wounded utterly regardless of the enemy's fire, and carried a severely wounded officer from a very exposed part of the captured position to the aid-post, being fired at all the way.

Capt. Rudolph Albert Peters, R.A.M.C., Special Reserve.

For conspicuous gallantry and devotion to duty during operations. He tended the wounded the whole day and night under heavy shell-fire, and at night was instrumental in getting in many wounded who were lying out in front in the open.

Temp. Capt. Nicol McNicoll Rankin, R.A.M.C.

For conspicuous gallantry and devotion to duty in remaining at his post and attending to the wounded after the regimental aid-post had received three direct hits and he himself had been wounded in the face. For four hours he continued at duty, the area around his aid-post being heavily shelled all the time.

Temp. Capt. Charles Roche, R.A.M.C.

For conspicuous courage and skill in the performance of his duties, many times under fire. He organised large stretcher parties and rescued many seriously wounded men from points which were constantly under heavy fire. He has displayed great devotion to duty under distressing circumstances.

Capt. Hugh Kingsley Ward, R.A.M.C., Special Reserve.

For conspicuous gallantry and devotion to duty during operations. He has shown an utter contempt for danger, going to any and every place, however exposed, in which there were wounded men. He has himself been wounded by a shell while carrying out this gallant work.

Capt. Albert Groenewald, Medical Officer (attached South African Horse).

For conspicuous gallantry and devotion to duty during several actions. He tended the wounded under fire with utter disregard to his personal safety.

Capt. Stephen Liebson, South African Medical Corps.

For conspicuous gallantry and devotion to duty when tending the wounded during operations. Though himself wounded and with nothing but a small trench to work in, he carried on during several days under heavy shell and sniping fire with the greatest courage.

*Bar to Military Cross.***Temp. Capt. William Howard Lister, M.C., R.A.M.C.**

For conspicuous gallantry and devotion to duty during operations. For 30 hours he supervised the work of his stretcher-bearers in the open under heavy shell-fire. On another occasion he searched a wood for wounded under very heavy shell-fire.

(The award of the Military Cross was announced in THE LANCET of June 26th, 1915.)

The following awards are in connexion with the operations in Mesopotamia:—

*Distinguished Service Order.***Major Ernest Vaughan Aylen, R.A.M.C.**

Lieut.-Col. Hubert Oliver Browne Browne-Mason, R.A.M.C.
Capt. Reginald Charles Clifford, I.M.S.
Capt. Leo Murphy, R.A.M.C.

*Military Cross.***Capt. David Arthur, I.M.S.**

Capt. Albert Thomas James McCreery, R.A.M.C.

MENTIONED IN DESPATCHES.

The names of the following medical officers are mentioned in despatches received from Lieut.-General Sir Percy Lake, K.C.B., in connexion with the operations in Mesopotamia and for the relief of Kut-el-Amara:—

Royal Navy.—Staff-Surg. E. Cameron and Surg. F. G. Hitch.

Staff and Headquarters.—Bt. Lieut.-Col. H. Boulton, I.M.S.; Lieut.-Col. G. B. Irvine, I.M.S.; Col. A. E. Tate, A.M.S.; Major A. W. C. Young, I.M.S.; Lieut.-Col. H. O. B. Browne-Mason, R.A.M.C.; Col. P. Hehir, C.B.

Royal Army Medical Corps.—Temp. Capt. R. M. Allan; Major E. V. Aylen; Capt. A. S. Cane; Capt. E. G. S. Cane; Capt. F. H. M. Chapman; Lieut.-Col. (temp. Col.) D. J. Collins; Major H. J. Crossley; Capt. F. T. Dowling; Capt. R. W. Duncan, Special Reserve (killed); Major J. G. Foster; Capt. H. L. Garson, Special Reserve; Capt. A. Glen, Special Reserve; Capt. W. T. Graham; Lieut.-Col. S. F. St. D. Green; Lieut.-Col. J. Hennessy, C.B.; Temp. Capt. A. J. Ireland; Capt. S. W. Kyle; Major F. C. Lambert (deceased); Lieut. W. G. Macdonald; Temp. Capt. A. N. Minns; Capt. T. J. Mitchell; Capt. W. H. O'Riordan; Capt. T. E. Osmond; Lieut.-Col. F. J. Palmer; Bt. Col. J. M. Sloan, D.S.O.; Capt. J. Stanton; Temp. Lieut. J. B. Thackeray; Capt. R. T. Vivian; Capt. H. F. Warwick; Capt. P. A. With.

Indian Medical Service.—Capt. A. R. S. Alexander (died of wounds); Bt. Lieut.-Col. S. Anderson; Capt. D. Arthur; Major E. F. E. Baines; Temp. Lieut. U. N. Banerjee; Major C. H. Barber; Major R. J. Bradley; Temp. Lieut. J. P. Cartevalla; Capt. R. C. Clifford; Major F. P. Connor; Capt. F. C. Fraser; Capt. D. C. V. Fitzgerald; Major W. Gillitt; Major C. M. Goodbody, D.S.O.; Capt. E. S. Goss; Capt. P. D. Green-Armytage; Capt. W. H. Hamilton; Capt. R. de S. B. Herrick; Capt. J. H. Hislop; Major J. H. Horton, D.S.O.; Capt. J. W. Jones; Major R. Kelsall; Capt. E. W. O'G. Kirwan; Capt. L. A. H. Lack; Major R. A. Lloyd; Capt. R. F. D. Macgregor; Major N. W. Mackworth; Capt. J. S. S. Martin; Lieut.-Col. A. H. Nott; Major W. S. Patton; Lieut.-Col. E. L. Perry; Capt. M. L. Puri; Capt. Rai Dewan Hakumat; Capt. H. K. Rowntree; Major C. O. C. Shaw; Capt. J. A. Sinton, V.C.; Capt. R. Sweet; Temp. Lieut. S. D. Sondhi; Lieut. W. C. Spackman; Capt. R. T. Wells; Bt. Col. W. W. White, C.B.; Capt. Sen Jyoti Lal.

DEATHS AMONG THE SONS OF MEDICAL MEN.

The following sons of medical men must be added to our lists of those who have fallen during the war:—

Second Lieut. T. S. H. Schäfer, 13th Northumberland Fusiliers, younger son of Sir E. Schäfer, F.R.S., of Edinburgh University.

Lieut. C. H. Brew, Irish Guards, younger son of Dr. R. H. Brew, of Chew Magna, Somerset.

Major R. E. E. Kriekenbeek, Indian Army, second son of the late Dr. C. A. Kriekenbeek, of Colombo, Ceylon.

Second Lieut. S. M. Williams, Sherwood Foresters, only son of the late Dr. R. H. Williams, of Pembroke Dock, South Wales.

Second Lieut. A. L. Menzies, Royal Field Artillery, youngest son of the late Surgeon-General Menzies.

Second Lieut. W. G. Boyd, Inniskilling Fusiliers, only son of Dr. J. C. Boyd, of Lifford, Co. Donegal.

Second Lieut. H. N. Heyward, Durham Light Infantry, third son of Dr. H. Heyward, of South Croydon.

Lieut. F. H. King, West India Regiment, attached West Riding Regiment, elder son of Colonel W. G. King, C.I.E., I.M.S. (retired), of Hatch End, Pinner, Middlesex.

L. A. Seccombe, youngest son of Dr. S. H. Seccombe, of Melbourne, Australia.

Lance-Corpl. W. M. Chapman, London Regiment, second son of Dr. C. W. Chapman, of Harley-street, London.

C. S. Nicholson, New Zealand Machine Gun Co., younger son of Lieut.-Col. J. E. Nicholson, R.A.M.C., of Winchester.

Lieut. J. H. Cameron, Black Watch, son of Dr. A. Cameron, of Dollar, Clackmannanshire.

Lance-Corpl. C. G. Webb, Royal West Kent Regiment, elder son of Dr. C. Webb, of Margate.

Capt. E. P. Wallis, attached Royal Sussex Regiment, son of Dr. P. E. Wallis, of East Grinstead.

OBITUARY OF THE WAR.

GERARD PRIDEAUX SELBY, B.A., M.B., CH.B. OXON.,
CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain G. P. Selby, who was killed on active service on Sept. 26th at the age of 25, was the eldest son of Dr. Prideaux Selby, of Teynham. Educated at Winchester and New College, Oxford, he completed his medical studies

at St. Bartholomew's Hospital, taking his M.B., Ch.B. Oxon. in 1914. At Oxford he was moving spirit in the Officers Training Corps, and later in London he joined the Inns of Court Officers Training Corps, in which he held the rank of sergeant when he passed into the Royal Army Medical Corps in July, 1914, just before war broke out. After six months' service he was promoted to captain, and he used to say that he had been private, corporal, sergeant, lieutenant, and captain all

within a little more than a year. He was first employed in training Royal Army Medical Corps men at Aldershot, and then went out as regimental medical officer to the Argyll and Sutherland Highlanders. He was wounded in the thigh in March, 1915, and after a period as member of a medical board for examining recruits he went out again attached to a field ambulance and later to a battalion of Lancashire Fusiliers. With them he met his death while attending to the wounded in the firing line.

Captain Selby, whilst keen on his medical work and possessing powers of concentration which enabled him to pass his examinations in the minimum time, was also an athlete. At Oxford he rowed as a freshman in the New College Torpids Eight, and he was a useful hockey player at back. His keenness impressed all those with whom he was brought in contact, and the organisation of his aid-post for the advance during which he lost his life was the subject of approving comment by his commanding officer.

JOHN DEIGHTON, B.A., M.B., B.C. CANTAB.,
CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain J. Deighton, who died of wounds contracted on active service on Sept. 19th, 1916, aged 29, was the third son of Lieutenant-Colonel Deighton, R.A.M.C. (T.), of St. Bernard's, Cambridge. He was educated at St. Faith's Preparatory School, Cambridge; King's School, Canterbury, where he was a scholar; and Trinity College, Cambridge, entering the London Hospital in January, 1912. He took the Conjoint Board qualification in October, 1913, afterwards holding various appointments at the hospital, and qualifying M.B., B.C. Cantab. the following year. In November, 1914, he obtained a commission in the R.A.M.C., and joined the special reserve of officers. In March of the following year he went to France with the 18th General Hospital, and in June was attached as medical officer to the King's Own Royal Lancaster Regiment, with which he met his death.

Captain Deighton was good both at work and play. At Cambridge he rowed, while he played forward for his College Rugby fifteen, and was a member of the London Hospital team which won the hospitals' cup at Richmond in March, 1914. His personal qualities made him popular among the officers and men of his battalion.

MAURICE PATERSON INGLIS, M.B., CH.B. EDIN.,
CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain M. P. Inglis, who was killed in action on Sept. 17th in his twenty-fifth year, was the second son of the Rev. William Balfour Inglis, B.D., of Valparaiso, and

a grandson of Maurice Paterson, LL.D., formerly rector of Moray House Training College, Edinburgh. He was educated at George Watson's College, Edinburgh, entering Edinburgh University, where in 1914 he graduated as M.B., Ch.B. At the outbreak of the war he held a lieutenant's commission in the Royal Army Medical Corps (Special Reserve), and in February, 1915, he went to the front, and towards the close of that year became a captain, having been mentioned in despatches. He met his death while attending to the wounded after a great advance.

Captain Inglis took a keen interest in athletics. At the Scottish Inter-University sports he represented Edinburgh University on several occasions, and was a good high jumper, being runner up in the Scottish high jump championship immediately before the outbreak of the war. He had considerable facility with the pencil, and his cartoons in the *Student* were enjoyed by his teachers and fellow students, with both of whom his frank

and genial disposition made him a general favourite. A letter from the colonel of his regiment speaks of the affection which these qualities produced for him among men and officers at the front. "He was keen and efficient, and always the first to go to the aid of wounded without thought for himself."

THE GARDELEGEN CAMP.

The report on the typhus epidemic at the Gardelegen camp, which has just been issued by the Government Committee on the treatment of British prisoners of war (Wyman and Sons. Cd. 8351. Price 1½d.), based on information provided by three officers of the Royal Army Medical Corps who were there—Major P. C. T. Davy, Captain A. J. Brown, and Captain A. Scott Williams—affords a close parallel to the conditions existing at the same time at Wittenberg. The camp was opened in November, 1914, on an area 350 by 550 yards, and was designed to hold 14,000 prisoners, of whom each company of 300 occupied a hut with about 6 cubic metres space per man. Each hut contained in its breadth four rows of straw palliasses arranged so that laterally they were touching and at the ends only the narrowest passage-way was left between. In February, 1915, the camp contained about 4000 Russians, 6000 French, 700 Belgians, and 230 British, the latter, although relatively few in number, being, by official instructions, mixed in proportionate numbers in each barrack-room. The diet consisted of soup, black bread, and a weekly raw herring, and, until supplemented with supplies sent from home, was so insufficient that the Russian prisoners struggled in the refuse-pit for potato-parings. The men were inadequately clothed: most of the British prisoners had no overcoats, nearly one-half had no boots. The sufferings engendered by insufficient food and clothing were aggravated by the extreme cold of the winter 1914-15, as although two fire-places were provided in each hut, the fuel was quite insufficient. A latrine and urinal were provided for each company under one roof, and the task of emptying the latrines into the tank cars was allotted to the British prisoners until their numbers were too much reduced by sickness to provide a fatigue party of sufficient strength. The water-supply was sufficient, but prior to the outbreak of typhus there were practically no facilities for personal cleanliness; a trough in each compound served for washing person, clothing, and utensils, all entirely without soap. Lice, therefore, swarmed in every garment worn and in all the bedding. The result of these privations was to reduce all the prisoners to a condition of apathetic misery in which their chief occupation was the killing of parasites. At the beginning of February two British medical officers, four French, and four Russians were brought into the camp,

apparently in anticipation of an epidemic, and a few days afterwards, the sickness-rate having mounted to 50 a day, the German medical officer, with his assistant and staff of nursing orderlies, evacuated the camp along with all the German guards, who then formed a cordon around it. The sick were thus left entirely unattended until the imprisoned medical officers devised a complete invalid service. Among the 11,000 prisoners, 2000 cases of typhus occurred, which was fortunately of a milder type than at the other German camps. An epidemic of scarlet fever occurred at the same time. 12 of the 16 doctors in the camp contracted typhus and 2 died. Of the 22 British soldiers who volunteered as orderlies 20 caught typhus and 2 died. No milk was supplied by the German authorities, but the medical officers succeeded in obtaining a supply from the town, which they paid for themselves. Drugs and dressings were scanty, and neither bed-pans nor urinals were available for the sick. With the advent, however, of an elderly German medical officer in civilian dress, towards the end of March, matters began to improve, and finally a large bath-house with disinfectant was installed, but only when the epidemic was spent. The report bears suitable testimony to the splendid work of the British medical officers under circumstances of appalling difficulty. Two have now returned to this country, but Captain Scott Williams still remains, although not at Gardelegen, which no longer contains any British prisoners. The facts of German camp administration speak for themselves; the Committee records its belief that these methods are typical of German prison administration.

CHRONIC DISEASE AND MILITARY FITNESS.

A recent Army Council Instruction in regard to surgical operations for certain conditions seems to have given rise to some misunderstanding. The instruction is confined to those diseases which existed before the war, and which do not render a man unfit for military service. It has been brought to the notice of the authorities that a large number of surgical operations are being performed for chronic conditions which existed previous to joining the Army, and which do not render a man unfit for military service, whereas the operations have frequently been found to render the officer or man unfit for long periods. It is rightly suggested that such operations should not be performed unless there is very good reason to believe that the disability is one which unfits the patient for military service, and that the result of the operation will be speedy restoration to military fitness. The operations referred to include those for certain forms of varicocele, hernia, and chronic nasal conditions, chronic pyorrhoæa, chronic enlargement of the tonsils, flat-foot, deformities of the toes, and chronic abdominal conditions. These instructions will prevent the occupation of beds more urgently required for the sick and wounded returning from the front.

AUXILIARY R.A.M.C. FUNDS.

The following list of donations, totalling just over £731, has been received for the Officers' Benevolent Branch up to Oct. 6th:—

"From a Friend" (per Sir Wm. Osler) £100; Lieut.-Col. W. Collier, Major W. F. Brook, and Lieut.-Col. W. Hale White, each £52 10s.; Lieut.-Col. H. C. Barling, £50; Lieut.-Col. F. W. Westmacott and Major Ewen Maclean, each £21; Major A. C. Farquharson, £20; Capt. A. A. Young, £15; Capt. Hugh F. Wickens, Lieut.-Col. Sir James Barr, Lieut.-Col. Geo. S. Middleton, Capt. Cholmondeley Webb, Major T. K. Monro, Major T. W. Buckley, Capt. Hugh H. Weir, and Lieut.-Col. T. Gowans, each £10 10s.; Surg.-Gen. Sir G. H. Makins, K.C.M.G., C.B., Capt. D. Douglas Crawford, and per Sir William Osler, each £10; Col. Sir J. Rose Bradford, K.C.M.G., C.B., Col. W. Coates, Lieut.-Col. G. A. Bannatyne, Lieut.-Col. Norman Dalton, Capt. Edgar Grey, Capt. V. Rich, Capt. E. F. Buzzard, Capt. H. R. Vachell, Lieut.-Col. Claude Douglas, Capt. R. P. Rowlands, Lieut.-Col. W. F. Haslam, Capt. W. B. Warrington, Capt. A. Blackwell, Lieut.-Col. B. L. Hamilton, Surg.-Col. Atwood Thorne, V.D., Major H. H. Littlejohn, Lieut.-Col. W. Pasteur, Major D. W. Patterson, Major J. W. Leech, Lieut.-Col. W. G. Richardson, Capt. F. W. Wilson, Lieut.-Col. A. M. Martin, Lieut.-Col. H. B. Angus, Dr. A. Duke, Major J. D. Wardale, Major A. Parkin, Major R. P. R. Tyle, and Lieut.-Col. T. Beattie, each £5 5s.; Col. D. J. Mackintosh, M.V.O., Capt. H. H. Kendrick, Capt. H. Gordon Oliver, Capt. H. H. Elliot, Lieut.-Col. H. P. Hawkins, and Lieut.-Col. W. F. Roe, D.S.O., each £5; Capt. Ed. Mackay and Lieut.-Col. Mansell Moullin, each £4 4s.; Capt. T. V. Mills, Capt. Leslie H. Walsh, Lieut. A. P. Gibbons, Lieut.-Col. R. A. Bolam, Capt. T. H. Livingstone, Major F. C. Pybus, Major W. D. Arnison, Capt. H. J. Slade, and Capt. W. T. Harkness, each £3 3s.; Capt. V. H. Blake, Major G. Newton Pitt, Capt. C. E. Droop, Capt. Robert Thompson, Capt. W. Seymour, and Capt. C. F. Armstrong, each £2 2s.; Capt. W. B. Courlay, £2; Major T. S. Toogood, Major W. W. Jones, Capt. Slater, Capt. Menzies, Capt. Lickley, Lieut. P. E. Murray, Lieut. H. O. Wheeler, Lieut. W. B. Anderson, and Lieut. and Qmr. Gibbs, each £1 1s.

ITALY'S "MUTILATI" AND "STORPI."

Our Italy correspondent writes as follows:—Turin, the seat of the great sub-Alpine medical school, has for well-nigh a year been solving the difficult problem of converting the cripples of the war into bread-winning citizens, first by surgical and orthopaedic methods, and next by "re-education" in this or that handicraft, for which special laboratories have been instituted where handicraft or *métier* may be acquired. The Order of Rosmini, for instance, now accommodates more than 100 "mutilati," who are learning to be shoemakers, tailors, bookbinders, accountants, typewriters, telegraph clerks, &c., and its example will soon be followed by other institutions with laboratories specially equipped for the acquisition of other *métiers*. The undertaking is an uphill one in Italy, where the greater number of cripples are peasants with little more than an elementary schooling; but the progress made is reassuring. Much more difficult, however, is the re-education of the "storpi" or functionally impaired. Conservative surgery reduces the number of the "mutilati"; but the "storpi" are much less easily dealt with, besides being more numerous, their numbers being 7000 as against 4000 cripples. There are men who have sustained traumatic lesions of peripheral nerves whose function is thereby, directly or indirectly, paralysed.

A subject may have to be treated with an arm pendulous, so as to be practically an extraneous body; we meet another whose arm is "materially" normal, but in such a state that it can neither be raised nor applied to any use, the man is in fact a "mutilato." Others come before you with a hand normally articulated but with the fingers sensorially dead, or immovable; others again have the joints ankylosed or so stiff that the limb has lost its function. The list of similar cases might be extended indefinitely, including lesions, which, compatible with existence, or even with partial use, or confined to a limited part of the body, leave the subject with a sense of supine resignation to partial deformity, rather than submit to a surgical operation, not severe in itself, but capable of curing him. This happens often enough in the case of the imperfectly educated subject, while equally often he has not the means or the opportunity of resuscitating the suspended function. Many of these "storpi" have been sent to provincial hospitals, where the apparatus for physiotherapeutic treatment is non-existent. How many return home for fear that the resuscitating of the function of the limb may deprive them of the compensation allowed them by the State we wonder.

In France, and lately in England, a great impulse has been given to neurological studies dealing with the case of the "storpi," and admirable indeed is the perfection they have reached in diagnosing and in localising lesions of individual nerves. (I learn this from the columns of French and English papers, both medical and lay.) In Italy such progress is but partially in evidence; though something has already been achieved. There is, for example, the Villa Bondi at Florence, superintended by the nerve specialist, Professor Ettore Levi, where, from the outbreak of the war, the scientific treatment of the "storpi" has been creditably carried out. At Milan, in the neurological department of the "Ospedale," Professor Meda has done good work in this direction; and quite lately from Pavia Professors Sala and Verga have issued a monograph, based on their experiences in the Hospital of the Collegio Borromeo (directed by Camillo Golgi, of antimalarial fame), experiences of signal success in treating the lesions inflicted by firearms on the peripheral nerves. At Turin the military authorities and the civil authorities have already recognised and attempted to carry out the indicated treatment. At the Ospedale Mauriziano, at the Central Military Hospital, and at the San Giovanni Hospital, such treatment has, in part, been initiated. But there is still a want, even in Turin, of a regular neurological department in which a specialist can give his undivided attention to the whole subject, following out the approved methods, collecting all the clinical records illustrative of such cases, and the scientific-practical conclusions obtained at other institutions, foreign as well as Italian. For the filling up of such a want the Turinese school is making laudable efforts, inspired mainly by that veteran clinician and philanthropist Professor Pio Foa, to whose recent manifesto on the subject the reader is referred for data, for the statistics and arguments with which he reinforces his

propaganda are illuminating. True to traditions as the cradle of Italian unity and independence, the sub-Alpine capital cannot but respond to the appeal of its illustrious citizen and so furnish to its provincial, especially its southern, sisters an exemplar to be followed, if not improved upon, in relief of their country's sufferers.

THE SUPPLY OF MEDICINAL GLYCERINE.

As from April 1st, glycerine manufacturers were asked to obtain from buyers a guarantee that all medicinal glycerine delivered would be used only for making up British Pharmacopoeia or B.P. Codex preparations, or where it was prescribed in individual cases, either alone or in combination with other drugs, by a duly qualified medical practitioner. These restrictions were not applied to stocks of glycerine held by wholesalers or retailers prior to April 1st, but in view of the increased necessity for conserving the supply for the needs of the war, and of the possibility that it may be necessary to reduce still further the quantity to be allowed for medicinal purposes, holders of such stocks are now asked to apply the restrictions to them. Such action will directly serve national interests in tending to secure a sufficient supply of glycerine for the general public in those cases where its value for medicinal purposes is of importance.

THE PROBLEM OF THE WAR CRIPPLE.—Sir Alfred Keogh presided last week at a meeting of the Association of Technical Institutions called to consider the problem of training disabled men from the services for useful occupations. He stated that he had long been of the opinion that no movement for this training would be successful unless it had the cooperation of the heads of the technical institutions, and these institutions must be intimately associated with the hospitals. It was true that the Army Council were making arrangements to establish workshops for curative treatment in connexion with the orthopaedic hospitals and dépôts up and down the country, and the opportunity could then be taken of starting the training of men in certain industries. But, he said, the primary object of the hospitals was to get men back to the ranks, and the training of the men unfit for further service must be carried out after their discharge through some such agency as the Association of Technical Institutions. The resources of the Army would be placed at the disposal of the discharged soldier for this purpose.

THE MANOR WAR HOSPITAL.—Mr. A. F. Buxton, chairman of the London County Council, writing from the County Hall, asks for extra comforts, such as books, fruit, stationery, tobacco, and sweets, for the 1200 sick and wounded soldiers who will receive accommodation in the London County Council Manor Asylum, which has been taken over by the War Office. In addition to the gifts in kind which have already been received, personal help and £2000 are required in connexion with a canteen and lodgings for visiting friends. Mrs. A. F. Buxton is the almoner and Miss Constance Toynbee the secretary. The bankers are the Union of London and Smith's Bank. Gifts in kind will be warmly welcomed at the hospital, near Epsom station.

THE AMERICAN WOMEN'S WAR HOSPITAL AT PAIGNTON.—We have received the third report¹ of this hospital dealing with the third thousand cases treated there. The total number of wounded men treated was 359, of whom 205 had pyrogenic infections, 7 an infection with the gas bacillus, 1 with tetanus, 3 with erysipelas. Only 6 amputations were performed, 1 of the thigh, 5 of fingers. Under infectious medical conditions were treated 45 cases of bronchitis, 32 of rheumatism, 16 each of pneumonia and endocarditis, 15 of influenza. Of non-infectious conditions, debility was credited with 56, nephritis with 36, emotional shock with 19, and gas poisoning with 14. Death occurred in 4 cases, 3 surgical and 1 pneumonia. The average stay was 33.4 days. Fifty-eight men were invalided out of the service, 104 were transferred elsewhere for special treatment, 415 to convalescent homes, and 419 to furlough, 10 days being granted for all except enteric cases who are given six weeks. A new massage and electrical department was opened on May 18th, and has given treatments as follows: Massage, 813; electrical, 383; ionisation, 273; and radiant heat, 114. The staff now includes besides the chief surgeon, Dr. Pearce

Penhallow, Dr. H. M. Frost, principal assistant surgeon, Dr. A. J. Casselman, pathologist, and three assistant surgeons.

ROYAL PORTSMOUTH HOSPITAL.—In response to an application from the Assistant Director of Medical Services, Portsmouth, for 60 additional beds for the wounded, the committee of the Royal Portsmouth Hospital, anxious to assist the military in every way consistent with the interests of the civil population, have decided to offer the present out-patients' department and another ward for that purpose. If the proposal is accepted it will necessitate some alterations; the expenses will, it is presumed, be borne by the War Office.

AN AUXILIARY V.A.D. HOSPITAL AT NORWOOD.—Lady Londonderry has opened the Lambeth Auxiliary V.A.D. Hospital at "Homedale," The Avenue, Upper Norwood. The building, which has been lent by Colonel and Mrs. Sleeman, contains 40 beds.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates were successful:—

Surgery.—H. St. H. Vertue (Sections I. and II.), Oxford and Guy's Hospital.

Medicine.—W. Burridge (Section II.), Oxford and Guy's Hospital; R. F. Jarrett (Section II.), London Hospital; O. A. Mortlock-Brown (Section II.), Royal Free Hospital; R. H. Pettersson (Section I.), St. George's Hospital; M. M. Shafi (Sections I. and II.), London Hospital; I. H. Syed (Sections I. and II.), Bombay and Manchester; S. L. Szpligner (Section II.), London Hospital; S. C. Varley (Sections I. and II.), Oxford and St. George's Hospital; and A. G. E. Wilcock (Sections I. and II.), Cambridge and St. George's Hospital.

Forensic Medicine.—S. C. Ho, Cambridge and London Hospital; and W. Stansfield and B. Walley, Manchester.

Midwifery.—D. D. Hearn, Durham.

The diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—

W. Burridge, R. F. Jarrett, S. C. Varley, and H. St. H. Vertue.

EXAMINING BOARD OF THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH AND ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—The following are the results of the Triple Qualification Examinations:—

FIRST EXAMINATION.

Pauline Figlor, Andrew Gold, Arthur William Hodder Noble, John Murray, and Thomas Hall James Douglas.

Physics.—Sayed Ghaleb, Demetrius Maurice O'Flaherty, and John Leo King.

Biology.—Demetrius Maurice O'Flaherty and Eric Edward Macpherson Steen.

SECOND EXAMINATION.

Joseph Black, Jane Copas, H. A. Madman, Jacob Johannes Van Niekerk, Andre Antoine Lamsletle, Jung Bahadur Singh, and Joseph Campbell.

Anatomy.—Alexander Forayth Caddell, James Charles Meek, and Andrew Wood Smith.

Physiology.—Thomas Richard O'Keefe, Thomas Francis Kelly, and Thomas Hall James Douglas.

THIRD EXAMINATION.

Bliza Jean Stuart, John Bourke, Albert Ernest Hempleman, Thomas Lloyd Edwards, Hugh McIlroy, Arukatti Patabendige Frederick Abeyuriya, Harold Gengoult Smith, Robert Pollock, and Albert Sandelson.

Pathology.—Andrew Francis Brigmen and Albert Herbert Brooke Hudson.

Materia Medica.—Hugh William Howatson, Arthur Stanley Hughes, Richard Gordon Bell, and Reginald Leslie Wright.

FINAL EXAMINATION (L.R.C.P. & S. EDIN., L.R.F.P. & S. GLASG.).

Reginald John Thomas Malcolm-Gasper, Spearman Charles Swinburne, William John Mitchell White, Edgar Annequin, Stanley Wall Hoyland, Martha Hunter Hoshing, Charles George Booker, Herbert Ainslie Grant Dykes, Janie Isabel McBurnie, Edward Mervyn Lewis Morgan, Paul Lucien Manuel, Harry Morley, Reginald Vincent Clarke, Robert McGregor, Owen Glendower Evans, Edwin Butler, and Robert Woodside.

Medicine.—Yeshwant Narayan Kadam, Edward Glyn Jones, William Fuller Mason, and John Joseph Mulvey.

Midwifery.—Yeshwant Narayan Kadam, William Fidler Mason, Russell Neilham Burton, and Wendell Thomas Garretson.

Medical Jurisprudence.—Cecl Vale Samwell, Indranarayan Borrah, William Clie Desmond Longford, George Nicol Groves, Thomas Robert Wilson, Henry Shaw, Don Adrian Jaysinghe, Robert McLaren, Patrick Aloysius O'Brien, and Wendell Thomas Garretson.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—At a meeting of the College held on Oct. 19th, the following gentlemen having passed the requisite examinations between July 3rd and 5th, were admitted Fellows:—

Matthew Leslie Guy Hallwright, M.R.C.S., L.R.C.P. Lond. M.D. Durh., Captain, New Zealand Medical Corps; Maurice Horan,

¹ The first report was noticed in THE LANCET of Oct. 23rd, 1915, p. 949, and the second on Feb. 12th, 1916, p. 380.

M.B., B.Ch. Dub., Great Northern Central Hospital, London; William Outhbert McGaw, M.B., Ch.B. New Zealand, Captain, New Zealand Medical Corps; James McHoul, M.B., B.S. Glasgow, Captain, R.A.M.C. (T.); John Daniel Milne, M.B. Toronto, M.R.C.S., L.R.C.P. Lond., Lambeth, Ontario, Canada; Hamish Nicol, M.R.C.S., L.R.C.P. Lond., London; Arthur Charles Oldham, L.R.C.S. Edin., Major, R.A.M.C. (T.), Kildermister; and George Lionel Preston, M.R.C.S., L.R.C.P. Lond., Saltash, Cornwall.

ROYAL SOCIETY OF MEDICINE.—Before the Section of Surgery on Oct. 31st, at 5 P.M., Dr. Sherman, of Pittsburg, U.S.A., will deliver a lecture on the "Sterilisation of Wounds by the Method of Carrel," with epidiascope demonstration.

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL (UNIVERSITY OF LONDON).—The University Scholarship in Anatomy and Physiology has been equally divided, and awarded to L. M. Moody and H. T. Rymer.

LONDON HOSPITAL MEDICAL COLLEGE (UNIVERSITY OF LONDON).—Entrance Scholarships in Science have been awarded as follows: "Price" Science Scholarship (value £100), R. A. Madgwick; Entrance Scholarship in Science (value £50), D. Hunter.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—Dr. Hector Mackenzie will deliver the Bradshaw lecture on Exophthalmic Goitre on Nov. 2nd; Dr. H. R. Dean the Horace Dobell lecture on the Mechanism of the Serum Reactions on Nov. 7th; and Dr. W. H. R. Rivers the FitzPatrick lectures on Medicine, Magic, and Religion (Part II.) on Nov. 14th and 16th. The lectures are open to all members of the medical profession, and begin in each case at 5 P.M.

THE LATE DR. OLIVE CLAYDON.—In the brief notice of the career of Dr. Olive Claydon which appeared a fortnight ago it should have been mentioned that it was principally due to her initiative that the Friendly Societies decided to modify their regulations so as to allow patients incapacitated for work by venereal disease to receive sickness benefit.

WAR GRANT TO PANEL CHEMISTS.—An additional war allowance of 0.3d. per prescription has been granted to panel chemists by the National Health Insurance Joint Committee for the year 1917, as well as retrospectively for the whole of the year 1916, conditional upon a satisfactory pharmaceutical service being secured for the coming year.

Mr. Frank Kidd, assistant surgeon to the London Hospital, will deliver a course of lectures on "Diseases of the Male Urethra" in the clinical theatre of the hospital on Mondays, Nov. 13th, 20th, 27th, and Dec. 4th, at 4 P.M.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Sale of Cocaine.

A LARGE number of Members of the House of Commons have placed on the notice paper the following motion: "That in the opinion of this House the special permit granted by the Secretary of State for the Home Department to unregistered practitioners in dentistry to purchase and use solutions containing not more than 1 per cent. of cocaine for the purposes of local anaesthetics up to Oct. 31st, 1916, should be extended for a further period of six months."

Medical Men Serving as Combatant Officers.

Mr. FORSTER, Financial Secretary to the War Office, has now stated in the House that any hardship arising in the case of a medical man serving as a combatant officer will receive his consideration.

HOUSE OF COMMONS.

WEDNESDAY, OCT. 18TH.

Alcohol in Military Hospitals.

Major CHAPPEL asked the Financial Secretary to the War Office whether, in view of the fact that Guy's Hospital had reduced the cost of alcohol administered to patients from £1576 per annum to £151, Leeds Infirmary from 6s. 6d. per head per annum to 2d., and Wandsworth Infirmary from 5s. 3d. per head per annum to one-half of 1d., he would cause inquiry to be made as to whether the mortality or length of time in hospital had in these institutions increased in consequence, in order that the War Office might be in a position to advise military hospitals, in the interest of economy, rapid convalescence, and the ultimate sobriety of our men.—Mr. FORSTER wrote in reply: Economies in the issue of stimulants and of all other hospital supplies have been receiving the careful attention of a special committee under the presidency of Major Godfrey Collins, M.P., and the amount of alcohol is limited to what is medically necessary.

Price of Milk.

Answering Mr. SUTTON, Mr. PRETYMAN (Parliamentary Secretary to the Board of Trade) said: I am in agreement with the views expressed by speakers who represent agricultural interests, that the increases in the expenses of dairy farming have not been so great as to justify a contract price for milk higher than 1s. 4d. per imperial gallon at the London stations and corresponding prices in other large towns. Outside the large towns prices should be on a lower level than this. The possibility of taking steps to secure a limitation of price to this figure without reducing the supply of milk is engaging the careful attention of the Board of Trade and the Board of Agriculture. It is hoped that dealers will succeed in resisting demands for higher prices in any purchases that remain to be made. In any case it is proposed to take immediate steps by legislation, if necessary, to carry out the recommendation of the Departmental Committee on Prices to obtain information as to milk contracts and the prices paid.

Medical Treatment of Discharged Soldiers.

Mr. NUGENT asked the representative of the National Insurance Commissioners what arrangements, if any, were made for the treatment of discharged sailors and soldiers who were insured persons in the United Kingdom; and, in view of the fact that medical benefit did not apply to Ireland, would he make arrangements with either the Irish Insurance Commission or Approved Societies and empower them to make the necessary arrangements for discharged and disabled sailors and soldiers to receive the necessary medical treatment.—Mr. C. ROBERTS wrote in reply: In Great Britain these men receive medical benefit under the ordinary arrangements. As regards Ireland, the matter is one which concerns primarily the Statutory Committee on Pensions, who are carefully considering the matter.

THURSDAY, OCT. 19TH.

Invalid Civilian Prisoners in Britain and Germany.

Answering Mr. MALCOLM, Mr. FORSTER said: As the transfer of German invalid civilians interned in this country to Switzerland would be a matter of considerable difficulty, a scheme is now under consideration for the mutual repatriation of such invalids from this country and Germany on somewhat the same lines as to the method of selection and schedule of invalidity as now obtain for the transfer of combatant prisoners of war to Switzerland.

Medical Treatment of Disabled Sailors and Soldiers.

Mr. HOGGE asked the Parliamentary Secretary to the Local Government Board whether he could give the House the text of the agreement drawn up between the Statutory War Pensions Committee and the Insurance Commissioners for a scheme of medical treatment, including specialist advice, for all disabled sailors and soldiers.—Mr. HAYES FISHER replied: As the scope of the agreement and its terms are not yet finally settled, I fear it is not possible for me to comply with the suggestion in the question.

T.N.T. Poisoning.

Answering Lord HENRY CAVENDISH-BENTINCK in regard to two deaths of female munition workers from T.N.T. poisoning, Mr. BRACE (Under Secretary for the Home Department) wrote: The Home Office has received reports with regard to these two cases. In the case of one of the women, who was not an employee of the firm but an examiner sent to the works on behalf of the Government, the usual precautions had, through a misunderstanding as to her position, not been carried out. In the other case also the doctor appointed for the factory, although a full-time officer, had not been able, owing to the amount of work to be done, to carry out the full periodical examination of the workers. Both defects have now been remedied. The question of T.N.T. poisoning is receiving the close attention of the Home Office and the Ministry of Munitions, and special measures have been taken for dealing with it. Further modifications of the regulations are under consideration. The problem is a new one, and is made more difficult by the fact that the manufacturing processes are constantly being modified. The precautions which are now required or under consideration include all the measures which the experience so far obtained suggests, and further investigations and experiments with new methods and appliances are being made.

TUESDAY, OCT. 24TH.

The Sale of Cocaine.

Mr. RAFFAN asked the Under Secretary for the Home Department how many prosecutions had taken place for violation of the Order in Council prohibiting the sale of cocaine for improper purposes; and in how many cases, if any, the source of supply had been traced to dental practitioners, either registered or unregistered.—Mr. BRACE replied: There have been 25 prosecutions in the metropolitan police district for the violation of this Order in Council. In none was the source of supply traced to a dental practitioner. I have no information as to the number of prosecutions outside the metropolitan police district.

Experiments on Living Animals.

SIR GEORGE GREENWOOD asked the representative of the National Insurance Commissioners whether the experiments upon living animals with chlorine gas performed by Dr. Flack in the laboratory of the Medical Research Committee between July 2nd and 22nd, 1915, were paid for by moneys provided by Parliament out of the general taxation of the country under the National Insurance Act; whether his attention had been called to the nature of these experiments; whether such experiments were correctly described in the annual returns as experiments in the nature of simple inoculations, hypodermic injections, and similar proceedings, and as experiments not involving a serious operation; whether they were performed under a scheme of medical research prepared by the Medical Research Committee under the National Insurance Act; and whether he would lay a copy of any such scheme upon the table of the House.—MR. CHARLES ROBERTS (in a written answer) replied: The answers to the first, second, and third paragraphs of the question are in the affirmative. In reply to the fourth paragraph, I may say that schemes approved by the chairman of the Joint Committee under Section 7 (1) of the Regulations would not include details of the particular manner in which, or the particular experiments by help of which, a given scheme of research is to be carried out. In the present case the work was sanctioned as a piece of research which was necessary for the solution of certain medical questions of immediate national urgency in the war conditions of July, 1915, but which was also likely to produce knowledge of the greatest value in medical work for the civil population. In reply to the fifth paragraph, I would refer the honourable Member to paragraph (f) on p. 20 of the report of the Committee for 1914-15 presented to Parliament last year.

T.N.T. Poisoning;

MR. ROWLANDS asked the Under Secretary for the Home Department whether his attention had been called to two inquests on women who died of T.N.T. poison; could he say how many deaths from the same cause had occurred during the past three months, and what action was being taken to prevent these disasters.—MR. BRACE replied: The Home Secretary's attention has been called to both these cases. During the quarter ending Sept. 30th the number of reported deaths from the same cause was 21. The Home Office and the Ministry of Munitions are taking every possible step to investigate and deal with this new source of danger.

WEDNESDAY, OCT. 25TH.

The Sale of Cocaine.

MR. RAFFAN asked the Home Secretary whether it was in contemplation to extend the general permit enabling unregistered practitioners in dentistry to obtain solutions containing not more than 1 per cent. of cocaine for purposes of anaesthetics beyond Oct. 31st; and, if so, to what date.—MR. H. SAMUEL replied: I have promised to appoint a small committee to make further inquiries, pending which the temporary permits issued to unregistered dental practitioners will be extended.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

- ADAMS, ALFRED, M.B., B.Ch. Oxon., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health for Looe (Cornwall).
COLCLOUGH, W. F., M.D. Cantab., Certifying Surgeon under the Factory and Workshop Acts for the Sidmouth District of the county of Devon.
GLEN-BOTT, M., M.R.C.S., L.R.C.P., and PARKINSON, K. H., M.R.C.S., L.R.C.P., House Surgeons to the Royal Free Hospital.
KRUK, Malame, M.D., Assistant Anaesthetist to the Royal Free Hospital.
MACKAY, HELEN M., M.B., B.S. Lond., and MATLAND, A. M., M.R.C.S., L.R.C.P., House Physicians to the Royal Free Hospital.
PRING, C. H., L.S.A., to serve as a Medical Practitioner upon the Insurance Committee for the County of London.
SMITH, MIALI, M.R.C.S., L.R.C.P., Senior Obstetric Physician to the Royal Free Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

When the application of a Belgian medical man would be considered the advertisers are requested to communicate with the Editor.

- BARNLEY, BECKETT HOSPITAL AND DISPENSARY.—House Surgeon Salary £250 per annum, with board, &c.
BRIMMINGHAM CITY EDUCATION COMMITTEE.—Temporary Assistant School Medical Officer. Salary £300 per annum.
BRISTOL ROYAL INFIRMARY.—House Physician. Salary at rate of £120 per annum, with board, &c.

- BURY INFIRMARY.—Senior House Surgeon. Salary £250 per annum, with board, &c.
CAMBRIDGESHIRE ASYLUM, Fulbourn, near Cambridge.—Junior Assistant Medical Officer, unmarried. Salary £200 per annum, with board, &c.
DUDLEY, GUEST HOSPITAL.—Senior Resident Medical Officer. Salary £150 per annum, with board, &c. Also Assistant House Surgeon, for six months. Salary £120 per annum, with board, &c.
HACKNEY METROPOLITAN BOROUGH.—Two Temporary Medical Officers for one attendance of two hours per week, in connexion with Council's Infant Welfare Centres. Salary at rate of 10s. per hour.
HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—House Physician for six months. Salary 30 guineas.
ISLEWORTH UNION INFIRMARY.—Temporary Assistant to Medical Superintendent. Salary £375 per annum, with rations, &c.
LEICESTER ROYAL INFIRMARY.—Pathologist to Infirmary and Venereal Diseases Section. Salary at rate of £500 per annum. Also Medical Officers in Charge of Clinics and Beds. Salary £200 for Male Officer and £150 for Female Officer. Also Vacancy on Resident Surgical Staff. Salary £250 per annum.
LONDON LOCK HOSPITAL (MALE), Dean-street, Soho, W.—House Surgeon for six months. Salary at rate of £150 per annum.
LYONS' RED CROSS HOSPITAL.—Assistant Surgeon. Salary 25s. per week and all found.
NEWCASTLE-UPON-TYNE AND NORTHUMBRIAND SANATORIUM FOR CONSUMPTIVES, Barrasford, North Tyne.—Resident Medical Officer.
NOTTINGHAM GENERAL HOSPITAL.—Two House Physicians and One Assistant House Surgeon for six months. Salary at rate of £250 per annum each, with board, &c.
PRESTON, LANCs. COUNTY ASYLUM, Whittingham.—Locum Tenens, unmarried. Salary £7 7s. per week, with board, &c.
ROYAL FREE HOSPITAL, Gray's Inn-road, W.C.—Dental Surgeon.
SALFORD UNION INFIRMARY, Hope, Pendleton, near Manchester.—Female Assistant Resident Medical Officer. Salary £250 per annum, with board, &c.
SHEFFIELD, JESSOP HOSPITAL FOR WOMEN.—Female Junior House Surgeon, unmarried, for Gynaecological and Maternity Departments. Salary £200 per annum, with board, &c.
SHEFFIELD, ROYAL INFIRMARY.—Two House Surgeons. Salary £100 per annum, with board, &c.
SHEFFIELD UNION HOSPITAL, Firvale.—Resident Assistant Medical Officer. Salary £400 per annum, with rations, &c.
SOUTH LONDON HOSPITAL FOR WOMEN, 103, South Side, Clapham Common, S.W.—Female House Physician and House Surgeon for six months. Salaries at rate of £100 per annum, with board, &c. Also Temporary Female Assistant Physician to Children's Department.
VENTNOR, ISLE OF WIGHT, ROYAL NATIONAL HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST ON THE SEPARATE PRINCIPLE.—Assistant Resident Medical Officer.
WALSALL AND DISTRICT HOSPITAL.—Assistant House Surgeon and Anaesthetist. Salary £150 per annum, with board, &c.
WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—Resident Medical Officer for six months. Salary at rate of £150 per annum, with board, &c.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Valencia and Rathmore, in the county of Kerry.

Births, Marriages, and Deaths.

BIRTHS.

- DAVIS.—On Oct. 23rd, at Upper Berkeley-street, W., the wife of K. J. Aetion Davis, F.R.C.S., M.C.—a daughter.
NICHOLLS.—On Oct. 20th, at Wellesley Lodge, Croydon, the wife of Dr. G. E. E. Nicholls, Temporary Lieutenant, R.A.M.C.—a son.
PATTERSON.—On Oct. 20th, at Harley-street, the wife of Norman Patterson, F.R.C.S.—a daughter.

MARRIAGES.

- BYE-BRITTON.—On Oct. 21st, at the Chapel Royal, Savoy, Norman Huthance Bye, F.R.C.S.E., to Edith Mary, only daughter of the late George Britton, of Putney and Hastings.
DRENNAN-DUDGEON.—On Oct. 19th, at All Saints Church, Blackrock, Dr. Charles Edward Drennan to Rose, second daughter of Mr. and Mrs. Dudgeon, of The Priory, Stillorgan.
FRASER-ARMSTRONG.—On Sept. 14th, at the Cantonment Church, Melkita, Burma, Captain A. D. Fraser, R.A.M.C., to Emily Clara, only daughter of the Rev. W. D. H. Armstrong, Berrow Vicarage, Somerset.
SHERMAN-BROOKE.—On Oct. 23rd, at St. Alfege, Greenwich, Captain Reginald Sherman, R.A.M.C., to Dorothy Raffles, elder daughter of J. Raffles Brooke and Mrs. Brooke, Osborne House, Formby, Lancs.

DEATHS.

- THOMSON.—On Oct. 21st, at Lowestoft-road, Gorleston-on-Sea, David Thomson, L.R.C.P. & S. Edin., L.F.P.S. Glasg., aged 55.
WATERS.—On Oct. 14th, at Dorset-road, Bexhill-on-Sea, Avery Clough Waters, M.B., J.P., late of Whitegates, Southend-on-Sea, aged 54 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

The following journals, magazines, &c., have been received:—*Annales de l'Institut Pasteur*, *Journal of Comparative Pathology and Therapeutics*, *Journal of Laryngology, Rhinology and Otolaryngology*, *New Zealand Medical Journal*, *St. Mary's Hospital Gazette*, *Archives of Radiology and Electro-therapeutics*, *American Journal of Medical Sciences*, *American Journal of Obstetrics*, *American Journal of Surgery*, *Nordiskt Medicinskt Arkiv*, *British Journal of Children's Diseases*, *American Journal of Orthopedic Surgery*, *Saint Paul Medical Journal*, *American Medicine*, &c.

Notes, Short Comments, and Answers to Correspondents.

"AN IMPORTANT DISCLAIMER."

THE post remarked that "some men are born to fame, some men acquire it, and some have honours thrust upon them." Mr. Eustace Miles (M.A. Cambridge) has for many years been in the second class as a champion racket and tennis player and as the owner or conductor of a restaurant bearing his name. He is now, as we learn from a document which lies before us, the title of which we have borrowed, in the third class. To quote his own words, he "in view of the letters that he has received addressed to him as 'Dr. Eustace Miles,' wishes to make it clear—in order to prevent misunderstanding—that he is not a qualified Medical Practitioner; and that—while he appreciates at its true value the special training and hard work of the medical profession—he himself advises people rather as to simple methods of cure (through Diet, &c.) which most Doctors have not (like himself) studied and practised assiduously and effectively for years. He does not undertake to prescribe heavy doses of drugs nor to operate." His medical position has been thrust upon him.

We learn further from the "important disclaimer" that for a good many years Mr. Miles "has been professionally advising consultants (including qualified medical practitioners, who sometimes consult him about their own diet, or the diet of their patients)," and that he advises on such matters as Diet, simple Water Treatments, simple Mental Helps, &c. He likes to have full particulars and the medical opinions on each case, and "he then himself prepares a written Health Course or Diet Course, preferably after a Personal Interview (lasting for half an hour or more) with or without an Examination of the Blood, Urine, &c., by a leading Clinical Analytical Expert." The expert, we are informed in another document, is a Mr. Collings, who is there described as "the greatest living Expert." Mr. Miles, however, appears to be willing to give advice by correspondence without the personal interview and without the analytical examination, and we observe that in his tariff of fees "the Full Health Course by Correspondence" costs 2 guineas.

If Mr. Miles is well advised he will stop trying to do work which only a properly trained medical man should do; for despite his disclaimer he is acting in a medical capacity. No one but a medical man has the knowledge necessary to prescribe diets, or exercises, or water treatments upon information acquired from examinations of the blood, urine, or excreta, as no one but a medical man can understand the significance of the information. Mr. Miles's action may not be illegal as the law stands, and unqualified advisers on health have a singular attraction for many minds, but both he and his patients are taking grave risks.

THE PROLIFICITY OF OPPOSITE TWINS.

To the Editor of THE LANCET.

SIR,—The belief mentioned by "H. S. S." in your issue of Oct. 21st has probably arisen from the experience of cattle-breeders. The name "free-martin" was given by Bewick to a cow-calf twin-born with a bull-calf. It has been known from ancient times that she usually proves barren. The subject has been studied by Spiegelberg (1861), Dr. Berry Hart, and Professor Bateson. Sterile free-martins occur only rarely in sheep (Bateson). A clue to the understanding of this subject has recently been given by the paper of Professor Frank R. Lillie, entitled "The Theory of the Free-martin" in *Science*, 1916, N.S. xliii., April 28th, pp. 611-613. He finds that in cattle a twin pregnancy is almost always a result of the fertilisation of an ovum from each ovary; development begins separately in each horn of the uterus; the ova meet and fuse in the small body of the uterus at some time between the 10 and 20 mm. stage. The blood-vessels from each side then anastomose in the connecting part of the chorion. A particularly wide arterial anastomosis develops so that either foetus can be injected from the other. The arterial circulation of each also overlaps the venous territory of the other, so that a constant interchange of blood takes place. If the twins be hetero-sexual the reproductive system of the female is largely suppressed, and certain male organs even develop in the female. This is unquestionably to be interpreted, he says, as a result of hormone action. It is uncertain whether the invariable result of sterilisation of the female at the expense of the male is due to more precocious development of the male hormones or to a certain natural dominance of male over female hormones. Lillie found in a fertile cattle free-martin that the two chorions were entirely unfused; thus he

explains the existence of the fertile free-martin. The sterile free-martin is sterilised at the very beginning of sex-differentiation, and for a long time afterwards male hormones circulate in the blood. Yet, in spite of this, the reproductive system is for the most part female though greatly reduced. Further work is promised by Lillie. If man resembles cattle in this matter then the case mentioned by you forms an exception to the rule. It would be difficult to prove that a sterile "human free-martin" is sterile because of her hetero-sexual twin-birth, for the causes of sterility in women are many. But the question for the statistician is, "Are most human free-martins sterile?"

I am, Sir, yours faithfully,
LEONARD J. KIDD.

P3.—I have given Professor Lillie's description almost verbatim.

THE CONCERTED STUDY OF ENDOCRINOLOGY.

WE have received No. 1, Vol. I., of a publication entitled *The Link between Members of the Association for the Study of the Internal Secretions*. The editor, Dr. Henry K. Harrower, of Los Angeles, provides "medical editors" with some editorial paragraphs for them to employ if they desire, or improve upon in their "own words and style." These paragraphs tell us that the association has been inaugurated with the object of correlating the work of physicians and other students of endocrinology in different parts of the world. We learn that "the charter membership includes nearly 300 physicians in every branch of medical practice, and many of those laboratory workers who are delving into the fascinating mysteries of this field." A scientific bulletin is to be published containing a resume of the work done in this "ever broadening and highly profitable study." The concerted study of the internal secretions may lead to a concerted demand for pharmaceutical preparations of these secretions which may make the study a "highly profitable" one in certain directions, but on broader lines we fail to see much in the programme of promise to scientific medicine. We do not know how the accepted leaders of medical thought in the United States may estimate the movement, as their names do not appear in "the list of applications for charter membership." On the inducement supplied by Vol. I., No. 1 of *The Link*, &c., we cannot recommend our readers to support the movement pecuniarily.

BALACLAVA SURVIVORS' RELIEF FUND.

THAT the hardships of military campaigns are not incompatible with long life is shown by the presence among us of survivors of the charge of the Light Brigade in 1854, the anniversary of which occurred on Wednesday, Oct. 25th. As these heroes must have long passed the age allotted to man by the Psalmist, it is gratifying to know that the needy among them and the widows of those who are dead are being cared for by the Fund which was founded for this purpose in 1897 by the late Mr. T. H. Roberts. But the money in hand is now nearly exhausted. An earnest appeal is being made for immediate financial aid, and donations and subscriptions can be sent to the treasurer, Mr. H. Wyndham Down, the manager of the London and South-Western Bank, Fleet-street, E.C., or to the honorary secretaries, 66, Hatton-garden, E.C. All services in connexion with the administration of the Fund are given free.

THE MEDICAL SERVICE OF THE FRENCH ARMY IN 1849.

THE following figures from the *Annuaire Militaire de la République Française* for 1849 are interesting as affording a comparison with those of the present day (best known to our gallant Ally). The ordonnance of Oct. 19th, 1841, fixed the "cadre constitutif" or the nucleus of units of the "Officiers de Santé" (officers of the Army Medical Service) as follows on a peace footing: A total effective of 1377 officers, of which 127 were Médecins, 1137 chirurgiens, and 113 pharmaciens. The 127 doctors comprised 2 inspecteurs, 14 principaux, 66 ordinaires, and 45 adjoints. The 1137 chirurgiens comprised 2 inspecteurs, 24 principaux, 249 majors, 402 aides-majors, and 460 sous-aides. The 113 pharmaciens comprised 1 inspecteur, 10 principaux, 36 majors, and 66 aide-majors. The surgeons, it will be seen, were nearly ten times as many as the "doctors." The Conseil de Santé des Armées, which then sat at the Ministry of War in the rue Saint-Dominique, No. 82, consisted of five members—that is, two médecin-inspecteurs, two chirurgiens-inspecteurs, and one pharmacien-inspecteur. Their names were Alquié, Vaillant, Bégin, Pasquier, Brault, Baudens (a coöpted member), and Judas, secretary. The Minister for War at the time was Joseph Marcellin Rullière, who was appointed on Dec. 22nd, 1848. In THE LANCET of Feb. 6th, 1909, we published an annotation which is of added interest to-day, on "The Medical Department of the French Army: its Evolution and Campaigns

from 1708 to 1882." In 1849 Magendie, the famous surgeon, curiously enough, had an official job with 11 others in looking after the horses (Commission d'Hygiène Hippique) of the French Army and not the men. The relative value of horses and men at that time may now be food for historical cogitations; but nowadays we have automobiles, and it is the petrol supply which is food for thought.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.

THURSDAY.—Papers: Prof. H. Lamb: On Waves in an Elastic Plate.—Prof. W. H. Young: (a) On Multiple Integrals; (b) On the Order of Magnitude of the Coefficients of a Fourier Series.—Mr. T. C. Sutton: A Determination of the Heat of Vapourisation of Water at 100° C. and 1 Atmosphere Pressure in Terms of the Mean Calorie (communicated by Dr. E. H. Griffiths).—Mr. G. H. Livers: On the Mechanical Relations of the Energy of Magnetisation (communicated by Sir Joseph Larmor).

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Tuesday, Oct. 31st.

PSYCHIATRY (Hon. Secretaries—Bernard Hart, G. F. Barham): at 8.30 P.M.

Presidential Address:

Dr. R. Percy Smith: Mental Disorders in Civilians arising in Connexion with the War.

Wednesday, Nov. 1st.

OPHTHALMOLOGY (Hon. Secretaries—Elmore W. Brewerton, Arthur W. Ormond): at 8.30 P.M.

Card Case:

Mr. G. Winfield Roll: Congenital Pigmentation of the Optic Disc.

Papers:

Lieut.-Colonel and Mrs. R. H. Elliot: The Photography of Macroscopic and Microscopic Eye Specimens.
Dr. Frank Taylor and Mr. Fleming: Bilateral Glioma of the Retina with Multiple Metastases.
Mr. Arnold Lawson: Notes on (1) A Case of Recurrent Glioma of the Retina; (2) Three Cases of Fur Infection of the Conjunctiva.

Thursday, Nov. 2nd.

OBSTETRICS AND GYNÆCOLOGY (Hon. Secretaries—H. Russell Andrews, T. G. Stevens): at 8 P.M.

Special Discussion:

On "The Need for Improvement in the Care of Pregnant Women."

Dr. S. G. Moore (Huddersfield) will introduce the discussion and the different sections will be opened by the following:

Dr. Amand Routh: The Importance of getting all Pregnant Women under Supervision and affording them the Necessary Treatment.

Dr. Comyns Berkeley: The Importance of getting Medical Practitioners and Midwives to Co-operate with the Local Health Authorities.

Lady Barrett: The Importance of linking up all Organisations for Maternity and Child Welfare in Local Health Districts.

The following will take part in the discussion: Professor Briggs, Sir Francis Champneys, Dr. Bardley Holland, Professor Munro Kerr, Dr. Maclean, and Miss Rosalind Paget.

Friday, Nov. 3rd.

LARYNGOLOGY (Hon. Secretaries—Cecil I. Graham, Frank A. Rose): at 4 P.M.

Cases and Specimens:

Dr. Dan McKenzie, Dr. John McKeith, Dr. Wyatt Wingrave, Dr. Irwin Moore, Mr. Stuart Low, Sir St. Clair Thomson, and others.

ANÆSTHETICS (Hon. Secretaries—F. E. Shipway, Ashley S. Daly): at 8.30 P.M.

Communications:

Mr. W. M. Mollison: Successful Case of Heart Massage following Heart Failure under an Anæsthetic.

Dr. M. S. Pembrey and Dr. F. E. Shipway: Observations on the Composition of Air under Masks during Ether Anæsthesia.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY, West London Hospital, Hammersmith-road, W.

FRIDAY.—8 P.M., Clinical Meeting. Cases from the Hammersmith Military Orthopaedic Hospital will be shown by Major Morgan (for Mr. Trethowan), Captain N. Dunn, Captain Elmslie, and Mr. M. Aitken, who will also show some Lantern Slides. Cases will also be shown by Members of the Staff of the Fulham Military Hospital, and others.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East.

THURSDAY.—5 P.M., Bradshaw Lecture:—Dr. H. Mackenzie: Exophthalmic Goitre.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simson: Diseases of Women.

TUESDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Dr. Simson: Diseases of Women.

THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Simson: Gynecological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10.30 A.M., Surgical Out-patients (Mr. E. Gillespie). 2.30 P.M., Medical Out-patients (Dr. T. R. Whipham); Gynecological Out-patients (Dr. Banister). 3 P.M., Medical In-patients (Dr. R. M. Leslie).

TUESDAY.—2.30 P.M., Surgical Operations (Mr. Carson). Clinics:—Medical Out-patients (Dr. A. G. Auld); Surgical Out-patients (Mr. Howell Evans); Nose, Throat, and Ear Out-patients (Mr. C. H. Hayton). Radiography (Dr. Metcalfe). 3.30 P.M., Medical In-patients (Dr. A. J. Whiting).

WEDNESDAY.—Clinics:—2.30 P.M., Throat Operations (Mr. C. H. Hayton). Children Out-patients (Dr. T. R. Whipham); Eye Out-patients (Mr. R. P. Brooks); Skin Out-patients (Dr. E. W. Barber). 5.30 P.M., Eye Operations (Mr. R. P. Brooks).

THURSDAY.—2.30 P.M., Gynecological Operations (Dr. A. E. Gilles). Clinics:—Medical Out-patients (Dr. A. J. Whiting); Surgical Out-patients (Mr. Carson); Radiography (Dr. Metcalfe). 3 P.M., Medical In-patients (Dr. R. M. Leslie).

FRIDAY.—2.30 P.M., Surgical Operations (Mr. Howell Evans). Clinics:—Medical Out-patients (Dr. A. G. Auld); Surgical Out-patients (Mr. E. Gillespie); Eye Out-patients (Mr. R. P. Brooks).

ST JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C.

TUESDAY.—6 P.M., Dr. W. K. Sibley: Eczema and its Treatment.

THURSDAY.—6 P.M., Chesterfield Lecture:—Dr. M. Dockrell: Lichen and Lichenification.

THE THROAT HOSPITAL, Golden-square, W.

MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.

THURSDAY.—5.15 P.M., Clinical Lecture.

CHADWICK PUBLIC LECTURES.

THURSDAY (at the Norwich Museum).—3 P.M., Dr. C. Porter: The Health of the Future Citizen—Lecture I., Motherhood and the Care of the Mother (illustrated with lantern slides).

FRIDAY (at the Lecture Room of the Royal Society of Arts, John-street, Adelphi, W.C.).—5.15 P.M., Professor William Stirling: Fatigue, and its Effects on Industry and Efficiency—Lecture II.: Some Industrial Aspects of Fatigue (illustrated with lantern slides).

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners. Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

Offices: 423, STRAND, LONDON, W.C.

MANAGER'S NOTICES.

ALTERATION OF INLAND SUBSCRIPTION RATES.

INCREASED war expenses and cost of production necessitate an increase in the subscription rates.

The revised Inland Subscription rates are:—

| | |
|---------------------|---------|
| One Year | £1 10 0 |
| Six Months | 0 16 0 |
| Three Months | 0 8 0 |

The revised rates for the Colonies and Abroad (thin paper edition) are:—

| | |
|---------------------|---------|
| One Year | £1 12 6 |
| Six Months | 0 17 6 |
| Three Months | 0 8 9 |

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed) London County and Westminster Bank, Covent Garden

Branch") should be made payable to the Manager Mr. CHARLES GOOD, THE LANCET Offices, 425, Strand London, W.C.

ADVERTISEMENT RATES.

Presidential Address

OR

THE POSSIBLE FUNCTIONS OF THE CEREBRO-SPINAL FLUID.

Delivered before the Neurological Section of the Royal Society of Medicine on Oct. 26th, 1916,

By **W. D. HALLIBURTON, M.D. LOND., F.R.S.,**
PROFESSOR OF PHYSIOLOGY, KING'S COLLEGE, LONDON, ETC.

LADIES AND GENTLEMEN.—So much has within recent years been written about the cerebro-spinal fluid that I must apologise for my want of originality in selecting that subject for this address. But however hackneyed the subject, we are still far from possessing complete knowledge as to the functions and significance of the fluid. From the pathological as well as from the physiological point of view, we at least know that this remarkable fluid is one of the greatest importance, and its careful examination in many diseases has yielded results of inestimable value. During the last few years it is a subject at which I have myself worked, and I have been fortunate in securing as my collaborator such a skilful and accurate experimenter as my colleague Professor W. E. Dixon, F.R.S.

One cannot work at any subject for any length of time without speculating beyond actually observed data. It is the safest rule to keep ideas of this nature to oneself, but there are some occasions when it is permissible to speak rather more freely; this is one of them. I happen to be the unworthy occupant of a presidential chair, and for an hour or less I shall be free from contradiction and criticism, so I propose to inflict upon you during that time some speculations, and have only safeguarded myself in the title of this address by alluding to the functions of the fluid as possible rather than probable. As my colleague Dixon is away on war service, I have had no opportunity of discussing the matter with him, so that if I say anything that is wildly improbable he, at any rate, is free from responsibility.

I shall dwell on the subject from the physiological rather than from the pathological standpoint, but I trust that what I have to say will be found of interest to the pathologist and the clinical observer.

CHARACTERS, COMPOSITION, AND FATE OF THE CEREBRO-SPINAL FLUID.

May I, after this preface, proceed next to another chapter, which is also of a prefatory character, and give you as shortly as I can the present state of our knowledge regarding the characters, composition, and fate of the fluid. The fluid, as you know, is, under normal conditions, as clear as water and of low specific gravity; it contains in solution inorganic salts similar to those in the blood-plasma, a trace of coagulable protein, and a certain amount of a reducing substance which has now been definitely proved to be glucose; it is practically free from formed elements. Under various abnormal conditions the protein matter may be largely increased, or other substances than the usual ones may be added to it, such as cholesterol and choline (or a choline-like substance). It may further have added to it various kinds of cellular structures, the differentiation between which is a valuable aid in diagnosis, and in other cases parasites of different sorts may be found. The fluid is primarily formed by the secreting cells which are so prominently found covering the choroid plexuses in the cerebral ventricles, so that this structure may be appropriately designated, as Mott first suggested, the choroid gland. The fluid is normally present at a certain pressure, and this pressure is not the result of arterial pressure passively transmitted to the fluid. The cerebro-spinal pressure, it is true, may be affected by changes in the arterial and venous pressures, but it is not dependent on them; and it may, and often does, vary quite independently of these. The true cerebro-spinal pressure is the result of the secretory pressure of the choroid epithelium cells. In other words, the cranio-spinal contents cannot any longer be regarded as a fixed quantity without the power of expanding or contracting in volume.

No. 4862.

The rate of flow and the pressure of the fluid can be readily investigated in animals by placing a cannula in the subcerebellar cisterna and connecting it with the necessary apparatus. It is then found that there are three groups of substances which promote the flow and increase the pressure independently of those which affect it secondarily by altering the blood pressure. The first group consists of excess of carbon dioxide (or lack of oxygen) in the blood, as in asphyxia, and drugs which interfere with respiration. The second group is that of the volatile anaesthetics, which may act by interfering with the respiration or by altering the physical conditions of secretion. The third group is specific, and consists of an extract of the choroid gland, or of the brain. The former is the more powerful. The chemical nature of the hormone in this extract is uncertain, but it is probably some product of nervous metabolism, which, arising in the brain, passes to the choroid plexuses, accumulates there, and stimulates the secreting cells to activity; it cannot be discovered in the normal secretion, but in cases of general paralysis and brain softening—conditions in which catabolic processes are excessive—it can be recognised (by physiological tests) in the fluid itself. The choroid plexuses are abundantly provided with nerves, but there is no evidence that these are secretory in nature; indeed, the evidence derived from experiments with atropine and similar alkaloids points in the opposite direction. The hormone, whatever its nature, acts probably not on nerves, but on the secreting cells directly.

There is no doubt that this fluid is being continually formed, and the next question is, What becomes of it? Large quantities of a neutral fluid, such as physiological saline solution, disappear within a few minutes when introduced into the cranio-vertebral cavity, and the course taken by such fluids, and presumably also of the normal cerebro-spinal fluid, can be traced by adding some substance which can be easily recognised by its colour, or by chemical tests, or by its physiological action. Using such methods it has been demonstrated that the exit is by the blood stream, and not by the lymph channels of the nerves, which was formerly thought to be the case by a number of French observers.

If such substances are readily diffusible the speed with which they appear in the blood is very remarkable, especially if they are introduced into the subcerebellar region. An injection, for instance, of adrenaline, nicotine, or atropine produces typical physiological actions within a few seconds, in fact, almost as rapidly as if the injection had been made into the venous circulation direct. On the other hand, substances which are not readily diffusible (such as commercial peptone) do not produce their characteristic effects when they are introduced into the cerebro-spinal fluid, so that one of the older theories that actual valved orifices exist leading into the large veins at the base of the brain must be abandoned.

The diffusion process is most rapid in the subcerebellar district, but is extremely slow in the spinal, especially the lower spinal region.¹ It probably occurs into the venous sinuses by the microscopic arachnoid villi described by Weed. There is also a possibility that in addition to this transference may occur through the thin walls of the blood-vessels within the central nervous system, for, as Mott has pointed out, contact of these vessels with the cerebro-spinal fluid is maintained throughout their extent by the perivascular spaces, which are continuous with the subarachnoid cavity. Diffusion in the opposite direction from blood to cerebro-spinal fluid does not occur except in an almost negligible degree in the case of a few drugs, such as alcohol and urethane.

But in addition to this there is another and minor communication between the fluid and the other parts of the body. Dixon and I found that dyes added to the fluid travel along the course of certain cranial nerves, and this is especially true for the olfactory nerve. This is not the case for the spinal nerves; no dye can be detected in their sheaths outside the spinal canal and no dye is discernible in the lymph of the thoracic duct. I have spoken of this cranial (olfactory) outlet as a minor one, but clinical experience has shown that it is not a negligible one. For this loophole affords an opportunity for the entry of infective

¹ This is tacitly accepted by those who produce spinal anaesthesia by the injection intrathecally of substances of the cocaine group, for they recognise the danger of absorption if the drug reaches the medullary region.

agents, as Flexner has shown in the causation of infective poliomyelitis.

Such, then, is a brief and I fear imperfect summary of the present state of our knowledge, and I propose now to pass to the main object of my address, which is to discuss the meaning and functions of the fluid we are dealing with.

MEANING AND FUNCTIONS OF THE CEREBRO-SPINAL FLUID.

In the first place it can hardly be doubted that the presence of fluid within and around the structures of the central nervous system fulfil certain mechanical functions of support and pressure. That, however, does not explain why ordinary lymph would not do just as well, as it does in the majority of other organs. The relationships, however, of the brain and cord within a closed cavity are peculiar, and it may be that ordinary lymph is here insufficient to maintain a more or less constant pressure. For the pressure of ordinary lymph is wholly dependent on blood pressure; here, in addition, we have an independent pressure—namely, the secretory pressure of the choroidal secreting cells—and it is therefore quite possible that this may come into play in maintaining, equalising, and adjusting those pressure relationships which are most advantageous for the well-being and function of the brain and cord. It is further quite possible that the ameliorative effects not infrequently noticed as a result of withdrawal of the cerebro-spinal fluid by lumbar puncture may be due to the relief of undue pressure. But such considerations offer no explanation of the peculiar composition of the fluid. Its characteristic chemical composition must have a deeper meaning.

It is very common to speak of the cerebro-spinal fluid as the lymph of the brain. Let us now examine this phase more fully, and see if it has any scientific accuracy.

The Cerebro-spinal Fluid regarded as the Lymph of the Brain.

In the first place we must be quite clear as to what lymph is and what it does. It is a fluid which exudes through the thin walls of the blood capillaries. Whether lymph formation depends solely on physical conditions (filtration and osmosis), or whether in addition we have as a factor a secretory activity of the vascular lining membrane is an interesting physiological problem, which need not concern us now. The leakage fluid resembles blood plasma in its composition, except that it is comparatively poor in protein material, the diffusion of which through membranes is so difficult. This lymph, when formed, acts as the intermediary or middleman between the blood and the tissue elements, conveying to the latter on the one hand the oxygen and nutritive substances they need; and on the other hand it is into the lymph primarily that the tissues pour the waste products of their activity, and thus these are started on their journey to the organs of excretion (lungs, kidneys, &c.). The very essence of a lymph is that it should be in free communication, except for an intervening membrane, with the blood stream, and that this membrane should be equally permeable to water and other substances in both directions. The arrangement of the perivascular and perineuronal spaces, filled as they are with cerebro-spinal fluid, certainly resembles that of a lymphatic system, and therefore it is not surprising that the idea has caught on that cerebro-spinal fluid plays in the central nervous system the rôle of lymph. The peripheral nerves have a true lymphatic system analogous to that found in other organs, but anatomists are far from unanimous on the question whether the central nervous system possesses real lymphatic channels apart from the system of intercommunicating spaces occupied by cerebro-spinal fluid. The mere difficulty of discovering true lymph-vessels does not indeed finally negative their existence, but until they are satisfactorily demonstrated we may provisionally assume that they are absent. If, then, cerebro-spinal fluid is the only fluid which actually comes into contact with the tissue elements of the brain and cord, it necessarily follows that it must play the part played by lymph in other districts of the body; it must be, for example, the intermediary medium which is traversed by the oxygen on its way from blood to the tissue elements; and oxygen, we know, is essential for the continuance of nervous life and energy. Furthermore, it must be the vehicle by which other nutriment reaches the cells and fibres of nervous tissue. The next point is, Have we any evidence that the products of nerve catabolism pass into the fluid from the tissue elements as they do into ordinary lymph? If it were only possible to analyse and

compare the composition of the fluid before it enters the perineuronal spaces, and after it leaves them, it would be possible to answer this question authoritatively, but in the absence of such proof one can only argue from probabilities. Seeing that the fluid is the only one available for the purpose, an affirmative answer seems inevitable, and this is supported by the fact that cerebro-spinal fluid is rich, at any rate, in one waste product—namely, carbon dioxide.

The expression "lymph of the brain" is therefore so far justifiable. But we have absolutely no proof that the cerebro-spinal fluid is in part an exudation from the blood, and it is in the origin of the fluid that the analogy between lymph and cerebro-spinal fluid breaks down. Whatever views we may hold as to whether a secretory factor comes into play in the production of ordinary lymph (and, at the best, such a factor can only be an insignificant one), we can have no hesitation in proclaiming that cerebro-spinal fluid is a true secretion arising in a definite glandular structure. Such a fluid must obviously be the best one for maintaining normal life in the nerve cells, and the whole lining membrane of the spaces in which it resides appears to coöperate with the choroid gland in maintaining its constancy of composition, and to militate against the escape into it of substances from the blood stream, such as drugs or poisons which would be foreign to the fluid or harmful to the delicate and sensitive structure which it bathes.

We have seen that the essential feature of a true lymph is the free interchange between it and the blood in both directions. This essential character is lacking in the cerebro-spinal fluid; in all probability the lining membrane of the cerebro-spinal spaces is permeable to substances passing from it into the blood, but it appears to be impermeable (except for oxygen) in the direction from the blood to the fluid. The nutritive materials the fluid contains appear to be formed in the choroid gland, and not to be merely exuded from the blood stream; otherwise one cannot explain why the protein it contains is not similar to that in the blood or in exudations (lymph) formed from the blood.

If, as Weed has suggested, cerebro-spinal fluid is partly formed as ordinary lymph is by exudation from the blood in the perivascular spaces, it is difficult to understand why readily diffusible drugs and poisons do not escape readily into the cerebro-spinal fluid as they do into ordinary lymph. The difficulty is quite intelligible when we regard the choroidal epithelium as a stalwart barrier of cells which keeps back these materials, and only allows its own normal secretion to escape. This useful work would be undermined and frustrated if the general lining were easily permeable to foreign substance.

Camus found that barium chloridé, which is a very active poison to the central nervous system, will kill a rabbit of 2 kgr. weight when 1/10 mgr. is introduced into the sub-arachnoid space, whereas the lethal dose is one thousand times greater when this salt is given subcutaneously. It is well known that anaphylaxis can be produced by smaller doses of proteins administered into the brain than when given elsewhere. The use of salvarsan in locomotor ataxy and similar post-syphilitic affections *via* the cerebro-spinal fluid has been abandoned, as it is fatal not only to the syphilitic organisms, but also to the patient. It is further known that salvarsan and its homologues are of little or no use in tabes and general paralysis when it is given by the ordinary channels, for in these later manifestations of syphilis the baneful spirochæte has got into a harbour of refuge (which we may speak of as extravascular) beyond the reach of the poison. The stalwart epithelial layer lets none escape, and does not realise how much both doctor and patient would rejoice if it could be made to understand that in this instance at least it did not form such an effective barrier.

May I add in way of parenthesis how very desirable it is that chemists and pharmacologists should apply themselves to the solving of this difficulty? The future treatment of tabes and allied conditions should aim at the discovery of some blander arsenic compound which could be introduced straight into the cerebro-spinal fluid and kill the syphilitic organism in its lair without at the same time slaying the host who harbours it.

Significance of the Simple Composition of the Normal Fluid.

Is not the very simplicity of the normal fluid suggestive? I remember when I was a student that normal or physiological saline solution was regarded as a physiological fail,

for surgeons continued to use sponges (usually dirty ones at that time) soaked in water during operations. What a change has now come over the spirit of their dream. They have realised that water, even clean water, is a protoplasmic poison, and that osmosis is a real force and not a negligible phenomenon. I remember at about the same date witnessing, and in a humble measure assisting Dr. Sydney Ringer in his epoch-marking work on the effects of saline mixtures on living structures. The attitude of the profession generally in those days was a tolerant one, just the sort of attitude adopted by a grandfather indulgently watching his descendants playing with their toys. But who has not heard of Ringer's solution to-day? Who can write a paper on almost any physiological or pathological subject without mentioning it or alluding to the part it has played in his investigations?

Ringer's fluid is the ideal physiological salt solution; its saline constituents are present in the same proportion as they occur in the natural body fluids, and in that way the normal osmotic pressure is maintained when living structures are bathed in it. Ringer's original solution resembled frog's blood in its saline composition, but since then several modifications have been introduced. The most important of these is the one we owe to Locke, who has altered the proportion of the various salts (increasing, for example, the amount of sodium chloride from 0.6 to 0.9 per cent.), so that the fluid may be employed with success on the living tissues of the mammal. Locke has also added a small proportion of the sugar glucose, and when in use it is kept saturated with oxygen. It is well known that in such a fluid living structures can be preserved in a living condition for hours or even days and weeks. Locke's most striking results have been obtained with the mammalian heart; this can be kept beating for prolonged periods after its complete isolation from the body if it is perfused with the oxygenated fluid. The salts supply the normal stimulus to the cardiac fibres and maintain their physical integrity; the sugar acts as a source of energy and is consumed as activity continues.

Ringer's fluid, so compounded in the laboratory, is somewhat more than 30 years old. But in reality it is as old as the hills, or rather as man himself. Just as the Venus of Milo existed potentially from past ages in the block of marble from which it was ultimately hewn, so does Ringer's fluid exist in the blood and lymph, although its simple composition is obscured there by admixture with the blood proteins and corpuscles.

Here may I introduce another parenthesis and allude to another physiological puzzle, and that is the significance of the large amount of protein in the blood-plasma and lymph. The meaning and use of the blood corpuscles we understand, or at least we think we do, but the meaning of so large a quantity of protein in the blood fluid and the part it plays in nutrition is still hidden from us. The amount of protein necessary for the repair of the tissues is not great, and the modern doctrine of maintenance and growth is that the tissues help themselves, not from proteins directly, but from the various amino-acids which are the result of protein cleavage. The great protein store may be another instance of the prodigality of Nature in providing a large margin for conditions of weakness and stress. However this may be, the presence of protein is not necessary, or it may even be harmful when it is added to Ringer's or Locke's solutions in experiments with prepared organs.

But to resume the thread of our argument. Thanks to Ringer, some 30 years ago physiologists were provided with a suitable fluid for experimental work, but the choroidal epithelium knew the secret of extracting it from the blood for untold ages before Ringer was born. For what, after all, is cerebro-spinal fluid but Locke's modification of Ringer's fluid?

The view I have been led to take is—the nervous mechanism being so sensitive, so easily influenced by anything unusual—that therefore the neurons must be bathed in an ideal physiological saline solution to maintain their osmotic equilibrium; the trace of protein it contains is probably quite sufficient for nutritive processes, and is no doubt the kind of protein particularly suited to repair the small amount of wear and tear which is the result of nervous action. The sugar, just as in Locke's solution, would serve for a supply of energy. The choroidal epithelium, in its wise choice of a suitable circumambient medium for the neurons, is really exercising a protective function. In order to keep out harmful proteins (toxins and the like), the

comparatively harmless ones are kept back also, almost completely; all share the same process of exclusion. This protective action applies in addition to the majority of soluble drugs; this, as we have seen, may operate so as to be detrimental in diseased conditions. But we can hardly expect discrimination on the part of the epithelial secreting cells. The non-access of metallic and other poisons to the nervous elements is such a *sine quâ non* for their health, that during those periods when such substances are given for the relief of disease, or the slaughtering of parasites, the choroidal cells are unable to change their habits and so they prevent the drugs from getting through.

Such, I believe, then, is the real significance of the simple composition of this remarkable secretion. But before I sit down I must allude, in conclusion, to some other possible additional functions which the fluid may exercise.

Other Possible Functions of the Fluid.

The late Dr. Gaskell approached the question from the embryological and developmental point of view; he held that the neural tube represents an ancestral digestive canal, and those who adopt Gaskell's hypothesis might conceivably argue that the cerebro-spinal fluid is the representative of a primitive digestive juice, and is secreted by an organ which was formerly a digestive gland. However interesting such speculations may be, one can hardly suppose that anyone could seriously urge that the cerebro-spinal fluid retains any such functions to-day.

Dendy is one of many comparative anatomists who have not accepted Gaskell's views, and he has suggested that the important function fulfilled by the choroid plexuses is that of an intracerebral gill, and is concerned in respiration. The structure of the plexuses is certainly gill-like, but it is always unwise to argue from mere anatomical resemblances. Mott, who analysed the gases of cerebro-spinal fluid, found the quantity of carbon dioxide there very high (about 60 per cent.), and there is, therefore, something to be said in favour of the respiration hypothesis. It is quite possible that the choroidal epithelium may allow the escape of, or even actively excrete, this catabolic product, and it is unnecessary to point out how severe a poison any undue accumulation of carbon dioxide is in the central nervous system. Coupled with this fact is another I have previously mentioned—namely, that carbon dioxide is one of the most potent means of promoting a flow of the fluid. Just as urea is the best diuretic and bile the best cholagogue, so carbon dioxide is one of the most powerful cerebral lymphagogues.

One further point and I have done. The ependyma is lined by ciliated epithelium. Some doubt exists, I believe, as to whether the cilia are functionally active. But if we admit they are, the question arises, In which direction do they act? This is a question which is hardly susceptible of actual observation in man or the higher animals, but in the Amnocoetes which Professor Dendy has so largely used in his investigation he has brought forward evidence which shows that the movement is in a forward direction. I know it is not always wise to draw conclusions from such lowly animals, and apply them without reserve to the higher ones. There are certain cases where such deductions are quite impossible; for instance, in some of the humble fishes the central canal of the spinal cord does not terminate blindly at its posterior extremity, but opens out by an orifice into the surrounding tissues. In this case one can only speculate, and the rapidity of absorption of the fluid in the forward regions in comparison with that in the spinal district appears to favour Dendy's surmise, and the cilia, if they are active, would no doubt further the flow of fluid from the cord region to the large veins at the base of the brain, where it so readily leaves the subarachnoid space by entering the venous blood stream.

CONCLUSION.

There are doubtless other problems in connexion with the cerebro-spinal fluid that demand solution, but my task for this evening is over. My main object has been to present the thesis in which I feel there is, at any rate, some truth—namely, to regard the cerebro-spinal fluid as the perfect physiological medium, more perfect doubtless than the artificial fluids we can make in the laboratory, but in its essential features closely resembling those associated with the names of Ringer and Locke.

I think already I have said finally, or in conclusion, more than once, but will you pardon me if, like the proverbial

writer of sermons, I say it a third time, and this is really my concluding message. These are days of specialisation, but however necessary specialisation in medical science may be it has its attendant evils. Particularly regrettable is the divorce between those who pursue their investigations by the bedside and those who work in the laboratory. Neurology specially is a branch of our science in which an attempt should be made to bring about a closer *rapprochement* between the two sets of workers. Speaking personally, I have derived inestimable benefit from meeting with and hearing here the clinical side of the subject. Those responsible for the management of this section of the Royal Society of Medicine have realised this, and in having elected this year a President who is a laboratory person they have shown that they see the value of the *entente* I have alluded to; and I can only trust that my year of office may not be detrimental to those who form the larger contingent in the Neurological Section—namely, those who pursue more specially the study of disease by the bedside.

FURTHER CASES OF KALA-AZAR IN EUROPEANS SUCCESSFULLY TREATED BY INTRAVENOUS INJECTIONS OF TARTAR EMETIC.

By SIR LEONARD ROGERS, C.I.E., M.D. LOND.,
F.R.C.P. LOND., F.R.S.,
LIEUTENANT-COLONEL I.M.S.; PROFESSOR OF PATHOLOGY,
MEDICAL COLLEGE, CALCUTTA.

IN February last I reported, in conjunction with Captain N. H. Hume, I.M.S.,¹ six cases of kala-azar in Europeans treated with tartar emetic intravenously at my suggestion, with recovery in five, and death from complicating phthisis, after the parasites of kala-azar had disappeared from the spleen, in the sixth; and we concluded that the treatment is specific against this very serious disease. We have now been fortunate enough to be able to treat 18 consecutive cases during the last 14 months, with results which fully confirm the very sanguine expectations we formed from the smaller series of cases, while latterly we have been able considerably to shorten the time required for bringing about the cure of the disease by increasing the doses more rapidly than we ventured to do at first. Captain Hume has very generously placed his records at my disposal for the purposes of the

present paper, and I am greatly indebted to him for so thoroughly and successfully testing my method of treating kala-azar with tartar emetic intravenously, which, as already recorded,² I first commenced to use early in 1915, quite independently of the Italian work on the African form of the disease.

In order to enable the salient points readily to be grasped and to shorten the detailed description of the cases, the principal data regarding each have been embodied in the accompanying table, which also includes the first series of cases.

Brief Notes of 12 Further Cases.

The following data are given in the table. The duration of the disease before admission; the number of days in hospital; the duration of fever after the commencement of the intravenous injections of tartar emetic and the number of centigrammes of tartar emetic injected up to the final cessation of fever; and the maximum dose of the 2 per cent. solution given and total number of centigrammes of tartar emetic while in hospital. The table shows the condition before and after the treatment as regards the size of the spleen; the weight of the patient at first and the gain or loss under treatment; the red and white corpuscles, the ratio between them before and after the injections; and the presence or absence of the parasite of kala-azar, which enable the progress obtained to be seen at a glance. The most striking features regarding the individual cases are as follows.

CASE 7.—Female, aged 32, admitted for kala-azar of eight months' duration in a very emaciated state, weighing only 83 lb. 8 oz. (5 st. 13½ lb.), while her white corpuscles numbered only 875 per c.mm. Her arm became much inflamed after an early injection of tartar emetic owing to some of the solution escaping round the vein, so antimony ointment injections were substituted for the intravenous injections. After three and a half months in hospital the spleen was smaller, but the intermittent fever continued, while oedema of the face and feet was present, with albumin in the urine, and the liver was much enlarged, her condition being very unsatisfactory. The intravenous tartar emetic injections were now resumed and the dose gradually pushed up to 10 c.c. of the 2 per cent. solution, which was the strength used in all the present series of cases. After 180 centigrammes had been given in the course of 46 days the temperature finally remained normal, weight was rapidly regained, the parasites disappeared from the spleen, the blood greatly improved, and she recovered her strength and went home to look after her children. She was seen again a few weeks later, when her weight was

found to have increased by 31 lb., or more than one-third of her original weight. This is one of the most remarkable recoveries I have ever seen in a very long experience.

CASE 8.—Male, aged 13. He had suffered from fever for four months and weighed only 48 lb. 10 oz., being very emaciated. Spleen down to the navel and leucocytes only 500 per c.mm. He was treated with antimony inunctions for a month without much effect. Tartar emetic injections were then commenced and gradually pushed up to 7 and 8 c.c., but as vomiting resulted it was reduced to 4 c.c. after the temperature had fallen to normal. After 13 doses containing a total of 124 cgm. had been given in the course of 83 days the fever finally ceased. On discharge from hospital two months later he had gained 24 lb. 2 oz., an increase of almost exactly 50 per cent. on the original weight. The spleen could only just be felt, the blood was normal, the leucocytes having increased more than ten-fold, and the parasites had disappeared from his spleen. Such data speak for themselves.

CASE 9.—Male, aged 38, who had suffered from fever for 18 months. He remained in hospital for 73 days and received a total of 243 cgm. of tartar emetic intravenously.

CASE 14.—Male, aged 48. Admitted in a very weak condition with kala-azar for three months. He had remittent fever, which for two weeks ranged from 102° to 104° and 105°, but fell to normal and a low intermittent type when the doses of tartar emetic had been pushed up to 8 c.c. The treatment was interrupted by an abscess at the elbow, and he now had some fainting fits and on one occasion loss of consciousness for a minute. After he had received 188 cgm. in 35 days the fever finally ceased. He has now been free from fever for eight weeks and is gaining weight steadily and has every prospect of completely recovering from a very grave condition. He was too ill to be weighed until recently.

CASE 15.—Male, aged 45. Admitted for kala-azar of six months' duration. He was exceedingly nervous over the injections, and after receiving 63 cgm. in 16 days, the maximum dose being 5 c.c., he felt unable to go on with the treatment and left hospital. He had improved distinctly, having gained 6 lb. in weight, but still had slight fever, so it is doubtful if the improvement will be maintained in the absence of continued treatment. We have not been able to obtain news of him since he left hospital.

CHART 1.

When the dose reached 10 c.c. he suffered from sickness and lost the little weight he had gained, and he left hospital against advice while still suffering from an occasional rise of the evening temperature to 99.4° F., although his blood had improved and his spleen was smaller. We have not been able to obtain news of his subsequent progress.

CASE 10.—Male, aged 13, who had suffered from fever and spleen for three months. Small doses of tartar emetic were given during the first two months without much improvement. They were then pushed up to 10 c.c., a very large dose for a boy weighing only 63 lb., but except for cough immediately after the injection no toxic symptoms appeared. When he had received a total of 223 cgm. in the course of 123 days his fever finally ceased and he gained weight steadily, putting on 14 lb. 12 oz. before he left hospital, while the parasites had disappeared from his spleen, which was much smaller, and he had become well nourished. He has been recently discharged cured.

CASE 11.—Male, aged 17, who had suffered from fever and spleen for three months. Soon after the tartar emetic treatment was begun he had an attack of pneumonia, which interrupted the treatment for a month. When he had received 66 cgm. in 51 days the fever finally ceased and he began to gain weight, but he left hospital three weeks later very much improved. He reported himself some time later, and had suffered from no more fever, had gained weight considerably, and was quite well.

CASE 12.—Male, aged 47, who had suffered from spleen and fever for three months. In this case no parasites were found on spleen puncture (the only one of the 18 cases not so verified), but he had only 1125 white corpuscles, or a ratio of 1 to 3218, which I have previously shown to be characteristic of kala-azar,³ as was his clinical condition. In this case the amount of tartar emetic was rapidly pushed up by increasing the dose by 2 c.c. every other day until 10 c.c. was reached. The result was most satisfactory, as when a total of 90 cgm. had been given in the course of 23 days the fever finally ceased and he put on weight with great rapidity, actually gaining 24 lb. in 37 days, and he returned to work fat and well three months after his admission. He has been seen recently, nearly two months after his discharge, and has had no return of fever, has gained another 6½ lb. in weight, his blood is normal, and he is quite well.

CASE 13.—Male, aged 20, with a history of fever for one month. He received 75 cgm. of tartar emetic intravenously in 42 days, when his fever finally ceased. The injections were continued for another two months, by which time a total of 362 cgm. had been given. He had now gained 18 lb. in weight, the leucocytes had increased from 1125 to 9250, and his spleen could only just be felt, although it had extended 4 inches below the costal margin on his admission. The parasites had also disappeared from his spleen, and he has recently been discharged cured.

CASE 16.—Female, aged 17, who had suffered from kala-azar for three months. In this case the doses were also rapidly increased by 2 c.c. up to 10 c.c. and given daily at first, but as the 10 c.c. doses caused much sickness it was reduced again to 8 c.c. The rapid fall of the temperature which resulted is illustrated by Chart 1 and it became normal 20 days after the tartar emetic was commenced, when a total of 206 cgm. had been given and she began to put on weight. The red corpuscles have now reached normal, while the leucocytes have risen from 2125 to 10,250, and the spleen, which extended 3½ inches below the ribs on admission, is no longer to be felt. As she has now been quite free from fever for two months there is every prospect of her permanent recovery in a shorter time than in any of the cases described above. She has just been discharged from hospital.

CASE 17.—Male, aged 36, who had suffered from fever and enlarged spleen due to kala-azar for nine months and was in a bad condition on admission. This patient also responded in a remarkable way to rapidly increasing doses every second and third day as shown in Chart 2. After 42 cgm. had been given in 13 days the temperature remained normal, except for a temporary rise due to inflammation of his arm from an escape of a little tartar emetic around a vein. He

CHART 2.

has put on 23½ lb. in four weeks, and his spleen has decreased from 6 inches below the ribs until it is only just felt. This is the most rapid improvement we have yet seen, and, taken with Cases 12 and 16, indicates that by the more frequent injection of rapidly increasing doses to the point of tolerance kala-azar patients are likely to be cured much more quickly than we previously thought to be possible.

CASE 18.—Male, aged 30. Admitted for kala-azar of four months' duration in an emaciated condition. After he had received 86 cgm. of tartar emetic in 36 days the fever ceased. He has recently had an attack of dysentery, which yielded to emetine, and he is beginning to pick up again, but he has

not been long enough under treatment to say more than that he is much improved, but is included to complete the series of cases treated up to date of writing.

Further Progress of the First Series of Cases.

The following is all the information we have been able to obtain of the progress of the first series of cases since they were reported in the former paper. No. 1 has been seen recently, just over a year after his discharge from hospital, and he remains in perfect health and full work. No. 2 was last seen six months after leaving hospital, when he was quite well and his spleen had receded beneath the costal margin, although 2 inches below it on his discharge from hospital. No. 3 died from phthisis as reported. Nos. 4 and 5 have not been heard of recently. No. 6 was still in hospital when we last reported; he was discharged cured four months ago, and has been seen recently in perfect health. Thus no case we have been able to follow up to from four to 12 months after discharge from hospital has relapsed.

Discussion of the Cases.

Technique of the injections.—There is little to add to what was said in the former paper¹ regarding giving the injections. It will be noted that the progress of several cases was retarded owing to an escape of some of the solution around the veins causing severe inflammation and abscess formation usually at the bend of the elbow. The only way to avoid this unfortunate complication is to distend the veins fully by a tight bandage or an elastic band stretched round the upper arm and one end passed in a loop under the other or the ends clipped together, so that it can be rapidly loosened by pulling out the loop or releasing the clip. The vein is then punctured through the skin with a fine sharp needle, taking care not to perforate the posterior wall, and a few drops of blood drawn into the syringe to make sure the needle is in the vein, the constriction round the arm released, and the solution slowly injected. If pain occurs or the smallest swelling appears round the vein stop the injection and suck out as much fluid as possible with the syringe. Collodion on cotton wool may be applied over the puncture. If the veins are difficult to distend by a bandage or rubber tubing the air bag of a blood-pressure instrument may be used for that purpose, the pressure being released before the injection is made. If any of the solution does escape around a vein severe pain occurs at once, which may require morphia for its relief, much induration takes place and sometimes suppuration.

Dosage.—The only alteration we have made in the doses is to increase them more quickly than in the first series of cases. In view of the very rapid improvement which followed this procedure in Cases 12, 16, and 17 we now recommend in adults to begin with 4 c.c. of the 2 per cent. solution of tartar emetic, to add 2 c.c. at the second injection, and, if no toxic symptoms occur, 1 c.c. from that point to 8 or 10 c.c., above which it is not necessary to go. If toxic symptoms arise, other than cough, immediately after the injection, the dose should be reduced until no sickness or nausea occurs, as body weight may be lost as a result of repeated sickness from too large doses. The earlier doses may be given every other day, but when the full dose which is well tolerated is found one injection every three days will suffice.

Toxic symptoms.—Sickness is the most important toxic sign, and its occurrence is an indication for reducing the dose. No serious symptoms have resulted from the large doses given in this series of cases, unless the fainting fits in Case 14 were predisposed to by the drug. Cough just after the injection is common but unimportant. In patients with dropsy or albumin in the urine the dose should be increased cautiously.

Duration of the treatment.—In all except the last five cases and those who left hospital at their own request the injections have been continued for from several weeks to two or three months after the fever had ceased, and only stopped, as a rule, when the body weight had much increased, the spleen become considerably reduced, the blood had approached or reached the normal as regards both the red and the white corpuscles, and the parasites had disappeared from the spleen. This precaution was adopted in view of the great chronicity of sporadic kala-azar, and it has been fully justified by the fact that none of the cases we have been able to follow up for from several months to a year after leaving hospital have relapsed, while most of the

patients are in full work. The question now arises as to how far we have gone on the safe side and whether the duration of the treatment may not be safely reduced. I have previously pointed out² that once a patient, who had become emaciated as a result of kala-azar, loses his fever for a long time and becomes well nourished, the disease does not recur. This experience is amply confirmed by that of over 20 years' experience of Mr. Dodds Price in Assam, who still has scores of coolies doing full work on tea-gardens years after their recovery from advanced kala-azar. An analysis of the present series of cases shows that in nearly all of them the fever finally ceased after from 5 to 12 doses of 5 c.c. and over of the 2 per cent. solution, and that this was first followed by rapid gain in weight and then by diminution in the size of the spleen and great improvement in the condition of the blood. The second spleen puncture, showing the absence of the parasites which had been found before the treatment was begun, was only done after great clinical improvement had taken place, so I am not in a position to say how soon they disappear after the treatment. With the more rapid increase of the dosage adopted latterly Case 16 left hospital apparently cured 65 days after the treatment was commenced, while Case 17 is in an equally satisfactory condition 50 days after the first injection, although he was admitted in an advanced stage of the disease after nine months' fever. In these two cases the injections were continued throughout these periods of time, although the fever ceased after 20 and 13 days respectively, and as the injections of tartar emetic in non-toxic doses appear to have an excellent tonic effect in kala-azar, we advise the adoption of the plan which has proved so eminently successful in these two cases, as can be seen by a glance at Charts 1 and 2, although further experience may show that an even shorter course may be equally efficient.

Effect of the treatment on the fever.—Column 5 of the table gives the number of days after the tartar emetic injections were commenced before the fever finally ceased, while column 6 shows the number of centigrammes of tartar emetic given within that period. In Case 6 the time was greatly prolonged by abscess formation at the elbows, while in Case 10 during the first two months only small doses, but once reaching 5 c.c., were given as he was a poorly developed boy of 13 years. When the dose was increased to from 6 to 10 c.c. the fever finally ceased in five weeks. In Case 8 small and infrequent doses were also given during the first seven weeks owing to his youth, and antimony inunctions were also used. When the doses of tartar emetic were increased to from 5 to 8 c.c. the fever ceased within a month. The same is true of No. 1, in whom the doses were very cautiously increased, but after he had received seven injections of from 5 to 9 c.c., the fever stopped for good. All the evidence then indicates the advisability of rapidly pushing up the doses to from 6 to 10 c.c., or the highest dose short of 10 c.c., which is well tolerated, when the fever may be expected to be controlled after from five to ten doses, given every third day, or within about a month.

Effect on the blood.—The condition of the blood on admission and again at the end of the treatment is shown in columns 11 to 13. A considerable degree of anæmia was present in nearly all the cases on admission, while on discharge the number of red corpuscles was nearly or quite normal in all but three, in one of whom (No. 7) they had increased from 1,740,000 to 3,500,000. Of still more interest and importance is the uniformly great increase of the white, the great reduction in which kala-azar has been shown by the writer³ to be of the utmost diagnostic and prognostic significance. On admission, in no less than 13 of the cases the white corpuscles only numbered from 500 to 2000 per c.mm., while in nearly every case on discharge they had risen to within the normal limits, and in two cases they exceeded 10,000. Such an increase, when not due to a temporary inflammatory condition, is one of the surest signs of the recovery from kala-azar. It does not appear to a marked degree until after the temperature has been normal for some time, so I regard it as a sign of the cessation of the struggle between the parasites and the phagocytes, owing to the former being destroyed by the tartar emetic, allowing the replacement of the lost leucocytes by the normal reparative powers of the system. No case in which the leucocytes have reached the normal has relapsed in our experience, so that a normal leucocyte count is likely to prove a reliable indication for stopping the injections of the

antimony salt. The increase of the ratio of the white corpuscles to the red from the very low figure of less than 1 to 1500, which is usually present in active kala-azar, to within the normal limits of from 1 in 500 to 1 in 1000 is also a very favourable sign.

The effect on the spleen.—The extent to which the spleen reached below the costal margin before and after the treatment is shown in column 9 of the table. Pain is occasionally felt in the spleen after the tartar emetic injections, but little change in the size of the organ appears, as a rule, until the temperature has been normal for some time. When the patients can be kept under observation for another two or three months the spleen becomes much reduced, so that instead of extending to about the navel it may nearly or even completely disappear beneath the costal margin, as in several of the cases in the table. In addition some of the patients have been seen some months after discharge from hospital with their spleens still enlarged, and at the later date it had disappeared beneath the ribs. In some, such as Nos. 16 and 17, it had receded beneath the ribs, so could not be conveniently punctured to ascertain if the parasites had disappeared. The rapid improvement, however, left no doubt in my mind on this point.

Effect on the parasites.—It will be observed that in the great majority of the patients the parasites were found to be absent from the spleen before the patients left hospital, although in all but No. 12 they had been found by spleen puncture before the tartar emetic treatment was commenced. The exceptions are Cases 11 and 15, who left hospital at their own request before a second spleen puncture had been made, and Case 16, whose spleen had risen to beneath the ribs, while the other cases are still under observation in hospital. This evidence completes the proof of the curative action of the drug.

Effect on the body weight.—The rapid gain in body weight by these emaciated subjects as soon as the fever ceases is perhaps the most remarkable and promising feature of the treatment, as shown by the figures in column 10 of the table. Thus Case 8 increased his original weight by almost exactly 50 per cent. in under four months, while Case 7 put on 31 lb. in 77 days, or 36 per cent. of her original weight. No. 12 put on 24 lb. in 37 days, while Case 17 has increased by 23½ lb. in 27 days. Bearing in mind what we have already said regarding the good prognostic significance of a great improvement in the nourishment of kala-azar patients, we regard this result of the tartar emetic treatment as one of the best proofs of its specific action in the disease.

Summary of the Results.

The following figures show briefly the results obtained in the 18 consecutive cases we have treated, which includes every case available in Captain Hume's wards during the 14 months we have used this treatment in the Calcutta European Hospital. Cases are entered as "cured" when the fever has completely ceased for two or more months, together with considerable gain in weight and a restoration of the blood, and especially of the white corpuscles, to the normal and decided diminution in the size of the spleen. This class includes 13 cases. In the two entered as "greatly improved" the temperature has been normal for several weeks, but the general condition has not yet shown that degree of improvement which we recognise as a safe sign of complete recovery. Both are still under treatment with very good prospects. Both the cases entered as "improved" left hospital at their own request before they had received adequate treatment, in one of whom full doses had not even been nearly reached, so that the method had not had a fair trial. One patient died from phthisis after the kala-azar parasite had disappeared from his spleen. The only case in which the treatment might be considered to have failed was No. 15, as the patient said he could not stand the intravenous injections, being a very nervous subject.

Table of Results.

| | | | |
|----------------------|----|-----|-------------------------------|
| Cured | 13 | ... | — |
| Greatly improved ... | 2 | ... | In hospital still. |
| Improved | 2 | ... | Left hospital prematurely. |
| Died | 1 | ... | Died from pulmonary phthisis. |
| Total | 18 | | |

When we remember the most reliable data we have regarding the mortality of kala-azar under careful and prolonged treatment—namely, the cases of my friend Mr. Dodds

Price on Assam Tea Estates, showing a mortality of 96 per cent. at the beginning of the outbreak in the Nowgong district and of 78 per cent. after the epidemic had died down in the district—the above results are so remarkable that it is difficult to find a parallel case in which such a deadly and lingering disease has been brought under complete control by a simple medicinal remedy. (In view of these results I would suggest that the use of tartar emetic appears to be worthy of further study in human trypanosomiasis and sleeping sickness in Africa.) Moreover, it has been shown by Mr. Dodds Price and the writer⁴ that kala-azar has been completely eradicated from the tea estates of the Nowgong district (all of which are now completely freed of the disease, although it had lingered in two of them for 20 years) by the writer's segregation measures, the efficiency of which was first established before even the parasite of the disease was known.⁴ Still further, the progress of the terrible epidemic, which carried off one-third of the inhabitants over some 200 miles of Assam south of the Brahmaputra river, has for long ceased; the segregation and other measures which I recommended in my report on kala-azar of 1897 having proved successful in dealing with the disease in the few villages which became infected in the Golaghat district to the east of Nowgong, as shown by Major T. C. McCombie Young, I.M.S., Sanitary Commissioner of Assam,¹ with good prospect of checking the further spread of the disease through important tea districts. This terrible disease, with its almost unequalled mortality and long-drawn-out sufferings, has thus been rendered amenable to a remarkable degree to both prophylactic and curative measures, largely as a result of the nearly continuous researches of the writer throughout the past 20 years.

DENTAL DISEASE IN NURSING WOMEN:

A NOTE ON THE ASSOCIATION BETWEEN ORAL SEPSIS AND DEFICIENT LACTATION.

By HAROLD WALLER, M.B., B.C. CANTAB.

THE far-reaching effects of sepsis occurring in connexion with the teeth have been so often described that it may be felt that anyone proposing to arouse fresh interest in this well-worn theme must have something entirely original to say before a hearing is deserved. While no claim to originality can be made for the contents of this article, yet it is felt there is still one aspect of the subject which has received less notice than its importance deserves. The particular effect of dental disease referred to is a general lowering of health—a result which in child-bearing women manifests itself by a failure in their power of lactation. It is at once evident that in this particular connexion the disease is capable of producing ill-effects of wider distribution than is usually included in the lists of its commonly accepted disadvantages.

To suggest that dental disease militates against successful breast-feeding is not to suggest that it is responsible for all instances in which the child fails to thrive on the breast milk. It is common for a failure of lactation to be produced in a woman, healthy in all respects, by neglect of the physiological requirements which govern the secretory tissue of the breast. The custom of sucking the infant at frequent intervals is intimately concerned with this type of failure, but it is the method and not the milk which should be blamed. Another source of error is the deduction that the milk is at fault from the restless behaviour of an over-clothed and under-ventilated child. Such mistakes are still responsible for the institution of a great deal of bottle-feeding, and must be corrected before it is possible to form any true opinion of the potential capacity of the lacteal glands. Even so, when the management of the baby and the feeding arrangements are arranged to fulfil the physiological demands of lactation as well as of infant digestion and bodily comfort, there remains a number of cases where the child fails to thrive. Dissatisfaction with the breast-feeds and vomiting are often early symptoms in the child of such a failure. The vomiting

is of an intractable type, variable from day to day, sometimes interrupting the feed, sometimes following shortly after its conclusion; at others interfering with sleep and accompanied by attacks of screaming which may last for hours. The vomiting has a tendency to be frequent, copious and forcible, and the woman rightly concludes that her milk disagrees with the child. The mother of such an infant may present a frail, unhealthy appearance, and it is not uncommon to find that the child is under-sized and that, notwithstanding the correspondence with calculated dates, the birth is thought to have occurred prematurely. In marked cases of the type under discussion there may be observed in the child a persistent blueness of the extremities, quite foreign to one whose diet and digestion are in accord. Where a record of the gain in weight is kept it will be found to proceed at an unsatisfactory rate. It may be that a child several weeks old is no heavier than at birth; or, even when allowance has been made for the reading of the midwife's scales, and they must surely be as elastic as those of fishermen, that there has been a loss of flesh. The association of so many unsatisfactory symptoms can hardly fail to attract attention. But in other instances there is nothing very striking in the woman's appearance to suggest that she is not healthy, though her infant's progress is far from satisfactory.

I have learnt to attach importance in such cases to the presence of oral sepsis in the mother, and it is well to remember that leading questions about the condition of the teeth seldom afford enlightenment. But it will be found that if inquiry is directed to the metastatic effects of oral sepsis positive evidence is given unsuspectingly. Thus, it is common to be told that the woman is rheumatic and is subject to recurrent sore-throat, that she "suffers with her head," or that she constantly wakes in the morning with a bad taste in the mouth. Attacks of neuralgia, stiff neck, swollen face, or "gumboils" are sometimes admitted. Indigestion, vomiting, loss of appetite, and a decline in weight and strength are symptoms often volunteered. Examination of the mouth suggests most strongly the probable etiology of many of these complaints. From a superficial inspection it is often obvious that good general health is incompatible with the conditions found there. Caries of long standing, dead teeth, broken roots regarded as harmless and often covered by plates, the openings of sinuses from which pus can be expressed in quantity, loose teeth with a copious discharge arising from their alveolar insertions—all these are of common occurrence. A chronically infected state of the tonsils must necessarily be added to the list. It is unfortunately common to hear that such patients have for years relied on medicinal remedies for their debility and anemia.

Presenting greater difficulty, but often of equal importance, are the cases where elaborate architectural devices have been built up, and where the mouth contains a number of gold-crowned teeth; for despite their cleanly appearance they do not always, in point of fact, rest on sound foundations. The very form of their construction sometimes serves to imprison disease which has progressed beneath. So also may the costliness of their erection prove a serious hindrance to their alteration or removal. In such cases the knowledge of an expert and impartial dentist may have to be supplemented by skiagrams before the point can be settled.

There would be little object in thus referring to the familiar aspects of a well-known and prevalent disease were it not comparatively easy to show that its ill-effects in nursing women are not confined to the mothers themselves, but are of considerable importance to their children. The real importance of the question lies in the chance which treatment offers of effecting a sufficiently rapid improvement in a woman's health to raise her powers of lactation from a subnormal to a satisfactory level, and so of avoiding the need to rear her child by hand with all the difficulties, dangers, and expense which this process entails. If a change of such unquestioned benefit can be conferred by the removal of dental disease, a tenacious attachment to infected teeth can no longer be regarded simply as a matter of individual preference, to be respected on grounds of personal liberty. The prevalence of the condition must, on the other hand, be recognised as a very disastrous one, claiming attention on national grounds of the first importance in view of the interference it produces with the course of infant welfare. If the sceptic is inclined to think that too much is being made

of a trivial subject, let him notice how infrequent are digestive disturbances and intestinal disorders in breast-fed infants whose mothers are the possessors of perfect teeth.

My own experience has led me to believe that if the removal of dental disease is adequately carried out, even after it has produced symptoms such as have already been mentioned, improvement in the woman's health is sufficiently rapid and substantial to be of signal benefit to her child. But for purposes of evidence a more reliable objective standard is required, and the child's rate of gain in weight provides the most trustworthy guide. Two changes should follow treatment if its effect on a woman's general health is sufficient to influence lactation: (1) the rate of gain in the child's weight should be accelerated, and (2) the length of time over which nursing can be carried out should be prolonged.¹ The demonstration of these two results, either separately or in conjunction with one another, is necessary to substantiate the claim to importance which has been made. They will be reinforced if accompanied by other symptoms in the child of a more satisfactory diet, such, for example, as the cessation of vomiting and willingness to sleep for long intervals between the meals. The mother should also become aware of an increase in the flow of milk. Three cases exemplifying these features will be described.

CASE 1.—The second child of a woman, aged 21, was brought to an infants' consultation at the age of two weeks. The child was above the average in weight and looked healthy. The mother was of frail appearance with a sallow complexion, and in manner anxious and overwrought. She complained of loss of appetite, pains in the head, and inability to sleep. Her first child had been breast-fed for 10 months with success. The second was also being suckled, but cried unduly and vomited the milk from time to time. An unhealthy condition was present in the woman's mouth; above the broken stump of an upper incisor was the opening of a sinus from which pus escaped freely on pressure. The scars of other openings were visible

CHART 1.

Case 1.—Weight curve of child. The continuous line is Budin's curve. The interrupted line gives the record of the child's weight. The arrows denote the extraction of maternal teeth: three in the first case, two in the second. The direction of the interrupted line before the extraction would lead to a weight of 14 lb. at one year, after the extraction to one of 22 lb.

above the position of a tooth which had been broken and over which the gum had united. The removal of the defective teeth was urged, but arrangements for this could not be made for several weeks. Meanwhile the child's gain in weight became unsatisfactory. Reference to Chart 1 will show that by the end of the twelfth week he had lost the initial advantage which he held over the average child at birth. The mother's health was visibly deteriorating, and with lack of sleep and the

¹ In Budin's curve we have a standard which may conveniently be used for the first point in providing an average rate of progress in a child's weight during the first year of life. The normal period of lactation is not easy to fix; as Forsyth has shown, it depends to a large extent on tradition. In one of the cases quoted later it will be noticed that the orthodox period of eight months is exceeded. All this means is that the child was spared for longer the necessity of drinking cow's milk—a fact that can scarcely be stigmatised as "unnatural."

continued fretfulness of her infant she had become depressed and careworn. The prospects of successful breast-feeding had begun to appear altogether unfavourable, and the child to show a definite aversion to the breast milk, when she attended for dental treatment at the London Hospital. Three teeth were extracted when the child was 11 weeks old and two a fortnight later, the mouth healing quickly. Improvement in the health of both mother and child followed at once and the weight curve is seen to rise. Test meals were taken on several different occasions. Before removal of the teeth the child was found to gain 4 oz. in weight in the course of each of three meals. At weekly intervals from the fifteenth week the weights registered at the feeds were 8, 7½, 7½, 8, 6½, 8½ oz., and at the twenty-sixth week 10 oz., by which time the weight was 2½ lb. above the average calculated by Budin's curve. The infant's progress was almost uninterrupted up to the age of a year. Breast-feeding was discontinued during an attack of varicella at the eleventh month, and half-a-pint of cow's milk given instead, with a diet of mixed food.

It is interesting, and perhaps not unduly fanciful, to speculate on the alternatives to this course. To start with, her own teeth were almost the only thing the woman had not thought of blaming for her baby's misdemeanours, so that she would not instinctively have sought the right treatment, in which case it is scarcely conceivable that by means of breast-feeding she would have succeeded in keeping the child in health. Had the baby continued to gain in weight at about the same rate as that recorded during the first three months the curve would have reached at 12 months a height approximately of 14 lb. The actual weight at that age was 22 lb., representing a gain of 8 lb., or more than a third of the total body weight. Much more probably bottle-feeding would have been installed about the fourth month, a plan associated with much risk in this particular household, but inevitable, if the powers of lactation continued to decline. The mother's health, meanwhile, would have been left to fare as best it could.

Failure of lactation in this kind of case is often attributed to the woman's lack of food, and doubtless there are instances in which it is true; but the appearance which gives rise to the diagnosis of starvation is, in reality, more commonly produced by toxæmia, followed by failure to assimilate food and loss of flesh. To increase the food-supply alone is of little or no use. Removal of the cause of ill-health will often show, on the other hand, as in the above instance, that the available food-supply was adequate in the absence of sepsis.

CASE 2.—The first-born child of a woman aged 29, whose health was poor during the first three months of pregnancy,

CHART 2.

Case 2.—Weight curve of child. Lines as before. The arrows indicate the extraction of eight teeth, twelve teeth and four roots, and eight teeth respectively.

escaping from the breasts between the feeds. The child vomited frequently, sometimes when feeding, and sometimes at the end of the meal. On other occasions the milk would be retained for an hour or more and then be forcibly rejected.

Intervals of three and four days elapsed between the action of the bowels. Alterations in the hours of feeding were made until treatment could be arranged in the dental department, but they produced no improvement. The dentist reported that nothing less than radical extraction of every tooth could hope to affect the grave sepsis which was present. The gums were swollen and in some places almost covered the crowns of the teeth, many of which were loose, with pus oozing round them. Caries had long since wrought havoc throughout the mouth and a number of sinuses existed. The patient agreed to the proposal and the dates of the extractions are entered on Chart 2. The child's vomiting ceased almost at once, a daily movement of the bowels was established, and a steady gain in weight followed. Despite her edentulous condition, which made eating difficult, a marked improvement in the mother's health also took place. It is interesting to note that the child did not gain weight until the majority of the teeth had been extracted. Within a few weeks the child's skin improved in colour and the extremities lost their abnormal purple tint. The weight, which had been almost stationary at 5 lb. from the third to the tenth week, rose to 10 lb. between the tenth and eighteenth week.

In this instance it is significant that the milk was not deficient in quantity before the teeth were removed. But the child's vomiting was not caused by taking excessive amounts, for the plan was tried of allowing short feeds of a few minutes only. The milk was still vomited. Moreover, extraction of the teeth could not be expected to lessen the flow, yet vomiting ceased with the diminution in the sepsis. The presence of organisms in the milk was suspected, but cultural examination disproved this. It must be presumed that the milk was rejected on account of some toxic properties, and the details given will serve to emphasise how closely the infant's behaviour resembles that seen in cases of obstruction due to spasmodic closure of the pylorus. The apparent paradox of a child starving itself to death in the presence of a copious supply of its mother's milk is rendered clear if it can be proved that the food contains some virulently toxic substance. Oral sepsis in the mother is not, so far as I am aware, at all frequently suspected as the underlying cause of such misdemeanours in the baby. There is a passage in Still's writing² which seems to apply very accurately to the kind of case under discussion: "Sometimes where the infant was wasting considerably in spite of an ample supply of milk, I have found that as far as ordinary analysis could show the milk was perfectly good; nevertheless the substitution of hand-feeding, partly or entirely, has been followed by immediate improvement. I have no explanation to offer for this occurrence, but it suggests that there are subtler constituents in milk than proteid, fat, and sugar." Some source of toxæmia such as is here suggested would appear to supply an explanation of the symptoms as well as of the improvement which followed a change in the milk-supply.

CASE 3.—A woman, aged 37, sought advice about her seventh child, aged 14 weeks. All the other six were alive. They had been difficult to rear, for breast-feeding had never been successful for more than three months. The majority had required artificial feeding during the second month. One had been hand-reared from birth. Questions elicited the following facts. During the lying-in period the milk was always plentiful after all her confinements, but within a few weeks the child habitually preferred the left breast to the right. The "draught" gradually ceased to be felt on the right side, and suckling was continued from the left side only. At or about the sixth week the left breast would fail to satisfy the child's needs and would be supplemented by bottle-feeds. This measure was always followed by the complete failure of lactation. This, or slight variations of it, is an extremely common sequence of events, though its mention is usually withheld. The left side is preferred by the child because it is habitually carried on the left arm, and is awkwardly held by the right. The right breast ceases to secrete from lack of regular stimulation; the left fails from being overtaxed. In this instance the woman was advised to use both breasts at each feed, making the child take the right before the left. A small quantity of cow's milk was ordered after each feed to ensure the child's satisfaction and so enable a proper interval to elapse between the meals. The plan was adopted with considerable scepticism, but a week later came the report that the "draught" was again felt in the right breast. After a fortnight the supplementary feeding was discontinued and the rate of gain in weight proceeded satisfactorily until the child was five and a half months old. (Chart 3.) At this point lactation showed signs of failing. The rate of gain ceased and a loss of weight occurred. The

² Common Disorders of Children, 1910, p. 21.

breast-feeds gave less satisfaction, and the infant awoke in the night and demanded a meal when previously he had slept peacefully. The mother complaining of headaches, neuralgia, and indigestion, declared the tax of suckling was beyond her powers. After some discussion she now agreed to take the advice given at the first visit

CHART 3.

Case 3.—Weight curve of child. Lines as before. The arrow indicates the extraction of six maternal teeth.

and had six badly diseased teeth extracted. Her health improved conspicuously, and her regrets at having delayed treatment were as sincere as her previous assertion that she was perfectly well. The child continued to thrive, obtained from the breast all the milk he required and was weaned at the age of 14 months. He could walk without support before he was 10 months old, an achievement which had not been reached by any of the other six before the age of 16 months.

In the above example the need for artificial feeding was first threatened as the result of mismanagement when the child was about four months old; it appeared to be again called for at the seventh month on account of the woman's ill-health. The part played by the first factor in the previous failures of lactation was presumably the same. It is not possible to say anything about the effect of oral sepsis on the mother's health; it appeared to be of long standing.

The cases selected as illustrations have been chosen from nearly 200 in which the presence of dental sepsis interfered with the power of nursing an infant. Improvement capable of registration was achieved in 80 per cent.; in the remainder opportunities for recording its effects did not occur—some were lost sight of, and some did not complete the treatment. To the suggestion that herein lies the cause of many instances of the failure of lactation there are drawbacks, not the least being the heavy burden of responsibility which this disease has been asked to carry. Considerable disagreement is apt to occur in discussions which attempt to fix the point at which disease of the teeth is related to disorders in other parts of the body. Yet there seems no way to avoid the conclusion that to its other disadvantages must be added that of playing a very disastrous part in vitiating the course of breast-feeding.

The somewhat elaborate description of the cases will, it is hoped, be excused in view of the difficulty of isolating the essential points of the subject. It follows from what has been said that the earlier treatment is obtained the better. It is difficult to suppose that a condition which can influence a child so profoundly through its parent after birth, can fail to exert effects during intra-uterine life. Research into the association between dental disease and the occurrence of miscarriage and the birth of premature children of weakly physique might well produce important results. It might be hazarded that the appointment of a dental surgeon to the staff of every maternity hospital would greatly increase the utility of these institutions.

The opportunity to present the subject in its present form was intimately dependent on the diagnostic and operative skill of the dentist. Mr. H. C. Highton has devoted his time in the most ungrudging manner to this investigation, and the results quoted bear their own testimony to both his judgment and ability.

Gray's Inn, W.C.

MASSAGE AND MEDICAL ELECTRICITY IN THE AFTER-TREATMENT OF CONVALESCENT SOLDIERS.

ACCOUNT OF THE MECHANO- AND ELECTRO-THERAPEUTICAL DEPARTMENTS AT THE COMMAND DEPÔTS AND CONVALESCENT CAMPS.

By FLORENCE BARRIE LAMBERT, M.B., B.S. DURH.,
D.P.H.,

INSPECTING OFFICER OF MESSAGE AND ELECTRICAL DEPARTMENTS
ATTACHED TO COMMAND DEPÔTS AND CONVALESCENT CAMPS.

WHEN the medical history of the war comes to be written the Director-General's scheme for the establishment of Convalescent Camps, where the work of the general military hospitals can be completed and large numbers of men restored to the fighting service, will be ranked at its full value. That it has not received its full recognition up to the present is due to the quiet and gradual way in which the whole scheme of after-treatment has been set on foot. The public might be led to suppose from the articles which have lately appeared in the lay press that we in this country have very little in the shape of an organised scheme for the after-treatment of our convalescent soldiers, and even in quarters which might be expected to have the fullest information there seems to be a disposition to magnify French achievements rather at the expense of our own. Thus in the report of the Special Committee of the Balneological Section of the Royal Society of Medicine appointed to consider the treatment of disabled soldiers by physical remedies there appears the following statement:—

Up to the present time physical remedies have not been used with the same thoroughness and precision as in France. In England heat, moist and dry, massage, and electricity are, of course, used throughout the country, and in a few cases baths and mechanical movements are being added. What is wanted is a combination and association of these powerful agencies under skilled direction. We think that a clear case has been made for the introduction of physical treatment upon an adequate scale into this country for the benefit of disabled and discharged soldiers. It is true that the *eau courante* bath of the French or the analogous whirlpool bath used in England has been adopted in some British hospitals. This, however, is but a single item in the treatment to which we refer, although its adoption may be regarded as a tacit admission of the good results that are being obtained by our French and Belgian allies.

Such a statement is misleading in that it passes over as practically non-existent the splendid work of the Command Depôts and Convalescent Camps, chiefly because the *eau courante* bath has not been installed broadcast. After all, this mode of application is still in its infancy, and while one is always anxious to test any new and improved methods of treatment, it will be very interesting, to say the least, to have the views of the medical profession two years hence on the efficacy of the *eau courante*, now very much on its trial, when compared with ionisation, radiant heat, diathermy, and massage in the treatment of ankylosis and similar conditions. It is noteworthy, however, in this connexion, that in recent statistics published by the War Office of men returned fit to their units from the Command Depôts, Randalstown heads the list. Owing to the very imperfect water-supply it has been found impracticable to install any form of hydrotherapy at Randalstown, and, therefore, only these latter time-honoured methods of treatment have been available.

The physical and electrical treatment of convalescent soldiers is by no means so lacking in coördination and skilled direction as certain criticisms might lead one to infer. It is necessary to be actually at work in the camps in order to appreciate how thoroughgoing a system it is which is being set up; but even a casual visitor would find it a revelation were he to go to any of the camps (say the one at Epsom, which is the most accessible from London) and watch the work carried on any morning or afternoon inside the massage and electrical department.

The Convalescent Hospital Camps.

Before the first six months of the war were over it became apparent to the Director-General that a great number of men were being discharged from military and Red Cross hospitals who, on account of stiff joints or injured nerves, were unable to return to duty, although they no longer required hospital treatment. These men were at first given extended leave at home, and were dealt with in out-patient departments

attached to the civil hospitals and in various special centres of treatment. Mr. and Mrs. Almeric Paget's massage and electrical centre at Portland-place, which I organised with the help of the Hon. Essex French, can, I think, claim to be the parent of the mechano-therapeutic departments subsequently attached to the Convalescent Camps, for it was after inspecting this centre that the Director-General asked that similar departments should be organised in connexion with the camps. The circumstances under which many of the men were living, however, militated against their recovery, and then it was that the Director-General instituted, at Eastbourne, the first of the great medical Convalescent Hospitals or Camps.

The idea governing this scheme was that men discharged from hospitals and convalescent homes should receive a final six weeks' treatment before being returned to their unit. Unfortunately, the first batches of patients were largely unsuitable, many of the men suffering from injuries so severe as to incapacitate them from all further service, while in other cases a year or more would have been required to effect a cure. The result was that a great many patients had to be returned to the hospitals. Eventually, however, the work at the camp settled down to the normal level, and the cases dealt with were of the kind for which the scheme was intended—namely, cases of stiff joints, slight nerve injuries, trench feet, fibrositis, &c.

A large mechano-therapeutic department was established in the camp to which I was appointed medical officer in charge. The electrical installation comprised 14 wall switchboards, worked from 50 accumulators, each of two volts, and furnishing galvanic, faradic, and combined currents as required. There was also a plentiful supply of local radiant heat, and Schnee four-cell baths, and vibrators worked from the main. As a great number of assistants were necessary whom it would be difficult to supervise in detail, it was thought well to keep the apparatus as simple as possible. Subsequent experience of many departments attached to Convalescent Hospitals and Command Dépôts has strengthened my opinion that, where a large staff is necessary, the simpler the apparatus the better the result.

At the outset we were faced with the problem that although a fair number of masseuses and remedial gymnasts were available, the supply of electricians was very limited, and there were no reserves to draw upon. We got over the difficulty as well as possible by splitting up the staff of 25 masseuses into squads of 5, placing in charge of each squad a masseuse who was known to be a skilled electrician, and making her responsible for the work and tuition of those under her. The plan proved very satisfactory, and was afterwards adopted in the camps at Epsom and Dartford, with the result that when, some six months later, the Command Dépôts were started we had a nucleus of experienced and practical electricians to draw upon. At present most masseuses, before starting work, take a course in electricity, and thus come with the advantage of some practical experience in the working of the delicate apparatus entrusted to them.

The standard for masseuses employed in military work is that they shall have had not less than six months' training, and shall either hold the certificate of the Incorporated Society of Trained Masseuses or satisfy a board of examiners set up by the War Office. The great bulk of the military workers—90 per cent. is probably an under-estimate—hold the certificate of the society. We have the safeguard, therefore, that our workers are trained women. The training may not in all cases have been as complete as we could wish, but when comparisons are made with the conditions on the other side of the Channel, it is well to remember that the length of training in this country is in very favourable contrast to that which is considered sufficient in France.

The camp at Eastbourne is a large one, with 3000 patients, and the visits to the electrical department each day vary between 600 and 800. By dovetailing the radiant heat and electrical applications and the massage, it is found possible for each masseuse to treat from 20 to 22 cases a day, each case receiving from 20 to 30 minutes' treatment, and in some cases longer. In July of last year I was appointed medical officer to similar Convalescent Camps which were established at Dartford and Epsom. The Dartford camp is comparatively small, with only 1200 patients, and never more than from 150 to 200 daily treatments in the department; at Epsom the camp is very large, with 4000 patients

and between 500 and 700 men treated daily. Both camps have been fitted with apparatus similar to that installed at Eastbourne. There are now five Convalescent Camps in all, the two latest being in the North of England, and although statistics can only convey a skeleton-like notion of such work as this, some figures may be of interest:—

| | A. | B. | C. | D. | E. |
|----------------|-------|--------|-------|-----|----|
| Eastbourne ... | 2,880 | 26,760 | 2,696 | 772 | 29 |
| Epsom ... | 4,000 | 29,642 | 3,050 | 730 | 25 |
| Dartford ... | 1,200 | 9,502 | 957 | 207 | 11 |
| Blackpool ... | 2,113 | 4,319 | 2,030 | 525 | 20 |
| Alnwick ... | 2,080 | 7,536 | 1,878 | 512 | 20 |

A. Total capacity of camp. B. Total number of men passed through the dépôt. C. Number of men in camp on Sept. 20th. D. Number of men undergoing massage, electricity, and special exercise treatment on Sept. 20th. E. Number of masseuses.

The Command Dépôts.

Even the Convalescent Camps proved not to be the last word in this system of after-treatment. It was found that after six weeks or so in such a camp there was a residue of men who, although quite capable of being cured, would require a much longer period—anything from four to six months. To provide for these cases the Command Dépôts came into being. These are camps in which convalescent soldiers belonging to particular commands are grouped, and their administration resembles rather that of a military barracks than that of a hospital. The men are in khaki, and are subject to more fatigues and drills. The military commandant is at the head of the camp, the medical officer being the senior medical officer.

To some extent the Command Dépôts have become places for separating out the unfit, for the cases treated are necessarily of a very chronic type. There are periodical inspections by medical boards, when men incapable of further military service are discharged and pensioned. All cases in which there appears to be no improvement and in which surgical interference may be desirable are periodically paraded and examined by the Inspector of Orthopædics or his representative.

Some idea of the life of a patient in a Command Dépôt may be given in order to illustrate what a finely coordinated scheme it is which has been put in practice. Usually the patient arrives at the dépôt in the evening and goes straight to the Welcome Hut, run by ladies of the district, where he gets a good meal. He then goes to his company, and is told to report to the senior medical officer next morning. He is duly seen by his company's medical officer, and all details of his history and condition are set out on a card, after which he is grouped for treatment. This grouping and the scheme of treatment generally varies to some extent in each dépôt according to the ideas of the senior medical officer in charge. A representative instance may be taken in the six groups into which the men are divided at Seaford:—

Group I.—Men practically fit, but requiring a final hardening process. Subjected to drill, route-marching, fatigues, and gardening.

Group II.—Men receive physical drill under Aldershot drill-sergeants and staff, and have short route-marching, light fatigues, and general sports.

Group III.—Men have walks, physical training, light fatigues, and lectures on personal hygiene and other topics of interest.

Group IV.—Mostly medical cases, such as nephritis and heart affection, and convalescence after abdominal operations, pleurisy, &c. Subjected to walks, light physical training, gardening, and lectures.

Group V.—This group comprises the larger proportion of the massage cases, such as stiff joints, trench feet, nerve injuries, and sciatica.

Group VI.—Cases of shell-shock or cases so shattered as to be unfit for any form of exercise other than gardening, and walks, and certain special movements to improve co-ordination.

The men are kept under strict observation and continual medical inspection, and are passed up or down the scale according to their physical ability. The senior medical officer personally sees every man before he is transferred to a different group after the preliminary selection by the medical officer.

When a patient is sent to the massage department a fresh card is made out on which all particulars are entered and the required treatment also set down. Here he receives the exercises and movements and electrical and heat applications which are suitable to his case. If it is thought necessary, he is also given remedial gymnastics, or, as it

is sometimes called, re-education of movement. This department is in the hands of remedial gymnasts who have received two years' training. I give below a table of the remedial gymnastics ordered for the convalescents at the Heaton Park Dépôt, where Major Tait McKenzie, who is professor of physical education at Philadelphia University, sets great store upon physical exercises.

No. 2. Remedial Exercises: Single Shoulder (Tait McKenzie).

a. Movement with resistance.—(1) Arm raise sideward with resistance; (2) arm lower sideward with resistance; (3) arm raise forward with resistance; (4) arm raise backward with resistance; (5) arm circumduct with resistance.

b. Pulley weight.—(1) Position: Side to, arm sideward raised. Movement: Arm forward across chest, elbow straight. (2) Position: Side to, arm sideward raised. Movement: Arm upward raise, elbow straight. (3) Position: Side to, arm sideward raised. Movement: Arm downward and forward, arm downward and backward alternating. (4) Position: Side from, arm across chest. Movement: Arm sideward, elbow straight. (5) Position: Side from, arm downward and behind. Movement: Arm side upward raise (floor attachment).

c. Shoulder machine.—Stretching contractures up to point of pain (if pain persists discontinue and report).

The dépôts bear a general resemblance to each other, but, naturally, both the equipment and the methods vary according to the individual views of the senior medical officer. At Ripon, for example, the Bergonié current—i.e., a rhythmically interrupted and reversed faradic current—and leucodescent lamps are used in preference to radiant heat or ordinary faradism; at Blackpool high frequency is largely employed; and at Tipperary a scheme for teaching men trades is being developed—a kind of educative convalescence.

The average length of time a man remains in each dépôt is from 2½ to 3 months. After being hardened in Group I, he is then, if fit, transferred to Army category A, B, or C. There are various subsections in each category, but, generally speaking, the men in A undergo full military training and are returned to their units in 10 or 14 days ready for transport overseas with the next draft. In category B the men, although physically sound, are withheld from general service by reason of some disability, such as old fractures, "football knees," amputated fingers, and the like, and such men are passed for garrison duty. In category C the men are considered only fit for duty at home and for sedentary occupations. The extent of the work carried out in the Command Dépôts may again be put to the test of figures:—

| | A. | B. | C. | D. | E. |

Total Number of Men Undergoing the Special Treatment in the Convalescent Camps and Command Dépôts.

46,440 ... 127,132 ... 33,869 ... 8,262 ... 304

A. Total capacity of camps. B. Total number of men passed through the dépôts. C. Number of men in camp on Sept. 20th. D. Number of men undergoing massage, electricity, and special exercise treatment on Sept. 20th. E. Number of masseuses.

French and British Methods of Mechano-therapy.

In conclusion, a few words may be said with regard to the salient points of difference between French methods and our own as they suggested themselves to me during a recent visit to Paris.

(a) The first point to note is that in France the men are more often treated as out-patients, whereas our men are treated in camp, and are, therefore, subject to a more continuous routine both of treatment and discipline.

(b) In an examination the French lay more stress than we do on electro-diagnosis; each man is also measured more fully than is usual in our camps.

(c) In actual massage the French work is not to be compared with our own. As I have already pointed out, no one in this country is employed in military work with less than six months' training, while in many cases the training has been prolonged for a year or two years. In France, on the other hand, there is no trained body of masseurs or masseuses comparable to the Incorporated Society of Masseuses. In

July of last year the French military authorities were compelled to start a training school for massage at the Grand Palais, in Paris, where there is also a large *hôpital complémentaire* for cases that require physical remedies, but the training is inadequate—at least, according to our standards. The tuition lasts for one and a half hours every day for a month, half of this daily lesson being devoted to anatomy and the other half to massage.

(d) As regards medical gymnastics and the so-called re-educative movements, the French rely mostly on the Zander apparatus, which has never been popular in England. Its vogue in France is not due to any conviction as to its soundness, but simply to the fact that there is no trained body of medical gymnasts to do the work. Our corresponding treatment is mostly in the hands of medical gymnasts who have either taken the extra six months' course in medical gymnastics in addition to the massage course or hold the two years' certificate of one of the physical training colleges. There are few who will not agree that passive mechanical exercises can never give the same results as good manual work.

On the whole, although British mechanotherapy has still many things to learn, the reproach of lagging behind our Continental Allies cannot justly be urged either with regard to our physical methods in particular or our system of after-treatment in general.

ULTRA-VIOLET RADIATION FROM THE TUNGSTEN ARC.¹

By W. J. TURRELL, M.A., M.D. OXON.,

ELECTRO-THERAPEUTIC PHYSICIAN TO RADCLIFFE INFIRMARY, OXFORD.

At a meeting of the Section of Electro-Therapeutics of the Royal Society of Medicine in January last Dr. E. P. Cumberbatch and Dr. A. Macgregor read notes on several cases treated by the so-called Simpson light. Most of these cases were either cured or showed marked improvement. Dr. J. H. Sequiera at the same meeting clearly demonstrated the non-penetrating character of this radiation and its identity with the already known method of treatment by ultra-violet radiation. Dr. Sidney Russ also showed that, tested by the spectroscope, the radiation from the Simpson or wolframite electrodes was practically identical with that from metallic tungsten. It was, I think, perfectly obvious from the papers and discussion that evening, if tungsten was readily obtainable and burnt satisfactorily in an arc consuming a small amount of current, that the metallic electrodes would prove a far more satisfactory source of ultra-violet radiation than electrodes made from the impure ore. I endeavoured without success for some months to obtain a supply of tungsten from the makers of electrical apparatus and from other sources. I was told on every hand that tungsten had always been very difficult to obtain, and that since the war it had become practically unobtainable. Discouraged by this failure, I had at last to have recourse to the Simpson electrodes both in my private and in my hospital work. These electrodes I found burnt badly, always with much spluttering, and frequently requiring grinding before they would burn at all. They were, moreover, very expensive, as they cost £2 the pair and were very quickly consumed. Subsequently, as a great favour, I obtained two short rods of tungsten each about 1½ inches in length. These I found burnt very steadily, produced what I may call the erythema dose in a comparatively short time, and were very slowly consumed. Patients whom I had already treated by radiation from the Simpson electrodes, and whom I subsequently treated by the tungsten radiation, all expressed themselves as having been more benefited by the radiation from the metal. This increased benefit was, I think, due to the greater intensity of the radiation from the metal, and the greater accuracy with which the dose could be administered owing to the more steady flame.

A short time ago I had the good fortune to be placed in communication with the British Thomson Houston Company of Rugby, and they very courteously supplied me

¹ A paper read before the Section of Electro-Therapeutics of the Royal Society of Medicine on Oct. 20th, 1916.

with a number of tungsten rods of different sizes. They assure me that there will not be the slightest difficulty in supplying any quantity of these rods that is likely to be required for medical purposes. The price will be only a few shillings for a pair of electrodes. This will compare favourably with that charged for the Simpson electrodes, especially when it is borne in mind that the metallic electrodes last about ten times as long. The Simpson lamp, costing £25 to £30, sold for the wolframite electrodes, struck me from the first as a needlessly costly and bulky piece of apparatus, for there seemed to be no reason why a simple arc lamp with sufficient insulation to take a current of 15 ampères should not answer every purpose required. After some search I bought a No. 9 empire arc lamp for £3 3s. from Messrs. Butcher and Sons, of Camera House, Farringdon-avenue. This proved such a satisfactory lamp for the purpose that I have bought a similar one for the hospital.

At my house I work my lamp off my X ray resistance, clamping the lamp to the tube stand so that it can be readily raised or lowered. If one has not a suitable resistance this piece of apparatus will cost an additional £4 9s. 6d. The price of this lamp has recently been raised 12s. In my hospital work I have been using an ampèrage of 9 to 11; in my private practice I use about 7 ampères. With the present pressure in hospital work it is necessary to make the exposures as short as possible. Moreover, the heavier currents seem indicated by the researches of Cernovodaeno and Henri, who found that a 24-hour culture of colon bacilli was completely sterilised in one second at a distance of 20 cm. with a current of 4·7 ampères at a voltage 140, whilst with 2·3 ampères at 23 volts an exposure of 300 seconds was necessary to sterilise the culture.

The therapeutic value of ultra-violet radiation appears to be due to its destructive action on micro-organisms and to the active hyperæmia which it induces in the superficial tissues. The latter is probably of the greater clinical value, and within certain limits the intensity of the erythema produced in the skin in a given time may be taken as a measure of the clinical efficiency of the radiation from the different arcs. In conjunction with Mr. C. A. Schunk, of Ewelme, near Oxford, I recently made a few simple experiments on this erythema dose. Different areas of the skin of the forearm were in turn exposed to the action of the following electrodes: Simpson electrodes, metallic tungsten, cored carbons containing uranium oxide, Ur. 308, with others containing the powders of tungsten, wolframite, and iron. The exposure was for five minutes at a distance of 12 inches with a current of 5 ampères. The most intense erythema was obtained from the metallic tungsten; the next in intensity was that from the Simpson electrodes. None of the other electrodes produced any erythema in the five-minute exposure.

At Oxford we use the two methods of treatment by the ultra-violet radiation—that is, by the use of a reflector and by the use of a quartz condensing lens. In using the reflector method the structure of the mirror is of considerable importance when dealing with wave-lengths of the ultra-violet region. Silicon, which reflects 75 per cent. of the ultra-violet rays, is the most efficient. Nickel reflects 40 per cent., copper 35 per cent., and silver only 6 per cent.² In this method of treatment the patient is placed about 12 inches from the arc and the reflector confines the radiation as nearly as possible to the treated area. We usually adopt the focussing method; in this the quartz lens is held in a wooden shield and the rays are focussed on the area to be treated. In the treatment of granulating wounds special attention is directed to the stimulation of the granulating edges. The shield holding the lens should be sufficiently large to protect untreated areas from the action of the light.

In administering tungsten radiation special attention should be paid to the protection of the eyes of the patient and operator. Hooded frames containing No. 2 Crookes' glass should be worn. I am showing a pair of such glasses made by the Oxford Optical Company. I think also, if much treatment is done, a mask or veil should be worn by the operator, or it might possibly be more convenient to fit a shield to the lamp to cut off the extraneous rays.

In addition to the large lamp, which, of course, requires heavy wiring, I am showing a small lamp, which only takes

4½ ampères and can therefore be used from the ordinary lighting circuit. Smaller electrodes are used in this lamp; a finer point of light is obtained which is very convenient for the focussing method. A suitable lamp for this purpose can be purchased for about £2, including the necessary resistance. In the selection of cases for ultra-violet radiation it is important to bear in mind the superficial action of this treatment. Indolent and extensive sloughing wounds have been much benefited, but the results obtained have been much better where one or two preliminary treatments by zinc or chlorine ionisation have been administered. In barbers' itch and pustular eczemas the treatment has been very useful, but here again preliminary zinc ionisation conduces to a speedy cure. Certain cases of ulcerating lupus have improved. The nodular type with little or no ulceration has not been benefited unless previously fulgurated. Cases of eczema of the face and arms have done very well, some of them very old-standing cases. Eczema of the hands, where, of course, the skin is thicker, has not done so well. A case of lupus erythematosus shows at any rate temporary improvement. The treatment of rodent ulcer by ultra-violet light, unless the case has been freely fulgurated, has not been successful in my hands; the treatment by radiotherapy of these cases is far more satisfactory. The erythema set up by the radiation is sometimes useful in allaying the pain of neuritis.

It has been suggested that ultra-violet radiation might be more conveniently and more efficiently administered by means of a tungsten filament in a quartz globe. The B.T.H. Company constructed for me a 1000-watt 100-volt tungsten filament lamp of 2000 c.p. Mr. Schunk, on examining this lamp with the spectroscopic, found that its spectrum stopped at 3700, and was therefore useless for ultra-violet radiation. This result was, of course, to be expected, for when a solid body is heated to incandescence, the wave-lengths stop at about 3500, and a continuous spectrum is obtained. This spectrum is the same with different solids, and does not extend far into the ultra-violet region. On the other hand, in using metals in an electric arc, the metal is heated to volatilisation, and the specific radiation and spectrum of the metal used is obtained. With a mercury vapour arc as in the Kronmeyer lamp there are a few very intense lines in the ultra-violet region, but with the tungsten arc there is almost a continuous spectrum in that region.

The therapeutic value of ultra-violet radiation has been established for some years. The electric arc is the simplest and most convenient means for its production. The amount of ultra-violet radiation obtainable from any metallic electrode appears to be directly proportionate to the melting-point of the metal. Tungsten has the highest melting-point of any metal obtainable, therefore tungsten arc electrodes would appear to be the most efficient source of ultra-violet radiation at present available. I should like, in conclusion, to express my indebtedness to Mr. Schunk for much valuable information in regard to the physical properties of ultra-violet radiation. Since writing this paper I have received the following letter from Mr. Schunk, from which it will be seen that the conclusions he arrives at are in accordance with those stated above. He says:

"The following are the tentative results I have arrived at, and of which, if of interest, please avail yourself on Friday:—1. The tungsten arc is the most intense source of ultra-violet light so far experimented with, the lines being so numerous and close together that they constitute almost a continuous spectrum. 2. The Simpson electrodes give the tungsten spectrum with the addition of the iron lines, but on the photographic plate with the same exposure and ampèrage are not so intense, no doubt this is due to the unsteadiness of the arc compared to that from the tungsten rods. 3. Half-inch cored carbon electrodes filled with wolfram (75 per cent. tungsten and 25 per cent. iron) burn very steadily and give an identical spectrum as the Simpson electrodes, but the intensity as recorded on the photographic plate is not quite so intense. 4. The iron arc is very rich in lines in the ultra-violet region, but compared to tungsten fails at about wave-length 2500, whereas tungsten extends to wave-length 2160 without much diminution. 5. From the spectroscopic point of view, giving the Simpson electrodes and the carbons cored with wolfram an increased exposure compared with the tungsten arc, one would expect to get the same result from the ultra-violet light treatment point of view.

Hyperæmia experiments.—Using the tungsten arc and a quartz cylindrical condenser, forming an image 18 inches from the condenser, about ½ inch wide, in the form of a strip on

² The Reflecting Power of Metals in the Ultra-violet Region of the Spectrum, *Astraphysical Journal*, p. 205, vol. xlii., 1915.

the skin: 1. A piece of ordinary thin photographic glass. No reaction in $2\frac{1}{2}$ minutes. Spectroscopic examination 3000 wavelength recorded. 2. A piece of microscopic cover-glass. An appreciable reaction in $2\frac{1}{2}$ minutes. Spectroscopic examination 2700 recorded. These tentative experiments tend to show that radiations of 3000 Angström units and upwards have no effect as judged by the hyperæmic effect, whereas from 2700 to 3000 wave-length there is an effect."

Oxford.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF FRACTURED SCAPHOID AND OS MAGNUM IN A BOY 10 YEARS OLD.

BY CLAUDE GOULDESBOUGH, M.B., B.CH. OXON.,
M.R.C.S., L.R.C.P. LOND.,

ASSISTANT SUPERINTENDENT, X RAY DEPARTMENT, AND MILITARY RADIOGRAPHER, ST. THOMAS'S HOSPITAL, S.E.; AND LATE CONSULTING RADIOGRAPHER, BRITISH EXPEDITIONARY FORCE.

THE excuse offered for publishing this case lies in its rarity. Fracture of one or more of the carpal bones in an adult is comparatively common, especially the scaphoid, although injury to the unciform and pisiform is very rarely seen. It is a different matter, however, in the case of children; in their case the part which suffers in most wrist injuries is the epiphysis of the lower end of the radius, which is displaced forwards or backwards, taking with it a chip of bone of the adjacent diaphysis. Fracture of carpal bones in children must be very rare—the records of

St. Thomas's Hospital fail to show, as far as can be seen, any case of this type of injury. It is therefore very interesting to come across a juvenile wrist showing fracture of two of the small bones, but there is also another interest attached to this case to which reference will be made later, and that is the subject of repair. The history of the case is as follows:—

The patient, a boy of 10—a case under the care of Dr. Edward Hedley—was sent to me because of an accident a fortnight old which occurred when he was endeavouring to land a small rowing-boat. His hand was crushed apparently between the prow of the boat and the stone wall of the harbour. The injury was pretty severe, and apart from some swelling at the time he sustained loss of function in his hand in a way that suggested some damage to the median nerve. When I saw him a fortnight after the accident he was still unable to "make a fist," but two days later,

according to Mr. C. A. R. Nitch, who was called in to give him surgical treatment, this power had returned. I noticed at the time that the patient had pain on pressure directly over the scaphoid, but dismissed the idea of fracture of that bone from my mind as being hardly possible. The appearance of the fracture suggests, I think, a direct injury, and the history rather supports the view that the damage was caused by the sharp edge of metal on the prow of the boat striking the hand in an oblique direction corresponding roughly with the line of fracture of the two bones.

It will be interesting to follow the future of this case from the point of view of union. It is a well-known fact that in adults very rarely, if ever, does a fractured carpal bone unite, at any rate by bony union. From X ray appearances it is impossible to distinguish an old from a recent injury—both presenting exactly the same appearance. In the case of this patient I understand that at present no operative measures are intended, the surgical treatment being limited to extreme hyper-extension at the wrist-joint with immobilisation in this position in order to give the best possible chance for union to take place. Skiagrams taken at intervals—considerable intervals—ought therefore to shed some light as to whether the prognosis in cases like this is as bad as it is in cases of adults.

Welbeck-street, W.

PREGNANCY COMPLICATED BY INCREASED CEREBRO-SPINAL PRESSURE;

SURVIVAL OF MOTHER AND CHILD.

BY NORMAN GRAY, M.A., M.B., B.C. CANTAB.

THE following case appears to me to be of some interest to general practitioners, and as, to my knowledge, no similar case has been recorded during recent years I propose to give a short account of it and of the treatment adopted.

On June 9th, 1916, I was sent for to see a multipara, aged 38, whom I found complaining of very severe headache, sickness, and feverishness. She said she had not been feeling well for some weeks, but had kept about her work until that day.

On examination I found that the patient was about seven and a half months pregnant, the foetal heart being quite audible. The symptoms were very indefinite at that time and the woman appeared to be suffering from some acute gastric disturbance. During the next few days, however, the pain in the head and the vomiting increased, while there slowly developed marked rigidity of the neck and back, with retraction of the head. The tongue was now thickly coated and the bowels were obstinate. The pupils were equal and reacted normally. The abdominal reflex was greatly increased, as were also the knee-jerks. The plantar response was doubtful in both feet; ankle clonus was once obtained with the right leg, but not with the left. The urine was examined and found to be normal in every respect, and this was always the case in repeated subsequent examinations. The temperature varied between 100°F . in the morning and 103° in the evening, while the pulse was usually about 80. The vomiting was by this time very frequent and severe, and the patient was quite unable to obtain any sleep. After four sleepless nights, during which time various hypnotics were tried, I gave her a hypodermic injection of heroin gr. 1/6 and hyoscine hydrobrom. gr. 1/100. This appeared to have a most beneficial effect, and the patient slept for five hours. This injection was repeated on several occasions, and although the amount of sleep obtained was never as great as after the first dose, yet each injection was followed by a certain period of sleep.

On the ninth day I performed lumbar puncture under a general anaesthetic, and found the cerebro-spinal fluid to be under great pressure. Slightly over three ounces of clear fluid ran away and this was found on bacteriological examination to be sterile. On recovering from the anaesthetic the patient was rather collapsed. Her temperature fell to below 95° where it remained for two days, and then it slowly rose to normal, never again going above 99° . The pulse-rate was not much altered, and it remained at about 80. There was an immediate improvement in the retraction of the head, which became less marked each day. There was a little vomiting after the anaesthetic, but this had ceased within 12 hours. The patient was still troubled with sleeplessness, but with the aid of chloral hydrate, gr. xx., this difficulty was overcome.

On the fourteenth day, five days after the lumbar puncture, the patient went into labour, and was rapidly delivered of a rather small but healthy male child. The puerperium was normal in every respect, and the child, after wasting a little for the first week, soon began to put on

weight. It is now four months since the child was born, and the mother, who is about the house again, only complains of rather frequent headaches.

It would have been most interesting to know the cause of this great increase in the cerebro-spinal pressure. Unfortunately there was some delay between the lumbar puncture and the examination of the fluid. This may account for the fact that the fluid was sterile. Several somewhat similar cases have occurred lately among soldiers in which the influenza bacillus has been found in the cerebro-spinal fluid, and it seems to me that this was most probably the organism in this case.

The most interesting points in the case appear to me to be: (1) The great improvement following lumbar puncture; (2) the beneficial effect of heroin and hyoscine in producing sleep; and (3) the healthy state of the child at birth and up to the present time.

Medical Societies.

MEDICAL SOCIETY OF LONDON.

Orthopaedic Principles and Methods in Military Surgery.

A MEETING of this society was held on Oct. 23rd, Lieutenant-Colonel D'ARCY POWER, the President, being in the chair.

Mr. DAVID McCRAE AITKEN gave a demonstration of cases illustrating *Orthopaedic Principles and Methods in Military Surgery*.¹ The demonstration consisted of a series of cases illustrated by lantern slides showing the X ray appearances, the deformities, the method of treatment adopted, and the results of the treatment. In many instances the lantern slides were supplemented by plaster casts, paintings, and the patients themselves in their present stage of treatment. The arrangement of cases was intended to point out that restoration of function can be secured in many cases by perseverance in gentle means when no such success could be obtained by any rapid measures. The first series of cases consisted of patients who had lost the head and neck of the humerus, and in some cases also the glenoid surface of the scapula. The method of treatment shown was continuous abduction of the arm in an abduction splint to allow adaptation of muscles and ligaments and the formation of an efficient false joint. The second series consisted of compound injuries to the elbow-joint demonstrating that persistent maintenance of the elbow in a flexed position gives the best opportunity for the restoration of a certain measure of movement, while any attempt at forcible movement would inevitably lead to further injury of what remained of joint surfaces and would induce a firm ankylosis. The third series illustrated points essential to, and faults which may occur in, bone-grafting operations to replace defects in the bones of the forearm. The wrist-joint was next dealt with and cases were shown which demonstrated the importance of dorsiflexion of the wrist at all costs, and the rapid recovery of movement in the fingers 10 days and three weeks respectively after wrenching into dorsiflexion with Thomas's wrench, followed by immobilisation of the wrist in plaster. The cases of injury of the lower limb illustrated the correction of errors of alignment in fractures of the long bones, including the correction of a case of traumatic coxa vara with a shortening of 3 inches which had been reduced to about 1 inch. The patient had also total paralysis of the sciatic nerve, which had been destroyed by the original gunshot wound. This was followed by a complete demonstration of the various stages of correction of a mal-united fracture of the middle of the shaft of the femur with shortening of over 2 inches, the result to day being a shortening of less than half an inch in a period of seven and a half weeks. The patient was at present walking in a Thomas walking calliper. Splints suitable for the gradual extension of flexed knees and the gradual flexion of knees stiff in extension were next shown. These were followed by a series of mal-united fractures of the leg and deformities of the foot which had been corrected by various methods. The speaker's experiences of

the correction of deformities and restoration of function in cases of trench-foot were then related. The mode of attack was, first, rest in bed and gradual correction with splints during the stages of extreme tenderness, massage to relieve pain being employed at the same time; secondly, more firm correction by moulding in plaster; and thirdly, a prolonged period of walking with the foot corrected in plaster. Throughout the whole demonstration the importance of maintaining muscular tone by means of massage, and especially by means of voluntary movement with the splints continuously worn, was given due attention.

Dr. J. B. MENNELL referred to conditions of fixation of joints in which movements and exercises led to no improvement, but great advantage followed rest in suitable positions. He spoke of the importance of keeping in function those muscles and joints which were uninjured, having often encountered cases where inattention to this rule had caused more difficulty in regaining movement in the unaffected than in the affected region. It was advantageous, wherever possible, to attempt similar exercises synchronously on the two sides, for the muscles on the affected side would often begin involuntarily to imitate the movements of those on the sound one.

Dr. D. M. BARCROFT spoke of the good results which followed the application of the same rules as those demonstrated by Mr. Aitken in obtaining recovery in muscles paralysed after poliomyelitis.

Mr. R. H. JOUELYN SWAN agreed in the main with Mr. Aitken. He recommended excision in cases of recent serious destruction of a joint accompanied by suppuration. Like Mr. Aitken, he had experienced great difficulty in obtaining recovery of function in cases of hallux rigidus and hallux valgus.

Reviews and Notices of Books.

Arboreal Man.

By F. WOOD JONES, M.B., D.Sc. Lond., Professor of Anatomy in the University of London (London School of Medicine for Women). With 81 text figures. London: Edward Arnold. 1916. Pp. 230. Price 8s. 6d. net.

IT may be said at once that the Arris and Gale Lectures, delivered by Professor Wood Jones at the Royal College of Surgeons of England in 1915 and 1916, and which now appear in book form with the title given above, constitute an important and original contribution to our knowledge of the evolution of the human body. The author has succeeded in doing a thing which many scientific men regard as impossible—he has presented a technical problem in a form which is at once new and acceptable to experts and yet which can be understood by the novice with ease and interest.

In the opening chapters Professor Wood Jones attacks the prevalent conception—one which has become traditional—that man's body represents the supreme product of creation or evolution. He passes in review the various structural parts of man's limbs—the hand, the forearm with its adaptations for supination and pronation, the shoulder with its well-developed clavicle, the foot, leg and hip—and at every point he meets with structures which have no counterpart in any mammalian order except that to which man belongs—the Primates. To find those structural and functional characters which distinguish the human and simian limbs he finds it necessary to descend to the very lowest of land-living vertebrates—the “clambering water newt” and the slow-moving and primitive tortoise. We are justified, he holds, in considering that the limbs of such primitive forms must be accepted as representing for us the structural condition of the earliest mammalian limb—the pro-mammalian forms whose fossil remains are found in deposits of the Triassic epoch. He then proceeds to answer the question: How is it that the various elements of the ancestral or pro-mammalian limb have been preserved in human limbs? His answer is that the Primates must have broken away from the early land-living mammalian stock while the primitive bones and muscles were still preserved in that stock, and that the primitive elements proved useful and were preserved in that particular form which adopted an arboreal life and used the hand and foot as grasping organs. The primitive plan on

¹ The paper will be published in full in THE LANCET.

which the limbs of man are built can only be accounted for by supposing that man's ancestry spent a long pilgrimage on the trees. It was during his arboreal phase that the vast majority of those anatomical characters which we regard as adaptations to man's upright posture were evolved.

"The upright poise of man," writes the author, "has been lauded as one of his greatest distinctions. This praise of human uprightness has, without doubt, been carried to absurd extremes, so also has the tendency to ascribe to that same uprightness a multitude of human weaknesses and disabilities. This visceral uprightness is no new thing, the readjustment has been gradual, and some measure of it has been very long established. It is easy to overdo the praise of the poise. It is equally easy to overdo the condemnation of it as a cause of many human ills."

The recognition of very primitive structural characters in man's body is no new discovery; it is one which the late Professor Klaatch emphasised. What is new is the complete and systematic method by which Professor Wood Jones has attacked the problem and the manner in which he has brought to its solution an intimate and accurate knowledge of living moving things. For him the real solution of an anatomical problem of any part lies in a painstaking inquiry as to the action of that part in the living animal. In this respect his book stands alone amongst treatises of an anatomical nature. This attitude is particularly well exemplified in his treatment of certain relations to the reproductive system. The uterus of the higher Primates is peculiar in that its cornua are greatly reduced and its body greatly enlarged; as a rule only one offspring is produced at birth; the mammae are reduced to two in number and are situated on the pectoral region; the young is nursed. At first sight these seem isolated facts, all of them inexplicable. To Professor Wood Jones all are the result of an arboreal environment. A single baby ape is as much as the mother can manage at once; with a single pregnancy the uterine cornua become unnecessary; two mammae become sufficient. They are pectoral in position because the young cling to the breast and are nursed there. The mother can nurse the young because the hands are specialised for grasping and holding.

The section of this book which is most likely to appeal to the general reader is that which deals with the evolution of the human brain. The basis on which the author builds is that provided by the classical researches of Elliot Smith. Cerebral anatomy and comparative as well as human psychology are treated as interdependent matters, and the success of this part of "Arboreal Man" lies not only in the happy conjunction of aims and methods but in the many original observations which Professor Wood Jones brings to the elucidation of complex problems. It is a book which will produce discussion and lead to a further increase of knowledge.

A Text-book upon the Pathogenic Bacteria and Protozoa, for Students of Medicine and Physicians.

By JOSEPH MCFARLAND, M.D., Sc.D., Professor of Pathology and Bacteriology in the Medico-Chirurgical College, Philadelphia, &c. Eighth edition. London and Philadelphia: W. B. Saunders Co. 1915. Pp. 878. Price 18s. net.

WE have in past years commented favourably upon previous editions of this text-book and have no reason to alter our views in the presence of the volume before us. It gives a very complete account of the various infective organisms—animal, vegetable, and doubtful, for the position of the spiral organisms is not yet established—preceded by general considerations on immunity, technique, and classification. Vaccines and serum reactions are also dealt with in general and in particular. The arrangement of the chapters on individual parasites is, as was previously noted, somewhat arbitrary, the protozoa not being grouped together, but scattered among the bacterial parasites. The subject-matter in the present edition has been brought up to date, the size of the pages has been increased, and small type has been employed for technical details and matters of minor importance to the general reader. The book is fully illustrated and well indexed, and forms a very commendable manual of micro-parasitology.

New Inventions.

IMPROVED OBSTETRIC FORCEPS.

THE obstetric forceps here illustrated incorporate some novel features. The cephalic portion of the blades (Fig. 1) are mobile—an arrangement that enables an automatic moulding and rotation of the head to take place without

FIG. 1.

interfering antagonistically with the normal uterine contractions. The blades are so constructed that, by turning the bottom key upwards, one or both can be either fixed or liberated at the will of the operator. It is well known that in the high operation a rigid forceps when seizing an asynchronously placed head at the brim will tend to pull it down in this position at the expense of much unnecessary force and labour on the part of the obstetrician. Mobile blades in

such cases will obviously favour a gradual correction which the uterine contractions (= *vis medicatrix uteri*?) are endeavouring to establish. To remedy this defect, Tarnier introduced his axis-tractor forceps. The freedom of the forceps to follow the movements of the head constitutes a great advantage of his instrument. The present forceps, with their mobile blades, will favour a natural rotation in practically any line of traction; the blades when free will automatically adapt themselves to the sacral curve. (Figs. 1 and 2.) By the fixation or liberation of one or other blades plus light traction an occipito-posterior or mento-posterior position may be made to rotate anteriorly. To sum up, the advantages

are: 1. The movable blades allow the head to mould and adjust itself to the larger pelvic diameters of the parturient canal without the resistance of the ordinary fixed forceps. 2. Traction need only be a straight pull—not necessarily

FIG. 2.

backward (in high operations), hence no undue stretching of the perineum and lacerating of the soft parts. 3. By the liberation of one or other blades the head in an occipito-posterior or mento-posterior position may be made to rotate anteriorly. 4. They combine the advantages of an

axis-tractor minus the complicated lever mechanism and its difficult application. 5. The

blades can rarely slip, even when faulty traction is applied. The instrument has been designed for me by Messrs. Weiss and Son, 287, Oxford-street, London, W.

Barton-on-Humber.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 4, 1916.

The Effects of Fatigue on Industry and Efficiency.

THE effects of fatigue on industry and efficiency have been the subject of many articles and communications in our columns since this nation began to apply itself seriously to the business of winning the war, but the physiological aspect of these effects has never been put more aptly than it was last week in the Chadwick lecture delivered by Professor WILLIAM STIRLING before the Royal Society of Arts. Fatigue may be due to overwork of the whole organism or of its individual parts, and, as Professor STIRLING pointed out, both objective and subjective symptoms have to be reckoned with and the appropriate tests applied. Fatigue is a universal concomitant of life, but the diminished output associated therewith is not necessarily accompanied by any sense of fatigue recognisable by the worker. The loss of excitability may be unconscious, and, indeed, in mental work the sense of fatigue may be present when facts show that an actual increase of work is being done. This apparently illogical happening is observed in certain workers when within sight of the end of the task; feeling that so far all has gone on well, and noting that only for a space of time will the strain be continued, the worker finds that he can make a last but great call upon his unsuspected reserves—like the long-distance runner he can sprint to the tape. The phenomenon exactly contradicts the more common experience that in the closing stages of work the output dies quickly down and time is wasted. This is the difference between a conscientious worker, who takes an interest in and feels responsibility for his work, and the beast of burden.

Professor STIRLING attributed the physiological process of fatigue to two causes: the using up of organic forces or energy, and the wear and tear of the organs which are overworked, so that matter and energy are consumed while restitution does not keep pace with work. These words, though there is nothing whatever novel in their teaching, which is closely supported by the report of Professor A. F. S. KENT to the Chief Inspector of Factories upon the association between fatigue and output, call for particular attention at the moment. We all know that to keep our Army at its present state of efficiency, and to replace the wastage which, however carefully thought out the management of our forces may be, remains terribly large when such masses of men are concerned, a regular influx of recruits is required from

day to day. The age-limits for recruiting have more than once been extended as our operations have grown in magnitude, and a rigorous process of inquiry into the various headings under which exemption can be obtained from military service is proceeding to-day. This is an absolute necessity of the situation in which we stand—a very strong situation, be it remembered, if all classes of the community can be brought into line for extended coöperative effort. Those who would point to the overwork which various "combing out" processes may entail upon the residue are apt to forget that to be a soldier in time of war, and in such a war as that wherein we are involved, is also a very fatiguing occupation; and they should remember not only this fact, but also that the work of the soldier, like that of the civilian, will assuredly be subject to physiological laws and will decrease in quality and quantity if proper intervals of rest are not forthcoming. At this moment the physical conditions of our Army are of paramount importance to the nation, while the authorities are making their net as inclusive as possible. But it is necessary that recruiting should be carried on under a vigilant medical eye, for there is no economy in paying a man to fight for his country whose physical condition is so bad, or rapidly becomes so bad, that time and money have to be spent in trying unsuccessfully to bring him to a reasonable standard. The stories which have appeared in the daily press now and again detailing the recruiting of grossly unfit persons, must not be taken as a fair sample of what is going on generally; it is inevitable that all such instances of negligence or of pig-headedness should obtain publicity and should thereby gain an importance to which their numbers do not entitle them. But with our growing knowledge of the effects of fatigue upon the organism and upon the resulting work, we must all see the necessity of not supplying to the Army material that cannot reasonably be depended upon to stand the strain to be exacted.

It will be remembered that last year a committee was appointed with the concurrence of the Home Secretary and under the chairmanship of Sir GEORGE NEWMAN, the principal medical officer to the Board of Education, with the following reference: "To consider and advise on questions of industrial fatigue, hours of labour, and other matters affecting the personal health and physical efficiency of workers in munitions factories and workshops." This committee has made a number of valuable reports to the Ministry of Munitions, the gist of which was to point out that the management of our factories has hitherto been less based on experimental science than has been the case in the business concerns of Germany; and the scientific and physiological aspects of fatigue as described in Memorandum 7 show that much more could be done to deal with the problems of industrial fatigue and modify the ill-effect and reduced efficiency of the want of proper organisation. Strenuous efforts, we have every reason to believe, have been made to remedy this condition of affairs, and it is with the plight

of the munition workers that we have so far been most concerned; but it is not here probably that the effects of shortage of man power will be first felt, for the risk of depleting the munition factories and reducing their output is so obvious that it will not be taken. A large host of clerks, typists, and other sedentary workers have been employed since the war broke out in operations requiring unremitting attention and for spells which have no parallel for similar occupations in times of peace. Here women have come forward and relieved male labour to a very appreciable extent, but here also will the first effects of drastic recruiting be seen. Great responsibility may be thrown in this connexion upon the civilian medical profession—a sadly reduced body of workers. For from them will much help and information be expected if any general investigations should be carried out with a view of arriving at conclusions based upon larger evidence than any yet forthcoming; and it seems to us that some more far-reaching inquiries than any which have hitherto taken place will have to be instituted into the effects of fatigue on industry and efficiency.

The Prohibition of Alcoholic Beverages.

A MEMORIAL which is in preparation, and which has already appeared in the public press with a thousand influential signatures attached, asks the Government to suspend all drink licences throughout the kingdom for the period of the war. The appeal is based on a plea to put the nation at its full strength by removing "a danger which holds back the hour of early victory and throws a shadow over the vision of peace." With the weakening power of alcohol removed, the signatories claim that the national effort against the enemy will gather increased strength. It is not drunkenness alone which endangers the supply of munitions, but, says the memorial, "the constant sapping of men's energies by alcohol." The suspension of the liquor traffic during the war and the conversion of the public-houses into houses of refreshment will, it adds, quicken up the civil and fighting populations, will raise new fire of resolution in the people, and will give to millions the first opportunity they have ever had of breaking old habits of weakness and forming new habits of strength. The appeal is not made by temperance reformers as such, but by thoughtful men in every sphere of business and professional life.

The sapping of men's energies by alcohol is, of course, a medical commonplace, and there cannot remain many people who refuse to endorse the statements in the memorial regarding this danger. If we accept it as critical at the present time we can only picture two classes from whence opposition to the suspension of the traffic will come. First there are some—but we cannot think many—who do not believe that self-control can be strengthened by limitation of temptations to excess. A study of the rapid fall in convictions for drunkenness in nine English cities and towns

since the restrictions imposed by the Central Control Board may help to convince them to the contrary. But those who are financially interested in the production or sale of liquor have in many instances a private code of self-control so strict that it is not easy for them to comprehend the weakness of others. Secondly, there are some who believe that the consumption of alcohol has advantages which compensate for the admitted dangers. For the latter class the case may be stated thus: 'Alcoholic liquids may be taken as food, medicine, or luxury. It is established that about one ounce of absolute alcohol is the limit which can be burned up in the body within a period of 24 hours without paralysing or narcotic effect and without the appearance of unchanged alcohol in the excreta, and one ounce of alcohol supplies about as much fuel as one ounce of margarine—that is, 200 calories. Now one ounce of alcohol, as we pointed out many years ago, costs in the form of cheap spirit 1½d., in the form of beer 3d., in the form of heavy wines 4d. to 6d., in the form of light wines about 1s., and to these prices some 40 per cent. must be added during war-time. One ounce of margarine costs less than ½d. Alcohol in the quantity which can be taken as food is a wasteful food. There is little doubt in the minds of hospital staffs and committees about the value of alcohol as a drug; it has its place, but in the past it was over-estimated. The quantity of alcohol used in treating the sick poor may fairly be taken as a criterion, and a recent example is suggestive. In reply to a Parliamentary question on Oct. 18th last it was pointed out that the cost of alcohol administered to patients at Guy's Hospital had been reduced from £1576 per annum to £151, at Leeds Infirmary from 6s. 6d. per head per annum to 2d., and at Wandsworth Infirmary from 5s. 3d. per head per annum to half a farthing. As a drug, therefore, alcohol is found to-day to have a much restricted application. But we are here leaving out of count its use as an adjunct to digestion, and one of the weak points in the arguments of the strict teetotaler has always been his inability to believe in the existence of such an effect of a small dose of alcohol in a pure and agreeable form. In normal times the claim for the use of alcohol as a luxury cannot be passed over. One of our great thinkers stated the case reasonably when he said that wine used in moderation seems to add to the agreeableness of life, and whatever adds to the agreeableness of life adds to its resources and power. With the major part of our young manhood serving under conditions in which life is the reverse of agreeable, those who remain can hardly be wrong in forgoing this agreeableness as part of their contribution to the cost of the war. If the abstinence produces real ill-effects, then will be the time to fall back upon alcohol—alcohol as a drug.

For the useful employment of alcohol, when prohibited as a beverage, there need be no fear. The memorialists look to the cessation of its manufacture and the utilisation of its raw materials—potatoes and grain—as immediate sources of food-supply. And true it is that there is an inevitable loss of energy in the conversion of these more highly organised bodies into the simpler alcohol:

only some 60 per cent. of the energy in the barley grain or the potato flour remains in the resulting beer or spirit. But if for the present some of the brewing and distilling must go on there are other ways in which ethylic alcohol can be employed. Doubtless a large proportion of the available production is already used directly or indirectly in the manufacture of munitions. But there are a thousand different directions in which alcohol is of service to mankind in the arts and manufactures. It is known that in Germany before the war one-half of the alcohol produced was consumed for various technical purposes. Alcohol is, next to water, the most valuable known solvent, and it has over water the great advantage of a lower boiling point. The shortage of pure alcohol in pharmacy for the preparation of drugs, and in all kinds of laboratory proceedings, is a serious evil, and the high price consequent on the duty which must be paid for its potable employment prejudices its scientific use. Alcohol, if prohibited as a source of mischief or an evidence of luxury to the community, may remain in part as an indirect blessing.

Annotations.

"Ne quid nimis."

UNQUALIFIED TREATMENT OF VENEREAL DISEASES.

SEVERAL correspondents have written urging the necessity of an active campaign for the suppression of the treatment of venereal diseases by unqualified persons. The Royal Commission was very wide-awake to the dangers of the present state of affairs, including the share therein contributed by druggists, herbalists, and advertisement of all sorts. Section 190 of the Report runs, "unqualified practice in these diseases is a disaster, and its existence is a main hindrance to the eradication of venereal disease." But the Commission also realised that the education of the public and the provision of free treatment would tend to diminish the evil of quacks, instancing the fact that in the Army, where instruction and treatment are well given, there is hardly any resort to unqualified practitioners. The Commission therefore concluded that penal measures against unqualified practice would at present prove inoperative, and decided to press forward with the utmost speed the positive measures of systematic free treatment and enlightenment—in short, not to prohibit the sale of inferior goods until a better brand was available. At the same time, in common with the Select Committee on Patent Medicines, the Royal Commission decided that all advertising of venereal nostrums ought to be stopped at once. Lord Sydenham emphasised the need for the suppression of quack advertisements in his presidential address on the work of the National Council and again last week at the Mansion House meeting, and the matter gained at once in importance by a statement made by the President of the Local Government Board later at that meeting. Mr. Long's words were: "Lord Sydenham said he hoped we would deal with the development of quack medicines and the treatment by quack doctors. If public opinion supports

a policy of that kind, and if I can find—which, let me say, I have not yet done—a real working proposal which would have those effects, I shall be ready to do my best to carry it through Parliament." This offer of Mr. Long's should be taken up at once, and no time lost in supplying him with a working proposal for dealing with the advertising of remedies for venereal diseases. All are agreed on the necessity for its prohibition. It should not require any great ability to draw up a simple measure embodying the proposal, which could then come into immediate force. With his wares no longer forced on public attention, the unqualified practitioner would compete to less advantage with the treatment centres. The penalising of the dwindled unqualified practice might then be dealt with at a later time, when the authorised schemes of treatment will have proved themselves efficient.

THE CONSERVATION OF MYDRIATIC DRUGS.

ATROPINE, even of absolute purity, is not a single chemical substance, but is to all intents and purposes an intimate mechanical mixture of right- and left-handed components, these being the isomeric dextro- and lævo-hyoscyamines, which differ greatly in physiological effect. Mr. H. R. Jensen, M.Sc., writes from the laboratory of Messrs. Evans, Sons, Lescher, and Webb, Limited:—

The purest atropines of commerce, of course, contain these constituents in almost precisely equal quantities—the solanaceous plants never—but samples have been examined in this laboratory containing as much as 59.5 per cent. lævo- and 40.5 per cent. dextro-hyoscyamine, which specimens are only undesirable from the standpoint of therapeutic uniformity. With the prevailing scarcity of atropine the advantages of l.-hyoscyamine may be emphasised. The greatest use for this drug is that dependent on its mydriatic property, and Cushny,¹ in exact weight experiments by injection into a cat, demonstrated that 0.045 mgrm. of lævo-hyoscyamine (97.4 per cent. optical activity) had quite the same pupil effect as 0.55 mgrm. of dextro-hyoscyamine, and hence was twelve times the strength of the latter, which makes the lævo- theoretically 1.84 times the mydriatic strength of atropine—he actually observed that 0.025–0.03 mgrm. of lævo-hyoscyamine produced the effects of 0.06–0.0625 mgrm. of atropine. The salivary gland intensity was shown to be of a similar order, and the cardiac effect even greater. But atropine was found to possess greater stimulating power on the spinal cord of the frog owing to the d.-hyoscyamine having a stronger specific strychnine-like action on the cord. Laidlaw² later showed that by using super-pure derivatives of the highest optical activities, the intensity of l.-hyoscyamine could rise to 100 times that of dextro-, and thus one of l.-hyoscyamine would be equivalent to 1.98 of atropine, an increase in strength quite out of proportion to the slight increases in purity, indicating dynamic or other influences resulting in two mixed drugs not giving the mean effect of the constituents.

In view of the fact that raw materials now available at least ensure a supply of l.-hyoscyamine, which can only be transformed into the much less active atropine with both chemical and physiological losses, this aspect may become more important than the actual costs of production. Mr. Jensen states, further, that two large samples of Egyptian henbane (*Hyoscyamus muticus*) were found by him to actually yield at least 83 per cent. of their alkaloids as l.-hyoscyamine of full activity, which content scarcely depreciated in the processes employed for isolation. Specimens of salts prepared therefrom having a specific rotation for the basic ion of -31.7° (i.e., an activity of

¹ Pr. Amer. Physiol. Soc., 1903, 14; J. Physiol., 1904, 30, 176.

² Tr. Chem. Soc., 1909, 95, 1969.

97.3 per cent. lævo-, or similar to Merck's), were found in systematic use by a prominent ophthalmologist to have special advantages, it being concluded that for ordinary clinical use locally, 0.5 per cent. solutions of the salts had an intensity indistinguishable from 2.0 per cent. solutions of atropine sulphate. It may be that in the transient action of drops, rapidity of action is a further factor in so enhancing the intensity. Mr. Jensen concludes—

Solutions kept a month or two showed no appreciable loss of activity, and although auto-racemisation is known to occur in the presence of moisture, apparently an equilibrium or great retardation occurs before this has proceeded far. Finally, the use of l-hyoscyamine, even in 1 per cent. solutions, has so far been unattended by those symptoms of toxicity which frequently accompany atropine. The waste of mydriatic material is obvious, and that it is due not to the restraints imposed by former prices, but perhaps to the conservatism of medicine is shown by the following pre-war values: atropine 1-1.3, l-hyoscyamine (95 per cent.), 1.9; super l-hyoscyamine, 8-12, which latter ultra refinement can be seldom required. The miscalled "amorphous hyoscyamine," which has specific uses, had the value 6. There is no reason why permanent supplies of l-hyoscyamine should not eventually be available to any extent demanded by the medical profession.

In view of the natural variation in the l-hyoscyamine content of belladonna, accentuated by numerous methods of obtaining its galenical preparations, an advance in therapeutics would, no doubt, occur if this drug were controlled not only as to its so-called "atropine" content, but also as to a definite proportion thereof of the much more active l-hyoscyamine.

SUPRARENAL ATHEROMA AND ITS TREATMENT.

SOME experiments have recently been carried out by Dr. Fabio Marabotto, and published in *Annali dell' Istituto Maragliano*, which, although in a preliminary stage, throw light on the pathology of arterio-sclerosis. By making use of an aqueous solution of suprarenal capsule one part to three of physiological salt solution, Dr. Marabotto found that intravenous injections of $\frac{1}{4}$ to $\frac{1}{2}$ c.c. caused marked aortic atheroma in rabbits. On the other hand, no such effect was produced either by subcutaneous injection or oral administration. A second series of experiments were undertaken to investigate the action of a suprarenal toxic serum, when administered simultaneously with suprarenal extract, on the condition of the aorta, in other words to ascertain the behaviour of the animal organism with regard to the production of suprarenal atheroma when under the influence of treatment by suprarenal toxic serum. To obtain this serum, rabbits were inoculated with small repeated quantities of suprarenal emulsion for the space of a month, giving the injections every fourth day. After the last injection the animal experimented on was left quiet for 10 days and then bled. The collected serum, which separated spontaneously, was immediately inactivated by keeping it for half an hour at a temperature of 56° to 58° C., being then sealed in sterilised tubes and kept in ice. Alternate injections of suprarenal extract and the toxic serum, when the latter was given subcutaneously, gave rise to unimportant changes in the aortic coats absolutely not to be compared in their insignificant extent and intensity with those observed in animals subjected exclusively to intravenous administration of suprarenal extract. When under similar circumstances the toxic serum

was administered by the mouth very slight changes in the aorta were noted resembling atheroma, but more extensive and intense than when the serum was given subcutaneously. These results seem to give some indication of the possible benefit of injections of suprarenal toxic serum in the treatment of arterio-sclerosis, and we await with considerable interest the publication of Dr. Marabotto's further researches on the histological aspect of his experiments.

THE EDITH CAVELL HOMES OF REST FOR NURSES.

AN appeal has been issued on behalf of these homes, signed by Sir William Robertson, Lord French, Lady Haig, Lady Jellicoe, and others. As a beginning a freehold house, which would deal with the needs of about 100 nurses yearly, has been offered as a gift at Coombe Head, Haslemere, Surrey, provided that a fund sufficient for its permanent endowment as a suitable home can be raised. Donations should be sent to the honorary secretary, 25, Victoria-street, London, S.W. Messrs. Barclay and Co. are the bankers. We cannot conceive a worthier object for donations. "Of all the many shameful deeds," writes Sir Arthur Conan Doyle, "perpetrated by the Germans in the war, there has been none more cold-blooded, and therefore more odious, than the execution of the saintly woman, Edith Cavell." This feeling is universally held, and can be demonstrated in no more effective way than by subscribing to the foundation of Homes of Rest for Nurses, for the institution of these was the cherished hope of Edith Cavell.

CYANOCUPROL AND TUBERCULOSIS.

IN the August number of the *Journal of Experimental Medicine* some carefully planned experimental and clinical facts have been published by Dr. Gensaburo Koga on the value and effects of a substance called cyanocuprol upon tuberculosis. Both copper and cyanides are known to exert a powerful inhibitory action upon the tubercle bacillus. A compound of the two, however, unless specifically treated, will exert too active a lesional reaction, but a method has been evolved which will permit their bactericidal effects whilst checking too severe a tissue response. The first preparation employed was a specifically prepared solution of potassium cyanide; it was called solution A. Into guinea-pigs, 2 mg. of the human type of the tubercle bacillus were introduced under the skin on the left side of the chest, and observations were made on the duration of life, body weight, and changes in the various organs, especially the growth of the tubercle bacilli. These animals were used as controls and compared with others similarly infected, but which received hypodermic injections of the liquid. Control animals developed extensive tuberculosis, whilst of those treated with liquid A, 15 in number, two lived on in apparent health, five died of intercurrent accidents, one only showed progress in tuberculous lesions, whilst in the remaining seven all pathological changes were arrested. Next, the conjunctiva of the eye was experimentally infected and the same liquid A tested. In the control animal the infection was progressive, whilst in three animals treated with liquid A it was suspended. Liquids A and B (a slight modification of A) were now tested in a similar way in comparison with three other preparations at present regarded with favour as curative agents for tuberculosis—copper chloride, albumin-free tuberculin, and

iodotuberculin. Forty animals were used, ten as control. Liquid A was found to be the most efficient, although it did not completely heal the tuberculous lesions. After other experiments, which led to evolving an even more potent liquid, D, and also established the most suitable method of dosage and administration, this liquid, now called cyanocuprol, was tried in clinical cases. There are, of course, many difficulties in testing clinical effects with accuracy, difficulties not met with under experimental conditions. But as near an approach to accuracy as could reasonably be expected in the series of 63 cases of tuberculosis treated was obtained. Twenty-five cases are claimed as "cured," as shown by gain in body weight, temperature below 37° C., no or nearly no physical signs, bacillus-free sputum where previously bacilli abounded, and the patient being able to do regular work. Of the remainder, 22 improved, three died, and nine were still under treatment. The day after injection physical signs increased, which lessened about the eighth or ninth day. Repeated injections showed diminution of regional phenomena and often final disappearance. The results in five cases of tuberculosis of lymphatic glands were very good. The writer concludes that "the preparation greatly improves or apparently cures pulmonary and surgical tuberculosis in the first and second stages." He obtains beneficial effects in the third stage. The preparation must be given intravenously, though the manner of action is not yet entirely clear. In a paper published in the same issue by Dr. Morisuke Otani, further clinical results are published, this writer concluding that "cyanocuprol is markedly effective in tuberculosis and we believe that it will play an important part in clinical medicine." Both papers bear the mark of careful observation; the results are stated with studious moderation, and further observations will, we hope, be made on similar lines.

THE METROPOLITAN WATER-SUPPLY.

THE condition of the metropolitan water-supply during the month of July was satisfactory. The rainfall was 1.54 inch, being 0.77 of an inch below the average mean rainfall for that month during the previous 33 years. Both bacteriological and chemical examination of the raw waters showed on the whole an improvement, while the filtered waters yielded results better than their respective averages in each case. As regards typical *B. coli*, the filtered waters were practically sterile.

THE NATURE AND TREATMENT OF CARBON MONOXIDE POISONING.

Professor Yandell Henderson, of Yale University, has recently called attention in the *Journal of the American Medical Association* to a prevalent error as to the nature of carbon monoxide poisoning which leads to a corresponding error in treatment. The subject is important, for this gas is responsible for more deaths than all other poisonous gases taken together. The attraction of carbon monoxide for hæmoglobin is 250 times as strong as that of oxygen, but it is wrong to suppose that the resulting combination is permanent or that any lasting deterioration of the oxygen-carrying power of the hæmoglobin is produced. This may be shown by the following experiment. A drop of blood is diluted with water, a drop of very dilute ammonia is added, and the reddish-yellow solution is shaken

with air. One-third of this solution is poured off in a test-tube, while the remaining two-thirds are shaken up with illuminating gas. This portion assumes in a few minutes the cherry-red colour of carbon monoxide hæmoglobin. It is now divided into two parts, one of which is set aside in a third test-tube, while the other is vigorously shaken with air. In a few minutes this sample loses its cherry tint and regains the appearance of the normal blood set aside in the first test-tube. The "mass action" of the oxygen of the air has displaced the carbon monoxide from its combination with hæmoglobin. To all intents and purposes the blood is the same as if it had never been combined with the hæmoglobin. Similarly, when a man poisoned by carbon monoxide is brought into fresh air the combination of his hæmoglobin with the gas immediately begins to break up. The higher the percentage of oxygen in the air inhaled the sooner the gas is displaced. For 15 or 20 minutes after removal from the poisonous atmosphere (but not for more than half an hour) it is beneficial to administer oxygen, pure or with air, by an apparatus which does not allow rebreathing. Even when only air is breathed the mass action of its oxygen is usually sufficient to displace the greater part of the carbon monoxide in an hour or less, so that the oxygen-carrying power of the hæmoglobin is restored sufficiently for the patient's needs. This result is facilitated by the rapid breathing usually developed within half an hour if the patient is not too profoundly asphyxiated. Many never recover consciousness and die a day or two later. The prolonged coma and subsequent death are due to injury to the brain and other organs from insufficient supply of oxygen at the time the patient was breathing the gas. After the parenchymatous degeneration produced no method is known by which the affected tissues can be restored. As far as is known, nature does all that is possible. Authorities, evidently under the view now disproved that the coma is due to retention of carbon monoxide, advocate bleeding, infusion of oxygenated saline solution, and transfusion of blood. Such procedures Professor Henderson considers not only useless but injurious. He refers to the cases of three Filipinos of approximately the same age, weight, and physique overcome by illuminating gas while sleeping in a room. One was treated during the following day by withdrawing blood and injecting oxygenated saline solution, another by transfusion of blood, and the third only by nursing. Only the last recovered. Thus it appears that all that can be done in carbon monoxide poisoning is to perform artificial respiration if natural respiration is feeble or absent, to administer oxygen for half an hour (longer is useless), to keep the patient warm if his temperature has fallen, and to supply water to the system, preferably by Murphy's drip method.

THE Bradshaw Lecture of the Royal College of Surgeons of England will be given by Colonel Charters J. Symonds on Dec. 15th, the subject being "Gunshot Injuries of the Spinal Cord." Surgeon-General Sir G. H. Makins will deliver the Hunterian Oration on Feb. 14th, 1917. An autumn course of lectures for first-aid and ambulance students, by Professor A. Keith, on the Anatomy of the Human Body, is being given every Monday, Wednesday, and Friday during November (up to Nov. 27th), at 5 P.M. A second series is announced for January and February, 1917.

THE TREATMENT OF SEPTIC WOUNDS: CARREL'S STERILISATION METHOD.

AT a special meeting of the Surgical Section of the Royal Society of Medicine on Oct. 31st, with Colonel CHARTERS J. SYMONDS, the vice-president of the section, in the chair, Dr. SHERMAN, of Pittsburg, delivered a lecture on the sterilisation of wounds by the method of Carrel. He pointed out that it had been authoritatively stated that 75 per cent. of the deaths from wounds in war after the first 24 hours were due to sepsis, and that in the case of some wounds the percentage was even higher. He alluded to the various attempts, more or less successful, which have been made from time to time to sterilise septic wounds, and urged the need for the standardisation of the methods. Dr. Carrel, he said, had experimented with some 200 different antiseptics, ultimately deciding that Dakin solution was the best, especially in the modified form devised by Dr. Daufresne. The composition of the solution as now employed was stated to be as follows:

Materials required: Chloride of lime (containing 25 per cent. of active chlorine), 200 gm.; sodium carbonate (dry), 100 gm.; and sodium bicarbonate, 80 gm. The chloride of lime is put into a 12-litre flask with 5 litres of ordinary water, shaken vigorously for a few minutes, and left in contact for from 6-12 hours. At the same time the carbonate and bicarbonate of soda are dissolved in another 5 litres of water. The salt solution is then poured into the flask containing the macerated chloride of lime, and the mixture, after being shaken, is stood to allow the calcium carbonate to be precipitated. After about half-an-hour the liquid is siphoned off and filtered through a double paper to render it clear. It should then be kept in a dark place.

To obtain certain results the exact solution must be employed, and it is especially important that there should be no free caustic alkali, and it must contain not less than 0.45 per cent. and not over 0.5 per cent. of sodium hypochlorite. With less than 0.45 per cent. the fluid is not sufficiently active, and with more than 0.5 per cent. it is irritant. The original Dakin solution was said to contain 0.6 per cent. The action of the solution is most satisfactory if used in the first 24 hours after the infliction of the wound, but it is also of very great value even if employed much later, though necessarily the time taken in sterilisation is longer.

The gist of Dr. Sherman's address is as follows:—

Although the modified Dakin solution is of immense value, Carrel holds that the technique to be employed is of still more importance. The apparatus employed consists of a glass flask, graduated, to contain the Dakin fluid; from this comes a rubber tube, ending in a small glass tube, to which can be attached one or more rubber tubes. Each of these tubes is closed at the end, and in the sides of the tubes many small openings are made about a centimetre apart. The skin of the part is cleansed and painted with solution of iodine, and this is done whether the wound is recent or late. All foreign bodies are removed. The wound is laid open so that all parts of it may be reached, and the rubber tubes are passed into all the recesses of the wound; pieces of gauze are placed lightly round and between the tubes, so as to separate them, and at the same time the gauze will assist in retaining the solution in the wound, but the wound is not to be "packed." The Dakin solution is then allowed to flow from the container into the wound, and passing from the tubes it fills the wound completely. The wound should be refilled with the solution every two hours and re-dressed every day. The effect on the wound is striking. At first the number of microbes present is very great, in fact it may be called infinite; and many polynuclear leucocytes are present. But as the days go by the number of microbes steadily diminishes until very few are present, and when only one bacterium can be found in five ordinary fields of the microscope on five successive days the wound may be regarded as practically sterile, and it will be safe to employ sutures, for no suppuration will ensue, and not even a stitch abscess will develop. The sterility of the wound is strikingly shown by the fact that it is quite safe to plate compound fractures which have been sterilised in this way. If necrosed bone is present in a wound and cannot be removed it will not be possible to sterilise the wound. The method is not applicable to the eye or to the peritoneal cavity; and the solution cannot be injected into veins.

Dr. Sherman gave particulars of many cases in which the method had been employed, and said that the mortality had

been greatly reduced, and that amputations had become very much less frequent. Especially he claimed that the time taken for the complete healing of a wound could in this way be greatly shortened, saying that wounds which otherwise took months to heal healed under his technique in as many weeks. The percentage of failures was small, yet in order to obtain the best results the nurses and the assistants must be carefully trained.

The lecture was illustrated by a large number of lantern slides of photographs, some of which were coloured, and by skiagrams, showing clearly the technique employed and the results obtained.

In the discussion which followed the lecture, Sir W. WATSON CHEYNE said that the illustrations depicted results such as had not been obtained before. The paper coincided with his view that the only likely way to obtain good results was by the use of antiseptics.—Mr. JOCELYN SWAN held that the mechanical effect of the treatment was largely responsible for its success. He thought that the best results followed alternate treatment by hypochlorite and hypertonic salt solution. His experience of the progress of wounds which arrived in England after secondary suture in France was not satisfactory; not infrequently they had to be reopened.—Colonel CHARTERS SYMONDS hesitated to ascribe all the benefit to the hypochlorite solution; many other antiseptics would accomplish the same thing, but the hypochlorite method might be quicker. The results in compound fracture were certainly better than those obtained at base hospitals by other methods. He was satisfied that intermittent was better than continuous application of antiseptics.

CONTROL OF VENEREAL DISEASES.

THE BOROUGH OF PORTSMOUTH, SCHEME.

PORTSMOUTH is to be congratulated on being first in the field with a scheme for the control of venereal diseases, and we understand that the initial difficulties have been got over and only the formal approval of the Local Government Board remains to be obtained. The principal points of the scheme, which has been drawn up by Dr. A. Mearns Fraser, medical officer of health of Portsmouth, on the instruction of his health committee, are as follows:—

(1) The treatment will be carried out at the Royal Hospital under the direction of a specially trained medical officer. As there may be temporary difficulty in getting a full-time officer, it is proposed for the present to appoint Captain A. Campbell, R.A.M.C. (T.), who is doing similar work at the Hulsea Military Hospital. To commence with, the clinique is to be open on three afternoons and evenings a week, female patients being seen from 3.30 to 5 and male patients from 6 to 7.30. Two beds will be provided for each sex. The treatment is to be free to every patient without distinction. The medical officer and staff to be appointed by the Hospital Committee of Management, subject to approval of the Local Government Board.

(2) Laboratory facilities are to be provided at the Royal Hospital available for the medical officer in charge of the treatment centre, for poor-law and other medical officers, and for medical practitioners generally. The need for a properly equipped pathological laboratory has long been felt in Portsmouth. At the present time all pathological material has to be sent to London for examination, and the provision of a competent pathologist on the spot would give the much-needed opportunity for direct consultation between the medical man and the pathologist. For the present the part-time services of Captain J. A. D. Radcliffe, R.A.M.C., could probably be obtained.

(3) Salvarsan or its substitute is to be issued free to medical practitioners by the medical officer of the treatment centre and by the medical officer of health.

(4) Apparatus for collecting material for examination from suspects is to be obtainable free of charge by medical practitioners on application either at the town-hall or at the treatment centre.

(5) A committee is to be formed, including representatives from the various public bodies and voluntary agencies, to advise the council in regard to measures for disseminating information as to the scheme as well as for the control of venereal diseases. The suggestion is made that the local medical committee should appoint representatives to assist the committee in addition to the three medical men now serving on the health committee.

Emphasis is laid on the intention to observe the strictest confidence in regard to persons attending the treatment centre. Their names and addresses will be required by the

medical officer solely for the purpose of communication with them in connexion with their treatment, and under no circumstances to be divulged to any third person.

Dr. Mearns Fraser has made a provisional estimate of the cost of such a scheme for the first year. Portsmouth has over a quarter of a million inhabitants, and is, to boot, an important naval and military centre. The provision must therefore be adequate. The expenses come under two heads: (1) the adaptation of suitable premises at the Royal Hospital, together with the necessary instalment of apparatus and instruments; and (2) the annual maintenance. The Royal Hospital authorities did not propose to make any profit out of the scheme, and the following estimate is considered to be the outside cost of treatment:—

1. Adaptation of premises, £17; purchase of instruments, £60; total, £77.
2. Maintenance for one year, £40; laundry and cleaning, £50; fuel, heat, and lighting, £5; domestic, £40; general administrative charges, £100; total, £235.
3. Payment of medical officer at rate of 10s. per hour, not exceeding £25 per month, £300.
4. Nurses and orderly, £250.
5. Drugs, including salvarsan issued to practitioners, £200.
6. In-patients' board, £30.
7. Cost of pathological laboratory facilities, fitting of room, water, gas, &c., £50; appliances and instruments, £120; total, £170.
8. Payments for pathological reports at rates to be agreed upon, minimum 100, £150.
9. General: Apparatus for collecting material, printing, post, literature, lectures, &c., £50.

Grand total, £1462.

Of this expenditure, as Dr. Mearns Fraser points out, the council will only bear 25 per cent., the Local Government Board being responsible for the remaining 75 per cent. Notwithstanding the claims of economy at the present moment, he advises the council to undertake the additional £300 a year without hesitation.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

MEETING OF COMITIA.

A COMITIA was held on Oct. 26th, Dr. FREDERICK TAYLOR, the President, being in the chair.

The following candidates having passed the required examination were admitted Members of the College: Edgar Douglas Adrian, M.B. Camb.; James Froude Flashman, M.D. Sydney; and Charles Putnam Symonds, L.R.C.P.

Licences to practise physic were granted to 89 candidates who had passed the necessary examinations.

A letter was received from Dr. W. Pasteur resigning the office of censor owing to his proceeding to France on active service. Dr. Sidney Phillips was elected a censor.

The following resolutions were passed:—

1. That in the opinion of this College administrative measures for the diagnosis and treatment of venereal diseases will only attain their maximum effectiveness in protecting the public health when the treatment of such diseases by unqualified persons is prevented by law.
2. That it is desirable that the recommendations 58 (iii.) of the Patent Medicines Committee of the House of Commons, endorsed by the Royal Commission on Venereal Diseases, should at once be carried into effect.
3. That a copy of the above resolutions be sent to the Prime Minister, to the Home Secretary, and to the President of the Local Government Board.

The President was re-elected a member of the Committee of Management.

The PRESIDENT drew the attention of the College to the fact that the 400th anniversary of the foundation of the College will occur in 1918.

A report dated Oct. 3rd was received from the Committee of Management which announced: (1) That the Grammar School, Ilkley, had been added to the list of institutions recognised by the Examining Board in England for instruction in chemistry and physics; (2) that the University of Allahabad had been added to the list of Universities recognised by the Examining Board in England, and that graduates in medicine of the University be admissible to the Final Examination of the Board under the conditions of Paragraph IV., Section III., of the Regulations.

After some further formal business the PRESIDENT dissolved the Comitia.

THE SERVICES.

ROYAL NAVAL MEDICAL SERVICE.

To be temporary Surgeons: G. E. Burton, S. N. Scott, J. E. Phillips, S. R. Johnston, A. H. Flannery, and J. R. B. Robb.

The following appointment has been made:—Temporary Surgeon: D. J. Max to *Vivid*.

ARMY MEDICAL SERVICE.

Temporary Colonel H. M. Rigby (Captain, R.A.M.C., T.F.), having resigned his appointment as Consulting Surgeon, relinquishes his temporary commission.

ROYAL ARMY MEDICAL CORPS.

Temporary Lieutenant-Colonel E. A. Hanly relinquishes his commission on account of ill-health.

Majors C.A.M.C. to be Temporary Lieutenant-Colonels: A. B. Osborne and C. H. Gilmour.

Temporary Captain A. C. Renwick relinquishes his commission.

Captains C.A.M.C. to be temporary Majors: G. P. Howlett and H. Smith.

To be temporary Captains: Lieutenant A. D. Dias, C.A.M.C., and Hon. Major C. J. Stewart, C.A.M.C.

SPECIAL RESERVE OF OFFICERS.

Supplementary to Regular Corps or Units.

Lieutenants to be Captains: J. F. W. Meenan, D. H. Paterson, G. Irving, C. A. Whittingham, G. C. L. Woodroffe. A. L. V. Davin to be Lieutenant.

TERRITORIAL FORCE.

London Mounted Brigade Field Ambulance: Captain T. H. Chittenden to be temporary Major.

West Lancs. Field Ambulance: N. J. Allan to be Lieutenant.

London Sanitary Company: Lieutenant L. Griffiths to be Captain.

TERRITORIAL FORCE RESERVE.

Captain K. S. Storrs and Captain B. N. Ash, from Attached to Units other than Medical Units, to be Captain.

SOCIETY OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The annual general meeting of the Fellows and Members will take place at the College, Lincoln's Inn-fields, W.C., on Thursday, Nov. 16th, at 3 P.M. The following resolutions have been sent in on behalf of the Society:—

1. That this Thirty-second Annual Meeting of Fellows and Members again affirms the desirability of admitting Members to direct representation on the Council of the College, which as now constituted only represents those Members who also hold the Fellowship; and that it does so in order that the constitution of the Council of the Royal College of Surgeons of England shall be in keeping with modern ideas of true representation.
2. That as the Royal College of Surgeons is composed of about 19,000 persons, of whom nearly 18,000 are engaged in general practice, this annual meeting requests the President and Council to nominate at least two Members and (or) two Fellows in general practice to represent the interests of general practitioners in the management of College affairs.
3. That the President is hereby invited to make a statement to this meeting on the subject of the above resolution.

ANNUAL REPORT OF COUNTY MEDICAL OFFICER FOR ABERDEEN.—The report for the year 1915 of Dr. J. P. Watt, county medical officer for Aberdeen, shows a birth-rate of 23.4 per 1000 for the year, as compared with 24.1 in 1914 and an average of 24.5 for the preceding five years. The percentage of illegitimate births was 16.3, as compared with 17.0 for 1914, 18.2 for 1913, and 19.3 for 1912. The marriage-rate was 3.7 per 1000, the same as for 1914. The excess of birth- over death-rate was 9.3 per cent. The death-rate of children under 1 year was 87.8 per 1000 births, as compared with 74 per 1000 in 1914. The number of deaths from all forms of tuberculosis was 112, compared with 97 in 1914. Scarlet fever was again prevalent, though less so than in 1913, the rise being coincident with an epidemic in the city of Aberdeen, where scarlet fever reached the highest level since 1896. In the county 1913 saw the highest level of the recent wave, with an incidence of 625 cases per 100,000, as compared with 350 in 1914, and 433 in 1915. During the 23 years from 1892 to 1915, the average annual number of cases for the county was 339 per 100,000, and for the city 531 per 100,000. The case mortality was 5.2, as compared with 2.8 for 1914 and an average of 2.2 for the five preceding years, the type of the disease both in the city and in the county during the year 1915 being unusually severe.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In the 96 English and Welsh towns with populations exceeding 50,000 persons at the last Census 7691 births and 4268 deaths were registered during the week ended Saturday, Oct. 28th. The annual rate of mortality in these towns, which had declined from 13.5 to 11.8 per 1000 in the four preceding weeks, rose in the week under notice to 12.9 per 1000 of their aggregate civil population estimated at 17,312,295 persons for the year 1915. During the first four weeks of the current quarter the mean annual death-rate in these towns averaged 12.4, against 12.0 per 1000 in London. Among the several towns the death-rate last week ranged from 4.1 in Southend-on-Sea, 6.9 in East Ham, 7.0 in Hornsey, 7.2 in Acton, and 7.4 in Wimbledon, to 18.1 in Bury, 18.6 in Great Yarmouth and in Gateshead, 18.7 in Middlesbrough, and 18.8 in Bournemouth.

The 4268 deaths from all causes were 349 above the number in the previous week, and included 316 which were referred to the principal epidemic diseases, against numbers declining from 594 to 306 in the six preceding weeks. Of these 316 deaths, 221 resulted from infantile diarrhoeal diseases, 53 from diphtheria, 13 each from measles and whooping-cough, 11 from enteric fever, and 5 from scarlet fever, but not one from small-pox. The annual death-rate from these diseases was equal to 1.0, against 0.9 per 1000 in the previous week. The deaths of infants (under 2 years) from diarrhoea and enteritis, which had steadily declined from 477 to 221 in the six preceding weeks, were again 221 last week, and included 51 in London, 28 in Liverpool, 11 in Manchester, 10 in Birmingham, and 6 each in Stoke-on-Trent and Hull. The deaths referred to diphtheria, which had been 52, 45, and 40 in the three preceding weeks, rose to 53, of which 13 were registered in London, 4 each in Stoke-on-Trent and Birmingham, and 3 each in Liverpool and Middlesbrough. The fatal cases of measles, which had been 25, 21, and 17 in the three preceding weeks, further fell to 13, and included 5 in London and 2 each in Liverpool and Manchester. The deaths referred to whooping-cough, which had been 15, 23, and 10 in the three preceding weeks, rose to 13, and included 2 each in London, Stoke-on-Trent, and Manchester. The 11 deaths attributed to enteric fever were equal to the average in the three preceding weeks, and included 2 each in London, Manchester, and Hull. The fatal cases of scarlet fever, which had been 13, 9, and 7 in the three preceding weeks, further declined to 5, of which 3 occurred in London.

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had been 1037, 1074, and 1067 at the end of the three preceding weeks, rose to 1130 on Saturday last; 197 new cases were admitted during the week, against 159, 167, and 125 in the three preceding weeks. The number of cases of diphtheria, which had increased from 1262 to 1429 in the six preceding weeks, further rose to 1490; 231 new cases were admitted during the week, against 228, 194, and 188 in the three previous weeks. These hospitals also contained on Saturday last 56 cases of measles, 47 of whooping-cough, and 40 of enteric fever, but not one of small-pox. The 1053 deaths from all causes in London were 93 above the number recorded in the previous week, and corresponded to an annual rate of 12.7 per 1000. The deaths referred to diseases of the respiratory system, which had been 132 in each of the two preceding weeks, rose to 142 in the week under notice.

Of the 4268 deaths from all causes in the 96 towns, 158 resulted from violence, 362 were the subject of coroners' inquests, and 1308 occurred in public institutions. The causes of 34, or 0.8 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in London and in 13 of its 14 suburban districts, in Sheffield, Leeds, Bristol, Bradford, and in 60 other smaller towns. Of the 34 uncertified causes, 8 were registered in Liverpool, 4 in Manchester, 3 each in Birmingham and Gateshead, and 2 each in South Shields and Tynemouth.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns with an aggregate population estimated at 2,372,000 persons at the middle of this year 993 births and 587 deaths were registered during the week ended Saturday, Oct. 28th. The annual rate of mortality in these towns, which had been 15.1, 13.6, and 13.0 per 1000 in the three preceding weeks, fell to 12.9 per 1000 in the week under notice. During the first four weeks of the current quarter the mean annual death-rate averaged 13.7, against a corresponding rate of 12.4 per 1000 in the large English towns. Among the several towns the death-rate last week ranged from 3.1 in Ayr, 7.7 in Falkirk, and 8.3 in Leith, to 16.8 in Kilmarnock, 17.0 in Aberdeen, and 18.7 in Hamilton.

The 587 deaths from all causes were 2 below the number in the previous week, and included 53 which were referred to the principal epidemic diseases, against numbers declining from 92 to 53 in the three preceding weeks. Of these 53 deaths, 19 resulted from infantile diarrhoeal diseases, 18 from measles, 5 from scarlet fever, 4 each from enteric fever and diphtheria, and 3 from whooping-cough, but not one from small-pox. The death-rate from these diseases was equal to 1.2, against 1.0 per 1000 in the large English towns. The deaths of infants (under 2 years) from diarrhoea and enteritis, which had been 66, 30, and 29 in the three preceding weeks, further fell to 19, and included 9 in Glasgow, and 2 each in Edinburgh, Dundee, and Clydebank. The deaths referred to measles, which had been 8, 16, and 2 in the three preceding weeks, rose to 18, and comprised 13 in Dundee and 5 in Glasgow. The fatal cases of scarlet fever, which had been 7, 7, and 3 in the three preceding weeks, rose to 5, of which 2 occurred in Glasgow. The 4 deaths from enteric fever, which comprised 3 in Kilmarnock and 1 in Greenock, were slightly in excess of the average in recent weeks. The deaths attributed to diphtheria, which had been 5, 4, and 12 in the three preceding weeks, fell to 4, but showed no excess in any particular town. The 3 fatal cases of whooping-cough were recorded in Glasgow, Dundee, and Aberdeen respectively.

The deaths referred to diseases of the respiratory system, which had been 94, 90, and 74 in the three preceding weeks, rose to 87 in the week under notice, but were 71 below the number registered in the corresponding week of last year. The deaths from violence numbered 30, against 17 and 26 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the registration area of Dublin 179 births and 142 deaths were registered during the week ended Saturday, Oct. 28th. The annual rate of mortality, which had been 18.7, 17.7, and 17.5 per 1000 in the three preceding weeks, rose to 18.7 in the week under notice, against 12.7 and 11.8 per 1000 in London and Glasgow respectively.

The 142 deaths from all causes included 35 of infants under 1 year and 40 of persons aged 65 years and upwards. Eleven deaths (of infants under 2 years) were referred to diarrhoeal diseases, and 1 each to enteric fever, scarlet fever, and whooping-cough. The causes of 5 deaths were uncertified, and those of 4 others were the subject of coroners' inquests, while 48, or 34 per cent., of the total deaths occurred in public institutions.

During the same period 167 births and 118 deaths were registered in the city of Belfast. The deaths corresponded to an annual rate of 15.8, or 2.7 per 1000 above that recorded in the previous week, and included 24 of infants under 1 year and 21 of persons aged 65 years and upwards. Seven deaths were referred to infantile diarrhoea and 2 each to scarlet fever and whooping-cough. The causes of 2 deaths were uncertified, and those of 4 others were the subject of coroners' inquests, while 25 of the total deaths occurred in public institutions.

VITAL STATISTICS OF LONDON DURING SEPTEMBER, 1916.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases, it appears that the number of persons reported to be suffering from one or other of the 10 diseases specified in the table was equal to an annual rate of 4.9 per 1000 of the civil population, estimated at 4,310,030 persons in the middle of the year; in the three preceding months the rates had been 4.8, 4.9, and 4.0 per 1000 respectively. The lowest rates for September were recorded in Kensington, Hammer-smith, the City of Westminster, St. Marylebone, Finsbury, and Lewisham; and the highest rates in the City of London, Shoreditch, Bethnal Green, Stepney, Southwark, and Deptford. The prevalence of scarlet fever showed a considerable increase over that recorded in the preceding month; among the several boroughs this disease was proportionally most prevalent in Paddington, the City of London, Bethnal Green, Stepney, and Poplar. The Metropolitan Asylums Hospitals contained 1007 scarlet fever patients at the end of September, against 1256, 1201, and 991 at the end of the three preceding months; the weekly admissions averaged 143, against 163 and 120 in the two preceding months. Diphtheria also was much more prevalent in September than it had been in August; the greatest proportional prevalence of this disease was recorded in Holborn, the City of London, Shoreditch, Bethnal Green, Stepney, and Southwark. There were 1287 diphtheria patients under treatment in the Metropolitan Asylums Hospitals at the end of September, against 1280 and 1236 at the end of the two preceding months; the weekly admissions averaged 167, against 153 and 135 at the end of the two preceding months. The prevalence of enteric fever showed a slight rise; of the 43 cases notified during

* Including membranous croup.

the four weeks ending Sept. 30th, 5 belonged to Camberwell, 4 each to Islington, Poplar, and Battersea, and 3 each to the City of Westminster, Hampstead, and St. Pancras. The Metropolitan Asylums Hospitals contained 35 enteric fever patients at the end of September, against 44, 40, and 35 at the end of the three preceding months; the weekly admissions averaged 7, against 5 in each of the two preceding months. Erysipelas was proportionately most prevalent in the City of Westminster, Shoreditch, Bethnal Green, Stepney, Southwark, and Deptford. The 17 cases of puerperal fever notified during the month included 3 in Southwark, and 2 each in Hackney, Battersea, Wandsworth, and Woolwich. The 16 cases of cerebro-spinal meningitis included 3 in Lambeth and 2 each in Poplar, Bermondsey, and Greenwich; and of the 45 cases of poliomyelitis, 6 belonged to Bermondsey, 5 to Poplar, 5 to Lambeth, 5 to Camberwell, 3 to Islington, and 3 to Southwark.

The mortality statistics in the table relate to the deaths of persons actually belonging to the several metropolitan boroughs, the deaths occurring in institutions having been distributed among the several boroughs in which the deceased persons had previously resided. During the four weeks ending Sept. 30th the deaths of 3980 London residents were registered, equal to an annual rate of 12.0 per 1000, against 11.5, 10.7, and 10.6 per 1000 in the three preceding months. The death-rates for September ranged from 6.7 in the City of London, 7.8 in Hampstead, 9.5 in Paddington, 10.1 in Hammersmith, and 10.3 in Stoke Newington and in Woolwich, to 13.5 in Deptford, 13.6 in Lambeth, 13.8 in Shoreditch, 13.9 in Finsbury, 14.1 in Chelsea, 16.0 in Bermondsey, and 16.6 in Poplar. The 3980 deaths from all causes included 480 which were referred to the principal infectious diseases; of these, 43 resulted from measles, 3 from scarlet fever, 26 from diphtheria, 16 from whooping-cough, 6 from enteric fever, and 386 from diarrhoea and enteritis among children under 2 years of age. No death from any of these diseases was recorded during September in the City of London or in Hampstead; among the other boroughs they caused the lowest death-rates in Kensington, Hammersmith, the

City of Westminster, St. Marylebone, and Holborn; and the highest rates in Shoreditch, Bethnal Green, Poplar, Southwark, and Deptford. The 43 deaths from measles were slightly less than the corrected average number in the corresponding period of the five preceding years; of these 43 deaths, 7 belonged to Southwark, 6 to St. Pancras, 6 to Lambeth, 4 to Stepney, 4 to Bermondsey, 3 to Poplar, and 3 to Camberwell. The 3 fatal cases of scarlet fever were 12 below the corrected average number; 2 belonged to Shoreditch and 1 to Stepney. The 26 deaths from diphtheria were 19 below the corrected average number, and included 4 in Camberwell, 3 in Stepney, and 2 each in Islington, Bethnal Green, Southwark, Lambeth, and Lewisham. The 16 fatal cases of whooping-cough were 34 less than the corrected average number; of these 16 deaths 3 belonged to Woolwich and 2 each to Fulham and Southwark. The 6 deaths from enteric fever were 8 below the corrected average, and belonged respectively to St. Marylebone, Shoreditch, Bethnal Green, Stepney, Poplar, and Bermondsey. The deaths from diarrhoea and enteritis among children under 2 years of age were 455 below the corrected average number; the greatest proportional mortality from this cause was recorded in Shoreditch, Bethnal Green, Poplar, Southwark, and Deptford. In conclusion, it may be stated that the aggregate mortality in London during September from these principal infectious diseases was 49.5 per cent. below the average.

MEMORIAL TO SIR HENRY SWANZY.—The Archbishop of Dublin unveiled recently a memorial which has been erected to Sir Henry Swanzy in the Royal Victoria Eye and Ear Hospital, Dublin. Shortly after Sir Henry Swanzy's death a public appeal for subscriptions to a memorial in his memory was issued and nearly £1500 were received. This sum has been devoted to the completion of a wing of the Royal Victoria Hospital, in the foundation of which Swanzy had been active. The personal memorial which was unveiled last week is a bronze bas-relief portrait by Mr. Oliver Sheppard, R.H.A.

Correspondence.

"Audi alteram partem."

THE DIFFERENTIATION OF HEART MURMURS IN SOLDIERS.

To the Editor of THE LANCET.

SIR,—Amongst the many problems in connexion with war illness presented for solution, few are more interesting and more difficult than the distinction between organic valvular defects and their counterpart, or mimicry, occurring in the course of functional heart derangement. The importance of a correct diagnosis can scarcely be over-estimated, and the difficulties the problem presents may be gauged by the fact that a large number of cases have reached the hospitals in this country with the diagnosis of V.D.H. (valvular disease of the heart), which long and careful observation and suitable treatment have proved to be functional. In the majority of these cases the diagnosis was presumably based upon the existence of a murmur, though no doubt other signs and symptoms were also taken into consideration.

The cause and detection of functional heart murmurs has interested me for many years, and my connexion with the Northumberland War Hospital has afforded me considerable fresh opportunity of investigating the subject as well as the nature of the so-called "soldier's heart" generally. But my object in writing this letter is to call attention to a method by which I believe functional murmurs can, as a rule, be distinguished from organic. I may say that in my experience a systolic bruit can be detected in the great majority of cases of functional derangement of the heart arising in some way out of war conditions, whether from strain, shell-shock, or other nervous causes. It is true these murmurs are not always present; at times they stop and remain absent for hours; they may be audible when lying and not when standing, or *vice versa*; they may diminish even to vanishing-point under examination; but frequent examinations will nearly always lead to their detection, and they are usually best heard towards the right of the apex, and especially when the patient is lying on his left side. They are not well conducted beyond the apex, and often cease when the patient draws and holds a long breath. The chief point, however, to which I wish to draw attention is the fact, which I regard as almost conclusive, that the functional apical murmur will at once become inaudible when the fingers of the observer holding the bell-piece of the binaural stethoscope press in the ribs upon the heart as the patient lies on his left side. It is well when examining the case to stand on the right side of the bed and stoop over the patient, and in this way the fingers of both hands can be employed to press in the ribs and interspace auscultated upon the heart; or the observer may be on the left side of the patient and an assistant directed to make the necessary pressure. In the case of organic murmurs—e.g., those of mitral regurgitation—the firmest pressure fails to render the bruit inaudible, and may intensify it.

I may mention incidentally that I have noticed whilst investigating heart murmurs in this way that pressure considerably modifies the presystolic bruit of mitral stenosis, for as the chest wall is being pressed in upon the apex the murmur becomes shortened and loses some of its rough character. It would seem that firm pressure renders inaudible sounds which are really due to chest-wall vibrations, and are therefore exocardiic in origin.

I am, Sir, yours faithfully,

Newcastle-on-Tyne, Oct. 24th, 1916. DAVID DRUMMOND.

THE MANUFACTURE OF SALVARSAN PRODUCTS IN ENGLAND.

To the Editor of THE LANCET.

SIR,—Major Ernest Lane has drawn renewed attention in THE LANCET of Sept. 30th to his unfortunate experiences with kharsivan. We feel that it would be unfair to the firm of chemists which was so enterprising as to place this substance at the disposal of British medical men so soon after the beginning of the war if we were not to state our own experience, which has been very much more favourable than his.

We have used about 1400 doses of kharsivan and neo-kharsivan (nearly all the former), the injections having been given by one of us or under our supervision. In military cases we have followed the new Army regulations for the treatment of syphilis, and in civil and private practice we have usually given the full dose of 0.6 gramme to adult males and females alike. Our experience has been the same. We have seen no symptom which could possibly be considered as being due to arsenical poisoning, no rashes, no violent reactions, and, in short, nothing which could give either of us a single moment's uneasiness as to any of our patients. In most cases there are no symptoms of any sort, but in early syphilis there is usually a slight temperature reaction, rarely exceeding 100° F., but this almost always subsides in a few hours. There is often some slight gastric disturbance; anything more than this can usually be traced to a surreptitious meal before or after the injection. Often there is a sharp movement of the bowels, rarely diarrhoea. No patient has been kept in bed for more than one night owing to the severity of the symptoms.

Most of our patients have been young and otherwise healthy men, but in the civil practice of King's College Hospital and in private there have been numerous injections in older men and in females of all ages. One of us injected a man 70 years of age, who suffered from severe cystitis due to B.coli, without any unpleasant results. We make a routine examination of the urine in all cases, and regard even a slight trace of albumin, if probably of renal origin, as a contraindication. So far we have met with no other. In all cases the patients are prepared as for an operation, being given an aperient the previous night and kept in bed for about four hours without food before the injection. They stay in bed for the rest of the day, and are only given light food. We use water that has been distilled in the laboratories of the hospital under the supervision of one of us and autoclaved immediately afterwards. We take care that the vessel containing it is not opened, even momentarily, after sterilisation until it is required for use. We dissolve the drug in water which is nearly cold, and add about five or six drops of 15 per cent. caustic soda beyond the point required for complete re-solution of the precipitate. We never use a solution which has been prepared for more than half an hour, and prefer to use it as soon as it has been prepared.

We are, Sir, yours faithfully,

W. D'ESTE EMERY,
Captain, R.A.M.C. (T.).
JOHN EVERIDGE,
Captain, R.A.M.C. (T.).

Harley-street, W., Oct. 31st, 1916.

ENTEROCOCCUS IN THE URINE OF CONVALESCENT SOLDIERS.

To the Editor of THE LANCET.

SIR,—In an important paper in your issue of Oct. 7th attention is called by Major T. Houston and Captain J. M. McCloy to the importance of the enterococcus in "trench fever" and allied conditions. Certain observations made by us in the routine examination of the urine of soldiers convalescent from enteric fever, paratyphoid fever, and dysentery led us to the conclusion that military service abroad and perhaps the occurrence of lesions in the intestine were often followed by the invasion of the system by enterococci and by their excretion in the urine. In fact, urinary "enterococcic carriers" are very commonly met with among soldiers at command depôts and convalescent camps. Many of these "carriers" suffered from vague articular and myalgic pains, others had no symptoms whatever.

We find on consulting our records that in one series of 162 specimens examined 22 were found to contain enterococci. A number of these strains were tested as to their fermentative reactions, and we found that there was considerable variation among the individual strains, some having the characters of what we usually term in this country streptococcus faecalis, and as such generally fermenting mannite, others fermented glucose, lactose, and saccharose, but not mannite, whilst some had no action on any sugar, and in this respect corresponded with the description given by French bacteriologists, such as Macé, to the enterococcus. French writers¹ have recently shown that frequently the

¹ Sartory, Lasseur et Spillmann: Diplocoque dans le Sang des Suspects de Typhoïde. *Compt. R. de la Soc. de Biolog.*, vol. lxxviii., p. 257 (1915), and Burges, Lancellin et Joly in *Compt. R. de la Soc. de Biolog.*, vol. lxxviii., p. 632. Also Lebrun et Portier, *ibidem*, p. 440.

enterococcus gives rise to a condition clinically resembling enteric fever, and that it is often associated with the *B. typhosus* in other cases.

It is evident, therefore, that the enterococcus plays an important rôle in infective processes, and the work of Major Houston and Captain McCloy would seem to show that many cases of "trench fever" are due to its activity. I think most observers will agree with their conclusion, which is very cautiously stated in the following words: "Our experience with the enterococcus appears to show that when the organism is found in urine it is frequently an infecting agent." In rheumatic conditions it is very common to get enterococci in the urine, and vaccines prepared from cultures are often very efficacious in treatment. Our own observations tend to show that subsequent to an acute infection enterococci continue to be found in the urine. There is evidently a sort of subinfection which, under certain conditions, may become acute.

We are, Sir, yours faithfully,

GEORGINA DARLING, M.B., D.P.H.,
W. JAMES WILSON, M.D., D.Sc.,
Captain, R.A.M.C. (T.F.); Specialist Sanitary
Officer, Belfast District.

Hygiene and Public Health Laboratory, Queen's
University, Belfast, Oct. 19th, 1916.

SOLDIERS AND VENEREAL DISEASES.

To the Editor of THE LANCET.

SIR,—During the past two years the Liverpool Medical Institution has distributed over 160,000 copies of pamphlets especially written in plain non-technical language for soldiers, warning them of the dangers and disabilities incurred by contracting these avoidable diseases. The Army authorities in Egypt have reprinted the tract for their own use. We desire to enlist your support by the insertion of this letter, and invite inquiries for specimen copies from commanding officers, medical officers, chaplains, social workers, and others interested in our soldiers, addressed to the Librarian, the Medical Institution, Liverpool.

I am, Sir, yours faithfully,

CHARLES J. MACALISTER,
President.

Liverpool, Oct. 31st, 1916.

THE ETHICAL STANDARDS OF PANEL PRACTICE.

To the Editor of THE LANCET.

SIR,—In Dr. Mitchell Bruce's address to students at the opening of the winter session the following passage occurs (*vide* THE LANCET, Oct. 21st):—

It is in this way surely that you have been brought to Charing Cross Hospital to-day—not, I am sure, for purely commercial ends, which it is to be feared have been promoted by the panel.

I presume the concluding word refers to National Health Insurance practice, and it strongly suggests, if it does not actually accuse, panel practitioners of lacking in the spirit of medicine which ought to inspire them—that they are tempted by the conditions of panel practice to dishonour their calling. This is an offensive remark, uttered *ex cathedra*, and I trust that the young students who will later on join a panel will not accept the view that panel practice does not claim as many conscientious doctors in its ranks as any other form of medical practice. The integrity of Dr. Bruce's excellent address is marred by this unfortunate reference, which I am sure is quite undeserved.

I am, Sir, yours faithfully,

Kensington, W., Oct. 24th, 1916.

O. ECCLES.

SPINAL ANÆSTHESIA IN ACUTE ABDOMEN.

To the Editor of THE LANCET.

SIR,—The advocates of the above method make no mention of the minor drawbacks, which probably appeal to the anæsthetist more than to the surgeon. Supposing one is dealing with a case in which there are acute suppuration and general peritonitis, surely the mere act of turning the patient on to his side cannot improve the condition; and if there is a large localised abscess on the verge of rupture before adhesions have been firmly developed, then this moving about might possibly tend to break them down. Another

objection is that though the superficial tissues are anæsthetised with ethyl chloride or hypodermic injection of novocaine there is still some pain caused when the needle is pushed through the deep tissues into the spinal canal, which gives rise to a certain amount of shock. There is always the drawback to a nervous patient that he is conscious of the progress of the operation, and when the peritoneum or mesentery is handled to any extent there is considerable discomfort. Lastly, anyone who has any experience of spinal anæsthesia is aware that a small proportion of cases show signs of collapse from the anæsthetic *per se*.

The most satisfactory anæsthesia in acute abdomen, in my experience, is obtained by giving the patient a hypodermic of morphine and atropine followed by gas and oxygen administered with some such apparatus as the Gwathmey, with or without the local injection of novocaine. If the latter is used then there ought to be no difficulty about getting complete relaxation, but even if it is not used the result is so good, in that there is almost complete freedom from shock, that the temporary inconvenience to the surgeon ought to be well compensated for by the advantage gained by the patient. The addition of a small quantity of ether or mixture makes very little difference as regards after-effects to the patient and helps the relaxation.

I am, Sir, yours faithfully,

HUGH R. PHILLIPS, M.D. Edin.,
Senior Anæsthetist, Italian Hospital; Anæsthetist to the King
George Hospital, Royal Flying Corps, and Endsleigh Palace
Hospital for Officers.

Dawson-place, W., Oct. 21st, 1916.

FALLOPIAN TUBE FOUND IN FEMORAL HERNIA.

To the Editor of THE LANCET.

SIR,—The following notes may be of interest in connexion with similar cases reported in THE LANCET of Oct. 21st and 28th:—

A woman while doing housework one afternoon was seized with a sudden severe pain in the lower part of the abdomen. She was about five months pregnant at the time, and thinking she was threatened with a miscarriage she sent for the midwife. The nurse gave her an enema, the bowels acted freely, and the pain lessened somewhat. She became worse later in the evening and I saw her about midnight. Her temperature was normal, pulse 102. Vaginal examination showed no signs of labour. The bowels had acted and she had not vomited, but she looked very distressed, and there was a slight rigidity in the lower part of the abdomen. She was a corpulent woman; she was not aware of the existence of a hernia, and it was only after careful examination that a small swelling no bigger than a walnut was found embedded, so to speak, in the fat of the right groin. It was dull on percussion, irreducible, and had no impulse on coughing; it was thought to be a strangulated femoral hernia containing a small piece of omentum. On opening the sac about a tea-spoonful of turbid serum escaped. The only structure found in the sac was the fimbriated extremity of the Fallopian tube; it was intensely injected and of a dark purple colour. Doubts were entertained as to the vitality, so I excised it and closed up the femoral ring. She carried the foetus to full term, and was delivered of a healthy male child.

The points of interest are the presence of the Fallopian tube in a femoral hernia at the fifth month of pregnancy; the difficulty of exact diagnosis, the absence of vomiting, the movement of the bowels, the dull percussion note suggested omentum. The excision of the tube has apparently not interfered with subsequent conception, for since the operation, five years ago, she has given birth to two full-term children.—I am, Sir, yours faithfully,

J. F. DEVANE, M.D., F.R.C.S. Irel.,
Hon. Surgeon, Limerick County Infirmary, and
St. John's Hospital, Limerick.

Oct. 30th, 1916.

SKIAGRAMS OF GAS GANGRENE.

To the Editor of THE LANCET.

SIR,—In the report of my paper on Gas Gangrene in your issue of Oct. 28th (p. 754) an error appears. The French worker who had great experience with cases showing a fine striation believed that the *vibrio septique* was always found where that X ray appearance was seen. He recognised there were other appearances due to other organisms which were equally capable of giving rise to gas gangrene.

I am, Sir, yours faithfully,

Weymouth-street, W., Oct. 29th, 1916.

AGNES SAVILL.

The War.

THE CASUALTY LIST.

THE following names of medical officers appear among the casualties announced since our last issue :—

Killed.

Capt. A. T. Logan, R.A.M.C., attached Grenadier Guards, received his medical education at the University of Glasgow, where he gained the Dr. Gibson bursary, and qualified in April, 1915. He obtained his commission in the R.A.M.C. and went to the front forthwith, and has been mentioned in despatches.

Lieut. W. C. E. Bower, R.A.M.C., attached Newfoundland Regiment, received his medical education at University College, London, and qualified in 1900. After filling appointments at the Carlisle Dispensary and at the Prestwich Asylum, Manchester, he joined the West African Medical Service, and received his commission in the R.A.M.C. in the early part of last September.

Died of Wounds.

Capt. C. M. Nicol, R.A.M.C., received his medical education at the University of Glasgow and qualified M.B., Ch.B. in 1909. He thereupon joined the R.A.M.C. and was gazetted Captain in 1912. At the outbreak of war he was doing duty in Egypt, and later proceeded to France. Captain Nicol has been mentioned in despatches.

Died.

Lieut.-Col. E. Hudson, I.M.S., was a student at University College, London, and qualified in 1882. He obtained his commission in the I.M.S. in 1886, and had held the appointment of superintendent of the Central Prison, Allahabad. He served in the Chin-Lushai Expedition in 1889-90, and was mentioned in despatches. He died at Allahabad.

Wounded.

Capt. M. J. Rees, R.A.M.C.

Capt. F. Hitchcock, New Zealand Medical Corps.

Capt. H. R. Mustard, Canadian Army Medical Corps.

THE VICTORIA CROSS.

The King has conferred this distinction upon the following members of the medical profession :—

Capt. William Barnsley Allen, M.C., R.A.M.C.

For most conspicuous bravery and devotion to duty. When gun detachments were unloading H.E. ammunition from wagons which had just come up, the enemy suddenly began to shell the battery position. The first shell fell on one of the limbers, exploded the ammunition and caused several casualties. Captain Allen saw the occurrence and at once, with utter disregard of danger, ran straight across the open, under heavy shell-fire, commenced dressing the wounded, and undoubtedly by his promptness saved many of them from bleeding to death. He was himself hit four times during the first hour by pieces of shells, one of which fractured two of his ribs, but he never even mentioned this at the time, and coolly went on with his work till the last man was dressed and safely removed. He then went over to another battery and tended a wounded officer. It was only when this was done that he returned to his dug-out and reported his own injury.

Capt. Allen is the only son of Mr. P. Allen, of Scarborough, and was educated at St. Cuthbert's College, Workson, and at Sheffield University, where he won a gold medal in 1913, and qualified M.B., Ch.B. in 1914. After holding a short appointment at Sheffield Royal Hospital he joined the R.A.M.C. in the August following, and was awarded the Military Cross last August.

Capt. Noel Godfrey Chavasse, M.C., R.A.M.C.

For most conspicuous bravery and devotion to duty. During an attack he tended the wounded in the open all day, under heavy fire, frequently in view of the enemy. During the ensuing night he searched for wounded on the ground in front of the enemy's lines for four hours. Next day he took one stretcher-bearer to the advanced trenches, and under heavy shell-fire carried an urgent case for 500 yards into safety, being wounded in the side by a shell splinter during the journey. The same night he took up a party of 20 volunteers, rescued three wounded men from a shell-hole 25 yards from the enemy's trench, buried the bodies of two officers, and collected many identity discs, although fired on by bombs and machine-guns. Altogether he saved the lives of some 20 badly wounded men, besides the ordinary cases which passed through his hands. His courage and self-sacrifice were beyond praise.

Capt. Chavasse is the younger of the twin sons of the Lord Bishop of Liverpool, and was educated at Liverpool College and at Oxford, and qualified in 1912. He was a keen university athlete, as was also his twin brother, and all four sons of the Bishop are in the Army. Capt. Chavasse, previously to the war, held an appointment at the Liverpool Southern Hospital, and on mobilisation he joined the R.A.M.C. and went abroad. He took part in the engagement at Hooge, in connexion with which he was awarded the Military Cross for conspicuous bravery.

MENTIONED IN DESPATCHES.

In a despatch from General Sir Reginald Wingate, Sirdar and Governor-General of the Soudan, dealing with the military operations in that country, the names of the following R.A.M.C. officers are mentioned :—

Lieut.-Col. F. F. Carroll, Major R. G. Anderson, Major W. Byam, Capt. R. G. Archibald, Capt. D. S. Buist, Capt. C. Cassidy, Capt. A. G. Cummins, and Capt. G. Gibbon.

Dr. A. J. Chalmers, of the Wellcome Research Laboratories, Khartoum, and Dr. E. S. Crispin, of the Medical Department of the Soudan Government, are also mentioned.

In a despatch dealing with the Navy the names of Staff-Surgeon E. Cameron, R.N., and Surgeon F. G. Hitch, R.N., are mentioned.

DEATHS AMONG THE SONS OF MEDICAL MEN.

The following sons of medical men must be added to our lists of those who have fallen during the war :—

Second Lieut. E. H. Montgomery, Royal Field Artillery, son of Dr. E. H. Montgomery, of Mallow, Co. Cork, Ireland.

Second Lieut. R. A. S. Wilson, Seaforth Highlanders, elder son of Dr. A. S. Wilson, of St. Leonards-on Sea.

Second Lieut. C. R. P. Corbin, Worcestershire Regiment, elder son of the late Dr. E. R. St. Clair Corbin, of Beckenham, Kent.

Sergt. R. J. Watt, South African Infantry, only son of the late Dr. T. M. Watt, of Hovingham, Yorkshire.

Capt. V. H. Clay, Wilts Regiment, younger son of Dr. C. Clay, of Fovant, near Salisbury.

Second Lieut. C. J. Girling, Hampshire Regiment, elder son of Dr. C. J. Girling, of Cranborne, Salisbury.

SURGEONS FOR THE FRENCH WOUNDED.

Mr. D. H. Illingworth, Directeur-Général, London Committee of the French Red Cross, 9, Knightsbridge, S.W., writes to us as follows :—

Some twenty-five British-staffed hospitals in France are working for the French wounded. In one of these, an important 300-bed hospital in the war zone, the honorary post of surgeon-in-charge will shortly become vacant, and it is hoped to find a British surgeon who is able to undertake this responsible work. There are other vacancies, both honorary and paid, for assistant operating surgeons and house surgeons, and I shall be very pleased to furnish full details of this excellent service to surgeons who are not able to serve with the British Forces.

The supply of medical men is being very seriously drawn upon in every direction, but we hope that the Croix Rouge Française will obtain promptly the necessary assistance to their splendid work.

MEDICAL CERTIFICATES FOR MUNITION WORKERS.

The Minister of Munitions has recently called the attention of the Council of the British Medical Association to the difficulty experienced by firms engaged on munitions work in dealing with application from workmen for leaving certificates, owing to the alleged fact that medical certificates recommending a change of employment have sometimes been issued by practitioners without sufficient consideration. We have no details of the grounds on which these certificates were issued, but it is evidently to the advantage of the health of the munition worker, who now forms no inconsiderable proportion of the total civilian population of the country, to have the supervision of his or her own medical adviser, who should state his opinion without fear or favour. And there are two reasons why the practitioner should keep an open mind and not recommend a change of employment without careful consideration of the special circumstances. In the first place, the conditions in controlled works as regards hours of employment, intervals of relaxation, provision of cheap and adequate meals, are such that a change may readily turn out to be a disadvantage to the worker. And in the second place, especially where the labour of women and young people of either sex is concerned, the workers' health has been made the direct care of the Health of Munition Workers Committee, and in many instances already the advice of nurse or of medical officer is available in the factory. Some collaboration between these and the worker's home doctor is evidently desirable, and the added knowledge might save the issue of a certificate by the latter based on insufficient or misleading data.

OBITUARY OF THE WAR.

ALFRED HUGH BENSON, M.R.C.S. ENG., L.S.A.,
MAJOR, ROYAL ARMY MEDICAL CORPS.

Major A. H. Benson, who died on active service on Sept. 24th, was only surviving son of the late Richard Benson and of Mrs. Benson, of 74, Philbeach-gardens, S.W. He was educated at St. Peter's College, Radley, and Caius College, Cambridge, qualifying in 1887. He served through the South African campaign, was wounded at Johannesburg while attached to the Gordon Highlanders, and received the Queen's medal with five clasps and the King's medal with two clasps. He settled in Cleobury Mortimer, where he built up a large practice in and around the town. On the outbreak of war he volunteered for service and served for eight months with the Expeditionary Force, returning to England for a home appointment. He died

when on military service at Scarborough and was buried in Seamer churchyard.

Major Benson is described as a staunch colleague and as a commanding officer who was ever watchful of the interests and comfort of his men. He leaves a widow, a daughter, and a son who is serving with Lord Strathcona's Horse at the front.

THOMAS LEWIS INGRAM, M.A. CANTAB., M.R.C.S. ENG.,
D.S.O., M.C.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain T. L. Ingram, D.S.O., who was killed in action on or about Sept. 16th, at the age of 41, was the eldest son of Thomas Lewis Ingram, of The Priory, Wimbledon Common. He was educated at Monkton Combe School and Trinity College, Cambridge, qualifying in 1903, and then held house appointments at Westminster and Poplar Hospitals. He served as a trooper in the Imperial Yeomanry during the

South African War, gaining the Queen's medal with three clasps. He was in practice at Welford, near Rugby, when the present war broke out; he applied at once for a commission in the Royal Army Medical Corps and in November, 1914, was attached as medical officer to the King's Shropshire Light Infantry, with which regiment he served till his death.

Early in 1915 Captain Ingram was mentioned in despatches; on Sept. 6th, 1915, he was

awarded the Military Cross "for conspicuous devotion to duty and energy at Hooge"; and on May 31st, 1916, he was awarded the D.S.O. "for conspicuous gallantry and devotion to duty. He collected and attended to the wounded under very heavy fire and set a splendid example. Since the commencement of the war he has been conspicuous on all occasions for his personal bravery." His colonel, in writing of him as the bravest man he had ever met, added: "He was loved by every man in the regiment."

Captain Ingram married in 1909 Lilian, eldest daughter of the late Lieutenant-Colonel Donnithorne, Royal Scots Greys, and leaves two children.

WILLIAM FRANCIS MACALEVEY, M.R.C.S. ENG.,
CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain W. F. MacAlevey, who was killed in action on Sept. 27th, at the age of 26, was the elder son of Mr. W. C. MacAlevey, of Leicester. He was educated at Stoneygate Preparatory School, Leicester, and at Mount St. Mary's College, Chesterfield, where he was captain of the school, and at St. Mary's Hospital Medical School, where he gained a science scholarship. He obtained the diplomas of the Conjoint Board in 1915, and had intended to take the Final M.B. Lond. after the war. In February, 1915, he took a temporary commission in the R.A.M.C. and went to the front with a field ambulance, to which he became transport officer and later adjutant. On the morning of his death

a squad of stretcher-bearers bringing in a wounded man reported that one of their number had fallen by the way, and was, they thought, killed. Captain MacAlevey went out at once alone to look for the missing man and was killed instantly by a shell.

At hospital Captain MacAlevey was an athlete, being captain of the Association football team and a member of the Rugby fifteen. His senior officer describes him as a man eminently suited for the double profession of doctor and soldier, and as untiring in his devotion to duty. As transport officer "he used to care for the horses as if they were sick men."

MARTIN WILLIAM LOY, M.R.C.S. ENG.,

LIEUTENANT, ROYAL ARMY MEDICAL CORPS.

Lieutenant M. W. Loy, who was killed in action on August 28th, 1916, at the age of 43, was fifth and youngest son of the late S. H. Loy, of Keld Head, Pickering. He took his medical course at the London Hospital, obtaining the Conjoint Board qualification in 1894, and then held in succession the appointments of clinical assistant, house surgeon, and receiving-room officer at the hospital. He then entered practice at Thornton-le-Dale, Yorkshire, in partnership with Dr. R. A. Scott, removing in 1902 to Gillingham, Kent. Early in 1916 he obtained a commission in the Royal Army Medical Corps, and went to France with a casualty clearing station, being afterwards attached to the Cheshire Regiment until the time of his death. Lieutenant Loy married in 1909 Edith Christine, elder daughter of the late Lieutenant-Colonel H. D. Bicknell, of Lymington, Hants.

It is reported that Surgeon-Probationer A. L. Strachan, R.N.V.R., has lost his life in the mine-sweeper *Genista*, torpedoed on Oct. 23rd.

PROVISION OF FOOD AND COMFORTS FOR NAVAL PRISONERS.

Although a Central Prisoners of War Committee of the British Red Cross Society and the Order of St. John of Jerusalem has been appointed, no change has been made in the work of the Ladies' Emergency Committee of the Navy League and the Royal Naval Division Comforts Funds, which will continue to act in regard to the Royal Navy and the Royal Naval Division in the same capacity as regimental associations in respect of the Army. The address of the Ladies' Emergency Committee of the Navy League is 47, Grosvenor-square, W., and of the Royal Naval Division Comforts Fund, Denison House, Westminster, S.W.

A MOTOR X RAY OUTFIT.

We give an illustration of one of the five X ray motor-wagons recently presented by the Scottish branch of the British Red Cross Society for service with the British Army in the field. The wagon has been made by the Albion Motor Car Company, Limited, Glasgow; the chassis is of the 32 h.p. Albion 3-ton type, and the body has been constructed to meet

Motor Wagon with X Ray Outfit.

the special requirements. The door half open in the centre of the body shows the accumulators, which are supplied with current from a dynamo mounted on the chassis under the driver's seat; the dynamo is driven by means of a clutch arrangement from the cardan shaft of the vehicle. The X ray tube is fixed to a carriage on rails for operating purposes. The negative-holder is above the table, as well as a small screen for protecting the legs of the operator travelling on a single rail to follow the X ray tube. The two cable-drums, one attached underneath the rear portion of the body, and the other seen lying on the ground, are to enable the X ray operating table to be taken some distance away from the vehicle should circumstances make this necessary. The canopy shown extended at the back of the wagon is collapsible and the whole apparatus can be stored inside the vehicle for transporting from place to place.

THE FEDERATED MALAY STATES HOSPITAL AT KIMPTON.

The military hospital maintained at Blackmore End, Kimpton (Herts), by public subscriptions from the Federated Malay States for sick and wounded soldiers has been enlarged by the addition of a new ward containing 44 beds. This brings the total number of beds available to over 200. A large recreation room is in course of construction. The hospital is under the charge of Captain G. D. Freer, R.A.M.C. (T.), formerly Principal Medical Officer, Selangor, F.M.S. Miss Willis, late of the Royal Free Hospital, is matron.

THE ARMENIAN REFUGEES (LORD MAYOR'S) FUND.

The good work which this Fund is doing is well illustrated by the fact that the recent retreat of 25,000 Armenians through dangerous mountain passes, under the guidance of Mr. George F. Gracey, an American Missionary, was successfully accomplished owing in a large measure to the money provided by the Lord Mayor's Fund. The Fund, which also assists Assyrian refugees, is in urgent need of financial support and is deserving of every help. Donations may be sent to either 96, Victoria-street, S.W., or to the Mansion House, London.

THE WAR OFFICE AND THE DUBLIN HOSPITALS.

Since early in the war the general hospitals of Dublin, as of course those in other centres, have acceded to the request of the War Office to treat wounded soldiers in as large numbers as they can accommodate. All the hospitals have set apart wards for the purpose and have placed their resources unreservedly at the disposal of the military authorities. Payment has been made to the hospitals at a rate of from 2s. to 4s. a day for soldiers, the usual rate being 3s. a day, medical and surgical attendance being given free by the visiting staffs in all cases. Early in the war the payments made by the War Office were probably sufficient to pay for the maintenance of the soldier patients, but with the present high prices they have been inadequate, and the reception of wounded soldiers has imposed a tax on the finances of the hospitals. In these circumstances the hospital authorities have received with mixed feelings a memorandum from the War Office, stating that it has come to the knowledge of the War Office that in some cases the payments made to the hospitals more than covered the actual outlay on food, heating, surgical necessities, &c.; that in

future no payment will be made in excess of what is spent on such objects as those enumerated; that no charge is to be made for medical or nursing services, or for rent of premises. "It is impossible," says our Dublin correspondent, "to find any justification for the demand that medical and nursing services are to be given gratuitously, although as a matter of grace they have been so given. The lack of tact shown by the War Office is not unlikely to make the hospitals insist that the entire expense of maintaining soldiers shall be borne by the authorities."

WOUNDED ALLIES RELIEF COMMITTEE.—The address of the Wounded Allies Relief Committee is now changed from Sardinia House, Kingsway, W.C., to 8, Grosvenor-gardens, S.W., the new premises having been lent to the committee by Lord Ilchester.

MALARIA IN CALCUTTA.—At a recent meeting the Health Special Committee of the Calcutta Corporation considered the health officer's proposal to reorganise the mosquito brigades and to undertake systematic anti-malaria measures in selected areas. A number of mosquito brigades are appointed for a period of about six months every year. They usually work from October to March in the suburban wards. The proposed expenditure under the new scheme is Rs.3,214 as against Rs.4,749. The committee temporarily sanctioned the scheme, and asked the medical officer to get out a scheme for concentrating the work of the mosquito brigades on particular localities. It was also decided to ask Dr. C. A. Bentley, Sanitary Commissioner, Bengal, to help the committee in the matter.

Medical News.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—At the recent dental examinations just concluded the following candidates passed the First Dental Examination:—

Alfred McCamley and James Rowan Sherrard.

The following passed in the subject of Chemistry and Physics:—

Herbert Daniel Howard.

At the same diet the following candidates passed the Final Examination and were granted the diploma L.D.S. R.C.S.Edin.:—

Bertine Loring Kelly, United States; Johannes Augustus Stegmann, South Africa; John McLean Foreman, Kirkcaldy; Roelof George du Toit, South Africa; John Russell Watson, Edinburgh; and James Henry Brown, Edinburgh; and George Laing passed in the subject of Medicine and Surgery.

ROYAL MEDICAL BENEVOLENT FUND.—At the last meeting of the committee, held on Oct. 10th, 31 cases were considered and £300 voted to 30 of the applicants. The following is a summary of some of the cases relieved:—

M.R.C.S. Eng., aged 71, a widower, who practised at Great Torrington and West Africa, and latterly had acted as a ship's surgeon. Suffers from ague contracted in Africa. On his last sea trip the ship was torpedoed, and so has not risked another voyage. Only income the old-age pension. Voted £6 in six instalments.—L.R.C.S. Irel., L.R.C.P. Edin., aged 74, married, who practised at Wycombe and Marlborough. For the last seven years has suffered from cerebral arterial sclerosis. Wife's income £1 per week, and owing to high price of food unable to pay their way. One married daughter, unable to help. Voted £18 in 12 instalments.—Daughter, aged 60, of L.R.C.S. Edin. who practised at Liverpool. For many years worked as a governess, but had to give it up after a long illness. Only income derived from letting a furnished room in her cottage, but of late has not been successful, and owing to high prices unable to manage. Voted £5.—Widow, aged 48, of M.R.C.S. Eng., who was an army doctor and died in 1905. After death of husband was able to earn a living by needlework and breeding Pekinese dogs, but since the war commenced has not been successful. Only income £30 a year from friend. Not eligible for War Office pension. Two children who can only help slightly. Voted £10 in two instalments.—Daughter, aged 49, of M.D. Glasg. who practised in Ireland and died in 1898. Applicant is a teacher of music, but since the war has not been able to get pupils. Has aged mother, a pensioner of the Fund, who is helpless, and requires her daughter's attendance, which prevents applicant from undertaking work away from home. Voted £5.—Daughter of M.R.C.S. Eng. who practised at Hadleigh. Applicant was a governess for 33 years, but owing to a breakdown in health had to discontinue the work. Income £18 from dividends and £21 pension from another society, and earns a little by needlework. Owing to the high price of food unable to manage at present. Voted £2 and referred to the Guild.—Wife, aged 53, of M.R.C.S. Eng. who practised until recently at Tunbridge Wells. Her husband a few months ago had a paralytic seizure which has left him helpless. His practice, which produced between £500 and £600 a year, has now been sold, and he is to receive one-third of the proceeds for three years, and as the practice was more or less a personal one, less than £100 a year is only expected. There are 11 children, seven of which are at home, and four going to school, and elder ones only able to help very slightly. Voted £2 and referred to the Guild.—Daughter, aged 43, of M.R.C.S. Eng. who practised at Notting-hill and died in 1885. Mother, who for many years was helped by the Fund, has died recently from cancer. Applicant and sister have tried to earn by letting lodgings, but owing to living on the Kent Coast have been unsuccessful lately. Propose giving up house, and try to obtain other work, but want some immediate help. Voted £10.—Widow, aged 30, of L.R.C.P. & S. Edin. who held an official appointment and died in April, 1916. Applicant left with five children, aged 1 to 9 years, and the only money an insurance of £200. Has removed to Scotland, and hopes to be able to make a little by letting furnished rooms. Highly recommended. Voted £10 in two instalments.—Widow, aged 65, of R.A.M.C. officer who died in June of this year. Only income a pension of £34 per annum. Has two children married and unable to help. Long illness of husband, who had to live on his pension for many years. Applicant too old to obtain work, but she is willing to do what she can. Voted £10.—Daughter, aged 64, of L.S.A. Lond. who practised at Sunderland and died in 1883. Applicant with a sister was left unprovided for. The sister was a pensioner of the Fund, and had an annuity from another society, but she died in August, and the applicant, who was dependent upon her, is now penniless and too ill to work. Voted £12 in 12 instalments.—Daughter, aged 48, of M.D. Lond. who practised at Newcastle-on-Tyne. Applicant was left quite unprovided for, and owing to indifferent health of herself and sister unable to work. A friend who used to help unable to do so now owing to depleted income in consequence of the war. Relieved twice (some years ago). Helped by the Guild. Voted £12 in 12 instalments.—Widow, aged 71, of L.R.C.P. & S. Glasg. who practised in East London and died in 1913. Left totally unprovided for at husband's death, who had a long illness. Has four children, three married and unable to help, the other, an invalid daughter, lives with her mother. Has a pension of £30 from a City Company, and her brother and sister help a little. Relieved three times, £36. Voted £12 in 12 instalments.—Daughter, aged 56, of M.R.C.S. Eng. who practised at Newport, Mon., and died in 1892. Since father's death has endeavoured to make a living by keeping a small school, but owing to the increased cost of living unable to make it pay. Relieved once, £12 in 12 instalments. Voted £12 in 12 instalments.—Daughter, aged 46, of M.R.C.S. Eng. who practised at Redcar and died in 1873. Owing to ill-health unable to work, and only income a pension from the R.U.K.B. Assoc. of £21. Mother has £65 per year, but

is an invalid, and a sister, who is a trained nurse, has had to give up her appointment to look after her mother and sister. Relieved five times, £52. Voted £10 in two instalments.—Daughter, aged 60, of M.R.C.S. Eng. who practised at Dorking and died in 1873. Applicant left unprovided for, and is a permanent invalid. Income 5s. a week from another charity, and a friend allows her £25 a year. Relieved four times, £40. Voted £10 in two instalments.—Widow, aged 57, of L.F.P.S. Glasg. who practised at Heaton-on-Tyne and died in 1899. Was left unprovided for with six children, three of whom are now married and unable to help. Two delicate daughters are at home, and help to look after lodgers. Applicant's health bad, so unable to do anything. Relieved 11 times, £118. Voted £12 in 12 instalments.—Daughter, aged 55, of L.R.C.P. Glasg. who practised at Birmingham and died in 1874. Left unprovided for, and tries to earn a living by letting lodgings in Wales, but has not been successful the last few years. Relieved five times, £56. Voted £12 in 12 instalments.—Daughter, aged 51, of L.R.C.P. Glasg., who practised at Glasgow and died in 1897. Up to the commencement of the war managed to earn a living by taking in lodgers and paying guests in her house on the north-east coast of Scotland, and has recently been confined to bed. Relieved twice, £20. Voted £10.—Widow, aged 69, of M.B. Edin. who practised in the Shetland Islands and died in 1907. Applicant has very indifferent health, but has tried to live on her pension of £30 from another medical charity, but owing to the increase in the price of food has got into difficulties. Relieved once, four years ago, £6. Voted £12 in 12 instalments.—M.R.C.S. Eng., aged 81, who is practising in Cornwall, and previously at Nottingham. Lost his practice through the Insurance Act, and during the last 12 months has only earned £34. Relieved twice, £20. Voted £18 in 12 instalments.—M.D. Edin., aged 75, married, who practised for many years in London. Is now suffering from a paralytic seizure and unable to work. Wife's income only £50. Has recently received an Epsom Pension. Relieved once, £18. Voted £18 in 12 instalments.—Daughter, aged 43, of M.R.C.S. Eng. who practised at Peterborough and died in 1907. Applicant left unprovided for. Some years ago the Fund granted money to enable her to qualify for mission work. Her health, however, broke down, and she is now engaged as a clerk at £1 a week. Owing to the increased cost of food finds this insufficient. Relieved once, £20. Voted £7, and referred to the Guild.—Widow, aged 71, of L.R.C.S. Irel. who practised at Watworth and died in 1915. Left unprovided for with one daughter, who is now earning her living as a clerk. Applicant's only income the Old Age Pension. Relieved twice, £14. Voted £12 in 12 instalments.—Widow, aged 62, of L.R.C.S. Irel. who practised in London and died in 1893. Until two years ago applicant managed to earn her own living, but was overtaken by illness and had to be operated upon, and she has been in indifferent health since. A furnished room is provided by friends, but she has no income. Relieved once, £12. Voted £12 in 12 instalments.—Widow, aged 55, of M.B. Durh. who practised at Epsom and died in 1887. Left with two daughters, who were educated by the Guild and are now acting as clerks. Applicant's health has broken down, and she requires help for dentistry and for the purchase of an electrophone for deafness. Relieved twice, £17. The Fund contributed £5 to the Guild towards any assistance they thought desirable.

Subscriptions may be sent to the honorary treasurer, Dr. Samuel West, 11, Chandos-street, Cavendish-square, London, W.

THE MEDICAL SCHOOL OF THE UNIVERSITY OF CAMBRIDGE.—The number of medical students who have entered Cambridge this year is 25, showing a further falling off from the 41 who entered in 1915, the 64 in 1914, and the 116 in 1913.

DONATIONS AND BEQUESTS.—The late Mrs. Laura Catherine Joad, of Patching, near Worthing, left by will £400 to the Worthing Hospital, and £200 each to the Royal Hospital for Incurables, Putney, and the Earlswood Asylum for Idiots.—By the will of the late Mr. Edward Breviss the London Hospital will receive £5000.—The late William P. Lowrie, of Glasgow, has bequeathed £56,000 among various charitable institutions, including £10,000 each to the Glasgow Royal Infirmary and the Glasgow Western Infirmary, and £3000 each to the Glasgow Victoria Infirmary and the Royal Sick Children's Hospital.

ALVARENGA PRIZE OF THE COLLEGE OF PHYSICIANS OF PHILADELPHIA.—The next award of the Alvarenga prize, amounting to about \$250, will be made on July 14th, 1917, provided that an essay deemed by the committee of award to be worthy of the prize shall have been offered. Essays intended for competition may be upon any subject in medicine, and must not have been published. The conditions can be obtained from the secretary, 19, South 22d-street, Philadelphia, Pa., U.S.A.

Dr. E. Walpole-Simmons has been selected at a private meeting of the Worcester city council for the office of city chamberlain, an ancient civic office which dates back for centuries. He has been for some time chairman of the health committee of the city council.

THE Institute of Hygiene is lending its help in the crusade against venereal disease by arranging for an instructive series of lectures at the Institute. These lectures, which are delivered at 4 p.m. each Tuesday, are specially intended for district nurses, health visitors, and midwives. The lectures began on Tuesday last, when Sir Malcolm Morris discussed the relation of venereal disease to public health. Dr. J. H. Eyre, Lady Barrett, and Mr. E. R. Townley Clarkson will continue the series.

EPSOM COLLEGE ROYAL MEDICAL FOUNDATION.—The Council invite applications for a "Christie" pension of £45 a year, and for two "France" pensions of £30 each a year. Candidates must be members of the medical profession who are not less than 60 years of age, and whose income does not exceed £60 a year. Further particulars and forms of application can be obtained from the Secretary, at the office of the College, 37, Soho-square, W.

LONDON HOSPITAL.—A short course of lectures on the "Early Diagnosis and Treatment of Syphilis" will be given by Dr. J. H. Sequeira, physician in charge of the skin department of the hospital, on Thursdays, Nov. 23rd and 30th and Dec. 7th and 14th, at 11 A.M. In connexion with these lectures Dr. J. McIntosh has arranged to give practical demonstrations of the examination for spirochetes and Wassermann test. Members of the medical profession will be admitted on presentation of their cards.

MEDICAL MAYOR.—At a private meeting of the Droitwich town council Dr. P. A. Roden, J.P., was adopted unanimously as the mayor of the borough for the ensuing year. This is the first occasion in the history of the borough that a mayor has been chosen from outside the council. Dr. Roden's father, the late Dr. S. S. Roden, served in the office of mayor for five years, the last four consecutively, when he was an alderman of the borough. Dr. P. A. Roden is the medical officer of the borough and the medical officer of the Droitwich union workhouse.

Parliamentary Intelligence.

HOUSE OF LORDS.

TUESDAY, OCT. 31ST.

The Position in Mesopotamia.

THE EARL OF DERBY (Under Secretary for War) made a statement in regard to the position of affairs in Mesopotamia. In the course of it he said that the situation in regard to supplies was clearly more satisfactory. There was a slight shortage in alternate diets. The fleet of hospital ships had been considerably augmented, and it was now possible to transport the sick and wounded without delay and with reasonable comfort. Some specially fitted hospital ships were being built and expedited, but they would not be available until next year. The medical services had been greatly augmented, and a number of hospitals, medical officers, and nurses had been despatched along with medical stores and outfits. Regarding the amount of sickness it was difficult to give reliable figures. During the period between April 29th and July 29th, 1916, the admissions to hospital of British troops averaged 2739 per week, deaths 108 per week, and numbers evacuated 1048 per week. From August 5th to Sept. 23rd, 1916, the weekly average was: admissions to hospital 1705, deaths 39, and evacuations 738.

HOUSE OF COMMONS.

WEDNESDAY, OCT. 25TH.

T.N.T. Poisoning.

MR. ANDERSON asked the Under Secretary for the Home Department whether he was aware that of the 472 cases of industrial poisoning reported during the nine months ending September, 1916, 120 occurred from toxic jaundice and that, of 62 deaths, 33 were attributable to this cause; whether he could state how many of these cases and deaths were due to poisoning from tri-nitro-toluene; and what action he proposed to take.—MR. BRACE said in reply: The figures are correctly stated in the first part of the question. The number of these cases due to T.N.T. poisoning was 95 and the number of deaths 28. Every possible step is being taken by my department in concert with the Ministry of Munitions to investigate or deal with this disease.

Barrackpore Hospital.

MR. GEORGE LAMBERT asked the Secretary of State for India whether cooling-fans and lighting installations were available for the hospital and barracks at Barrackpore, where West of England regiments were stationed, in India.—MR. C. ROBERTS (on behalf of Mr. CHAMBERLAIN) replied: Electric lights and fans will be installed in the hospital at Barrackpore before next hot weather. The Government of India report that they are taking up electrification schemes as quickly as the staff and materials available permit, the order of urgency being determined by medical authorities.

THURSDAY, OCT. 26TH.

Treatment of Venereal Diseases.

Colonel NORTON-GRIFFITHS asked the Parliamentary Secretary to the Local Government Board whether his

attention had been called to various resolutions passed by public bodies calling for Government action in regard to the increase of venereal disease; and whether immediate steps would be taken with a view to notification and compulsory treatment, thus mitigating the danger arising to innocent persons by contagion and also safeguarding the welfare and health of our troops.—MR. HAYES FISHER answered: My attention has been drawn to the resolutions referred to. As the House is aware, the Government has already taken definite action in accordance with the recommendation of the Royal Commission on Venereal Diseases. That Commission, however, came to the unanimous conclusion that no system of notification of these diseases should be put in force at the present time, and after careful consideration I am satisfied that more progress is likely to be achieved in the immediate future in diminishing these diseases by following their recommendation than by taking the steps indicated in the resolutions.

MR. ANDERSON: Has the right honourable gentleman seen the manifesto signed by Mrs. Pankhurst, Mrs. Lloyd George, and other ladies upon this question, and can he say whether the Government, before they take action, if they do intend to take any action, in the direction of the compulsory notification of venereal disease, will consider that the whole weight of expert evidence is in the direction of showing that this would have exactly a contrary effect, and that it would drive the matter underground, and—

THE SPEAKER: Order, order. The honourable Member is now stating arguments.

Captain C. BATHURST asked the right honourable gentleman whether, as stated in the recently published Women Social Workers' Appeal, venereal disease was certainly spreading in the United Kingdom and affecting a large number of innocent persons; and, if so, whether he would institute compulsory notification and compulsory treatment, as in the case of other dangerous contagious diseases, and at the same time take steps to check the activities of fraudulent persons professing ability to cure the disease, as recommended by the Select Committee on Patent and Proprietary Medicines.—MR. HAYES FISHER answered: On the question of notification I may refer my honourable friend to the reply I have just given. The suggestion contained in the latter part of the question is under consideration.

New Medical Benefit Regulations.

MR. CHANCELLOR asked the Representative of the National Insurance Commissioners whether, in view of the objection by certain sections of the medical profession to Clause 3 of the proposed new medical benefit regulations, he had any method of dealing with the situation in the event of the doctors deciding not to continue service if the clause was maintained.—MR. C. ROBERTS answered: In view of the conferences which have recently taken place, the contingency contemplated in the question is, I think, not likely to arise.

Repatriated Civilians.

MR. HAYES FISHER informed Mr. MALCOLM that the Government Committee on the Prevention and Relief of Distress had made arrangements with the Central Charities Committee for the care of British civilian prisoners released from internment in enemy countries. The Central Charities Committee met them at the port of arrival, afforded temporary assistance and shelter to those in need, arranged for the provision of medical and hospital treatment for sick cases, other than the serious cases which were dealt with by the Red Cross Society, and helped them to obtain employment.

Home Hospital Reserve.

MR. TYSON WILSON asked the Financial Secretary to the War Office whether he was aware that a large number of men who belonged to the Home Hospital Reserve and who had been on duty since the beginning of the war joined this reserve on the understanding that they would be retained for service at the home hospitals, and that many of these men, some of them over military age, were being drafted for service abroad into any unit that the Army authorities selected; and whether, seeing that these men were serving under a special agreement, they had the right of appeal to any tribunal if they objected to serve abroad.—MR. FORSTER replied: The men of the Home Hospital Reserve joined originally for service in hospitals at home. Many of them, however, volunteered for service with armies in the field, and of these a considerable number have been drafted for service overseas in some unit of the Royal Army Medical Corps. Those who did not volunteer have been retained at home.

TUESDAY, OCT. 31ST.

Settlement of Insurance Accounts.

MR. CHANCELLOR asked the representative of the National Insurance Commissioners whether the figures in respect of the final settlement of the remuneration due to doctors for the year 1915 had been furnished to all insurance committees; which insurance committees had distributed the moneys; when the practitioners who had not yet received the

moneys due to them might expect payment; and whether he could do anything to expedite the settlement.—Mr. C. ROBERTS wrote in reply: Figures enabling the final settlement for 1915 to be made have been furnished to all insurance committees in England, and in Scotland and Wales figures enabling further or final payments to be made have been, or will shortly be, furnished to insurance committees in these countries. I am unable to give the particulars asked for in the second part of the question without obtaining a return from all insurance committees, but if the honourable Member has in mind any particular case of delay I will make inquiries.

Industrial Disease.

Mr. ELLIS DAVIES asked the Under Secretary for the Home Department whether disease caused by picric acid entitled the workman affected to compensation under the Workmen's Compensation Act; and, if not, whether he could, in view of the number concerned, add the disease to the Schedule to the Act.—Mr. BRACE replied: The only diseases normally attributable to processes in the manufacture of, or involving the use of, picric acid are eczematous ulceration of the skin, or dermatitis, and poisoning by nitrous fumes. Both of them are scheduled under the Workmen's Compensation Act.

The Notification of Venereal Disease.

Earl WINTERTON asked the Prime Minister whether, in view of the urgency of the matter, he would introduce legislation to make compulsory the notification of venereal disease in all its forms, and criminal its wilful transmission by an infected to a healthy person.—Mr. BONAR LAW (on behalf of Mr. ASQUITH) said: With regard to the first part of the question, I would refer my noble friend to the answers given on behalf of the Local Government Board on Thursday last. The Home Secretary is considering the suggestion contained in the last part of the question.

Treatment of Discharged Soldiers.

Answering Lord H. CAVENDISH-BENTINCK, Mr. LLOYD GEORGE (Secretary for War) said: The War Office is charged with establishing an organisation for the training and treatment of the discharged soldier, and this will be done by means of a civil organisation. The matter is receiving the most careful consideration.

Body-shields for Troops.

Mr. HAZLETON asked the Secretary for War whether there had been any practical outcome of the investigations and experiments into the problem of devising body-shields for the troops at the front; and whether he could say what the present position with regard to the matter now was.—Mr. LLOYD GEORGE replied: A report on the subject has been received from Sir Douglas Haig, and steps are being taken to meet his wishes. It is undesirable to give further details.

WEDNESDAY, NOV. 1ST.

Nurses Registration.

Major CHAPPLE asked the Prime Minister whether, in view of the increasing urgency of enabling those in need of nurses to distinguish those who were fully trained from those who were not, and in recognition of the national work performed by nurses in the care of the sick and wounded, he would bring in a Bill on similar lines to the one submitted to him by the Central Committee for the State Registration of Nurses.—Mr. ASQUITH wrote in reply: This is a highly controversial proposal, as my honourable friend is aware, and I cannot at the present time undertake to introduce it.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

MCKINNEY, B., has been appointed Medical Officer to the Ely Dispensary District by the Enniskillen Board of Guardians.
MITCHELL, ALEXANDER PHILIP, F.R.C.S., Edin., M.Ch. M.D., Interim Surgeon to the Royal Hospital for Sick Children, Edinburgh.
FRANKNELL, J. T., M.D. Glasg., Medical Officer of Health for the Borough of Falkirk.
SAMARAWARA, M. E., M.R.C.S., L.R.C.P. Lond., L.M.S.S.A. Lond., Medical Officer to the Birmingham General Dispensary.
WILSON, J., Certifying Surgeon under the Factory and Workshop Acts for the Irvine District of the county of Ayr.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

When the application of a Belgian medical man would be considered the advertisers are requested to communicate with the Editor.

BIRMINGHAM CITY EDUCATION COMMITTEE.—Temporary Assistant School Medical Officer. Salary £300 per annum.

BRIGHTON, ROYAL SUSSEX COUNTY HOSPITAL.—Junior House Surgeon, unattached. Salary £280 per annum, with board.
BRISTOL GENERAL HOSPITAL.—Casualty House Surgeon. Salary at rate of £175 per annum, with board, &c.
BRISTOL ROYAL INFIRMARY.—House Physician. Salary at rate of £120 per annum, with board, &c.
BURY INFIRMARY.—Senior House Surgeon. Salary £250 per annum, with board, &c.
ILFORD COUNCIL EDUCATION COMMITTEE.—School Oculist. Salary 1½ guineas for each session of two and a half hours.
GLOUCESTER, GLOUCESTERSHIRE ROYAL INFIRMARY AND EYE INSTITUTION.—Surgeon.
HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—Assistant Resident Medical Officer. Salary £103 per annum, with board, &c.
LEICESTER ROYAL INFIRMARY.—Pathologist. Salary £500 per annum.
MANCHESTER COUNTY ASYLUM, Prestwich.—Locum Tenens. Salary £7 7s. per week, with board, &c.
NETLEY, SOUTHAMPTON, WELSH HOSPITAL.—Medical Officer. Salary £400 per annum, with board, &c.
NEW HOSPITAL FOR WOMEN, Roston-road.—Temporary Female Assistant Surgeon for six months. Also Female House Physician, Two House Surgeons, and Obstetric Assistant for six months. Salaries at rate of £50 per annum, with board, &c. Also Anaesthetist. Salary £10 10s. Also Clinical Assistant for Ophthalmic Department.
ROYAL FREE HOSPITAL, Gray's Inn-road, W.C.—Dental Surgeon.
SALFORD UNION INFIRMARY, Hope, Pendleton, near Manchester.—Female Assistant Resident Medical Officer. Salary £250 per annum, with board, &c.
SHEFFIELD, ROYAL INFIRMARY.—Two House Surgeons. Salary £100 per annum, with board, &c.
VENTNOR, ISLE OF WIGHT, ROYAL NATIONAL HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST ON THE SEPARATE PRINCIPLE.—Assistant Resident Medical Officer.
VICTORIA HOSPITAL FOR CHILDREN, Tite-street, Chelsea, S.W.—House Physician. Salary £200 per annum, with board, &c.
WALSALL AND DISTRICT HOSPITAL.—Assistant House Surgeon and Anaesthetist. Salary £175 per annum, with board, &c.
THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Crossgar, in the county of Down, and at Lytham, in the county of Lancaster.

Births, Marriages, and Deaths.

BIRTHS.

BARNES.—On Oct. 24th, at Hill House, Eye, Suffolk, the wife of Lieutenant H. E. Barnes, M.D., R.A.M.C., of a son.
RANKIN.—On Oct. 24th, at Fitzroy-place, Glasgow, Ivy (née Taunton), the wife of Temporary Captain W. Rankin, R.A.M.C., of a son.
ROSE-HUTCHINSON.—On Oct. 28th, at Malabar-hill, Bombay, the wife of Major L. T. Rose-Hutchinson, I.M.S.—a son.

MARRIAGES.

PEARCE GOULD—JACKSON.—On Oct. 25th, at St. Mary's, Betteshanger, Eric Lush Pearce Gould, F.R.C.S., Temporary Surgeon, R.N., to Audrey Mitchell, daughter of the late Mr. Lawrence Jackson, K.C., and of Mrs. Jackson, of Updown, Basingstoke.
PLATT—TURNER.—On Oct. 27th, at Marylebone Parish Church, Harry Platt, M.S., F.R.C.S., Capt. R.A.M.C., to Gertrude S., second daughter of Mr. R. Turney, late of Linslade, Bucks.
THACKER-NEVILLE—TRESHAM.—On Oct. 25th, at St. Paul's, Onalowsquare, William Stewart, M.D. (T.C.D.), F.R.C.S., Edin., of the Church of England Mission, and Union Medical College, Peking, Temporary Captain, R.A.M.C., to Maud, youngest daughter of the late Mr. D. H. Tresham, Beylah Indigo Concern, Benares, India, and of Mrs. Tresham, Purton, Eastbourne, England.

DEATHS.

HUDSON.—On Oct. 14th, at Allahabad, India, Lieutenant-Colonel Ernest Hudson, F.R.C.S., I.M.S., youngest son of Henry Lombard Hudson, late of Harleston, Norfolk.
NICOL.—On Oct. 23rd, died of wounds, Captain C. M. Nicol, M.B., R.A.M.C., D.A.D.M.S., aged 23.
VAUGHAN-HUGHES.—On Oct. 25th, at Cemmas Court, Hemel Hempstead, James Vaughan-Hughes, M.D., L.R.C.P. Lond., aged 95.
WILKINS.—On Oct. 27th, at Stayer House, Eye, Colonel James Sutherland Wilkins, I.M.S., D.S.O., aged 65.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

BOOKS, ETC., RECEIVED.

CHURCHILL, J. AND A., London.
Moore's Manual of Family Medicine and Hygiene for India. Published under the authority of the Government of India. Eighth edition. By C. A. Sprawson, Major, I.M.S. With Foreword by Sir C. Pardey Lukis, Director-General, I.M.S. Price 6s. net.
HEINEMANN, WILLIAM, London.

Notes, Short Comments, and Answers to Correspondents.

ANGIO-NEUROTIC ŒDEMA.

To the Editor of THE LANCET.

SIR,—In answer to the very interesting and typical account of a case of this complaint by Major, R.A.M.C. (T.F.), in THE LANCET of Oct. 7th, and my appreciation of the difficulty in finding just the information one needs in a text-book, I may be forgiven if I go over ground in my reply with which he as a sufferer is more conversant than I am. While the exact pathology has not been made out, it is generally considered to be a vaso-motor neurosis with increased permeability of the blood-vessels and probably a deficiency of calcium salts in the blood, and while it often occurs in persons with a family history of the same complaint or allied complaints, such as erythema, purpura, Raynaud's disease and chilblains, mucous colitis, and neurasthenia; this family history is certainly not always the case. I have found by careful observation that from time to time in these cases a slight mitral or tricuspid murmur can be detected and that the blood pressure is almost always very low up to about 110 mm. of Hg for ages up to 45 or more, and that slight traces of albumin occur in the urine with fair regularity, and that at least 50 to 65 per cent. of the cases have gastro-intestinal disturbances. The following is an interesting case or set of cases:—

The brother of two patients of mine was invalided home from the East with "dysentery" attacks of hæmorrhage of the bowels. I had met him at a social function, and he had conversed freely with me about his complaint, but did not see him to speak to again, but heard of his progress. After being treated in a nursing home in London for some months for dysentery, he went to Bath, where a diagnosis of appendicitis was made and the appendix removed. Still he got no better and eventually he gave up treatment and took a holiday and went fishing. This did him a lot of good, and the last I heard of him was he was still much better. Personally, from his history I doubted both diagnoses and told the relatives so, on their asking me what I thought; and the bacteriologist who examined his feces, on my saying I did not think he had found either amoebic or bacillary dysentery said: "That was so." This was while the attacks were on.

Both his relations, my patients, had very low blood pressures, suffered from chilblains very badly, and one had been the subject of very severe attacks of angio-neurotic œdema for over 14 years before I treated the case. Had attacks of diarrhoea from time to time, and severe facial attacks coming on occasionally in the latter half of the nights, and looking as if "just out of the ring from prize-fighting," the features being entirely obliterated.

Sargent and Russell, in their excellent work, mention this complaint and its allied forms as a possibility that must never be lost sight of when investigating a case of acute abdominal symptoms. Most sufferers, I find, are anæmic, but some are ruddy and gouty. Apart from the constitutional tendency to it, consisting of low blood pressure and want of coagulability of the blood, anything which tends to produce neurasthenic conditions tends to bring this on, and therefore one should try to live under the best possible hygienic conditions, avoiding excesses of any kind, errors in dietary, and giving strict attention to the state of the bowels. An entire change often does good, as in the first case mentioned. Those foods which bring on urticaria certainly bring this on, and over-brewed tea is one, and a patient in whom I traced this and who took such tea daily was not discomforted by weak, freshly made, China tea. Again, tobacco is a very common source of trouble, and one patient I had who "never smoked more than three cigarettes a day" got great relief by abolishing smoking altogether. Apart from gastro-intestinal irritants and alcohol, gout, malaria, and syphilis certainly have been at the root of the trouble. One dose of salvarsan has completely stopped it in a case of the latter, and colchicum and quinine gave benefit in the former two sources of trouble.

In uncomplicated cases almost all the remedies used aim at the vaso-motor system, and it is interesting to note that both vaso-dilators and vaso-constrictors are prescribed, such as thyroïdin, nitroglycerine, pituitrin, adrenalin, the last two being specially useful in the attacks. As with everything else, if the cause can be found the treatment becomes easy, but I do not think any one irritant or article of diet can be said to be the sole cause of attacks. Nuts certainly act in some persons as a gastric irritant, and the fact of its "coming on three days after eating nuts," reminds me, some years ago when attending boys in a large private boarding school and when called in to attend cases of catarrhal jaundice, I always counted three days back in my mind and then mentioning the day of the week to the boy, said: "See, you had nuts on — day." After a little reflection, "cocoanuts" were mostly to blame, other times smaller nuts were owned up to. Strawberries, shell-fish, salmon, all in turn affect some. So far as my experience goes, I have found treating the patients for their anæmia with iron and arsenic; for the low

blood pressure, with tincture of strophanthus and nuxvomica with either alkalies or acids (as indicated by the case under consideration) for three weeks to six weeks at a time, one such course at least every three months, alternately with a course of calcium chloride gr. x. to xx. t.d.s. (or calcium lactate gr. xx. to xxx. t.d.s.) give the best results. Iron glycerophosphate and its calcium salt are excellent for a change.

It is interesting to note with regard to "Major's" experience that it has recently been pointed out that there is a deficiency of lime salts in the food supplied to troops in war time and that this accounts for the prevalence of enteric and dysentery; and certainly I believe one finds a deficiency of lime salts in all cases of abnormal permeability of the vessels, and the benefit of calcium is shown in cases of chilblains and "bleeders." The value of a course of high-frequency in these cases has been testified to by several writers, and during an attack I know of nothing that stops the pain so quickly as the high-frequency effluve, vacuum or brush, the former for face chiefly. During an attack brisk salines, hot alkaline baths, calcium lactate 3i., repeated in two hours if necessary, adrenalin, and pituitrin are the most useful. Specially useful as articles of diet are peas, beans, eggs, butter, and milk, all containing lime salts.

I am, Sir, yours faithfully,

G. HERBERT RUTTER.

Bournemouth, Oct. 14th, 1916.

THE REPATRIATION OF GERMAN CIVILIANS.

Lord Robert Cecil stated last week in the House of Commons that an arrangement had been made whereby all civilians over the age of 45 interned in Germany or the British Empire would be repatriated subject to the right of either Power to detain for military reasons not more than 20 persons. Doubtless the great majority of interned British subjects will desire to avail themselves of this opportunity. With regard to interned German subjects, where, as in many instances, they have resided for years in this country and have British-born wives, the case is different. We understand that the repatriation is not compulsory and that any interned civilian has the right of appeal against it, and if the appeal is allowed he remains interned. Political refugees are not forcibly repatriated. An appeal to remain from a German civilian with a British-born wife is readily granted. If the man goes and his wife remains behind she loses the Government grant. This now amounts to 11s. 6d. weekly in London and 9s. 3d. in the country, with 1s. 9d. extra for each child, which may be raised to 2s. 6d. at the discretion of the guardians.

A GOLD COAST DRUG.

THE Blue-book of the Gold Coast Colony for 1915 contains the following reference to a sample of bark of colonial growth sent to the Imperial Institute for investigation in the Scientific and Technical Research Department:—"A sample of bark was identified as probably that of *Zanthoxylum senegalense*, D.C. The bark, which has stimulant properties and is employed locally in rheumatic affections, intestinal troubles, and other diseases, has been previously examined by various investigators and found to contain a fixed oil, a neutral body, and two alkaloids, one of which (artarine) was found to be present to the extent of 0.4 per cent. This drug is described as producing muscular irritation and physiological disturbances similar to those induced by veratrine. The root bark of *Zanthoxylum senegalense* also yields a fixed oil which (probably on account of the artarine dissolved in it) tends to produce paralysis of the nervous system." Although there is not any regular demand for this bark in Europe, it is possible that if the alkaloid artarine could be shown to be clearly analogous to veratrine in physiological activity it might replace the latter in medicine. It was therefore wisely suggested that a quantity of the bark should be sent to the Imperial Institute for investigation.

THE PROLIFICITY OF OPPOSITE TWINS.

To the Editor of THE LANCET.

SIR,—In England it is a popular and widely-known belief that in the case of twins of opposite sexes the girl is invariably sterile. In fact, I was asked to consider my own marriage in this direction. However, my wife, though such a twin, has presented me with five healthy children.

I am, Sir, yours faithfully,

M.D.

Zürich, Oct. 25th, 1916.

X RAY APPARATUS AND ACCESSORIES.

WE have received an interesting catalogue (B) of X ray apparatus, tubes, and accessories from Messrs. R. Butt and Co., Ltd., of 147, Wardour-street, London, W. There are some admirable illustrations made from the actual X ray tubes and apparatus kept in stock. As improvements are made they are adopted, this firm being their own manufacturers. The descriptive matter is well written and contains some useful practical information.

ESPERANTO AND RUSSIAN.

MEMBERS of the Tutmonda Esperanta Kuracista Asocio (Universal Esperanto Medical Association), which has the names of several English medical men on its roll, will be interested in a letter which appears over the name of Mme. Sujadinoff in a Russian Supplement published recently by the *Times*. The study of Russian is now the subject of considerable attention, and the matter of transliteration has been much discussed in the public press, and the *Times* has now adopted a scheme, admittedly not perfect in all its details, for the Russian section of that paper. In the letter referred to above Mme. Sujadinoff points out that every letter of the Russian alphabet can be exactly represented by the use of Esperanto, illustrating her statement by a parallel comparison of the two alphabets. She also advises those who intend to learn Russian to facilitate their task by taking a preliminary course in Esperanto. That the one language should particularly help in the acquisition of the other is not at all remarkable, seeing that Dr. Zamenhof, the inventor of Esperanto, is a Russian.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

The following journals, magazines, &c., have been received:—*Medical Journal of South Africa*, *Annali di Medicina Navale e Coloniale*, *Midland Medical Journal*, *Proctologist and Gastroenterologist*, *Archives of Internal Medicine*, *Pacific Medical Journal*.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.

THURSDAY.—Papers:—Prof. W. M. Bayliss: Method of Raising a Low Arterial Pressure.—Mr. A. J. Brown and Mr. F. Tinker: Selective Permeability: the Absorption of Phenol and other Solutions by the Seeds of *Hordeum vulgare*.—Mr. C. Shearer: On the Toxic Action of Dilute Pure Sodium Chloride Solutions on the Meningococcus.—Mr. C. Shearer and Mr. H. W. Crowe: The Role of the Phagocyte in Cerebro-spinal Meningitis.—Mr. S. B. Schryver and Mary Hewlett: Investigation dealing with the Phenomena of "Clot" Formations. Part IV., The Diphasic Krovisic Action of Salts on the Chocolate gel. (communicated by Prof. V. H. Blackman).—Mr. Ingvar Jorgensen and Mr. F. Kidd: Some Photochemical Experiments with Pure Chlorophyll and their bearing on Theories of Carbon Assimilation (communicated by Prof. V. H. Blackman).

MEETINGS OF SECTIONS.

Thursday, Nov. 9th.

BALNEOLOGY AND CLIMATOLOGY (Hon. Secretaries—Chas. W. Buckley, J. Campbell McClure); at 5 P.M.

Discussion:

On "The Treatment by Physical Methods of Medical Disabilities Induced by War." In which Dr. Gordon, Sir John Collie, Major S. A. Smith, D.S.O., C.A.M.C., and Captain D. A. Clark, C.A.M.C., of the Special Canadian Hospital, Ramsgate, Major Black, Command Depot, Heaton Park, Captain Sawdon, C.A.M.C., Buxton Special Canadian Hospital, Dr. Humphris, Dr. King-Martyn, Bath, Dr. Nunneley, Brighton, and others will take part.

Members of other sections, especially of the MEDICAL, SURGICAL, NEUROLOGICAL, and ELECTRO-THERAPEUTICAL SECTIONS, are invited to be present.

N.B.—Will members please note that the meeting will be held at 5 P.M. (instead of 5.30.).

(At 7.30 P.M. the members will dine together at Pagan's Restaurant, Great Portland-street, W., and members may bring guests. Members who wish to dine are requested to send their names to Dr. J. Campbell McClure, 59, Harley-street, W.)

Friday, Nov. 10th.

CLINICAL (Hon. Secretaries—David Forsyth, T. P. Legg); at 8 P.M.

Cases:

Dr. H. Batty Shaw: Two Cases of Congenital Heart Disease showing Pulmonary Hypertrophic Osteoarthropathy.
Dr. F. Parkes Weber: (1) Progressive Spinal Muscular Atrophy (Duchenne-Aran) following Electric Shock; (2) Thrombo-angitis Obliterans (Non-syphilitic Arteritis Obliterans of the Hebrews) affecting Three Limbs; (3) Chorea Rhythmica in a Man.

RÖNTGEN SOCIETY, Institution of Electrical Engineers, Victoria Embankment, W.C.

TUESDAY.—8.15 P.M., General Meeting. Capt. C. T. Holland: Presidential Address.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East.

TUESDAY.—5 P.M., Horace Dobell Lecture:—Dr. H. R. Dean: The Mechanism of the Serum Reaction.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

Course of Lectures on the Anatomy of the Human Body, for First-aid and Ambulance Students:—

MONDAY.—5 P.M., Lecture III.:—Prof. A. Keith: The Lungs and Trachea.

WEDNESDAY.—5 P.M., Lecture IV.:—Prof. A. Keith: Respiration.

FRIDAY.—5 P.M., Lecture V.:—Prof. A. Keith: The Brain.

Anatomical Preparations and Specimens used for illustration will be on exhibition in the Theatre from 3 P.M. to 5 P.M. on each lecture day, and between 10 A.M. and 5 P.M. in the Hall of the Museum on the following day.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simson: Diseases of Women.

TUESDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Fernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Dr. Simson: Diseases of Women.

THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Simson: Gynecological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Fernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10.30 A.M., Surgical Out-patients (Mr. E. Gillespie). 2.30 P.M., Medical Out-patients (Dr. T. R. Whiphram); Gynecological Out-patients (Dr. Banister). 3 P.M., Medical In-patients (Dr. R. M. Leslie).

TUESDAY.—2.30 P.M., Surgical Operations (Mr. Carson). Clinics:—Medical Out-patients (Dr. A. G. Auld); Surgical Out-patients (Mr. Howell Evans); Nose, Throat, and Ear Out-patients (Mr. C. H. Hayton). Radiography (Dr. Metcalfe). 3.30 P.M., Medical In-patients (Dr. A. J. Whiting).

WEDNESDAY.—Clinics:—2.30 P.M., Throat Operations (Mr. C. H. Hayton). Children Out-patients (Dr. T. R. Whiphram); Eye Out-patients (Mr. R. P. Brooks); Skin Out-patients (Dr. H. W. Barber). 5.30 P.M., Eye Operations (Mr. R. P. Brooks).

THURSDAY.—2.30 P.M., Gynecological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patients (Dr. A. J. Whiting); Surgical Out-patients (Mr. Carson); Radiography (Dr. Metcalfe). 3 P.M., Medical In-patients (Dr. R. M. Leslie).

FRIDAY.—2.30 P.M., Surgical Operations (Mr. Howell Evans). Clinics:—Medical Out-patients (Dr. A. G. Auld); Surgical Out-patients (Mr. H. Gillespie); Eye Out-patients (Mr. R. P. Brooks).

THE THROAT HOSPITAL, Golden-square, W.

MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.

THURSDAY.—5.15 P.M., Clinical Lecture.

CHADWICK PUBLIC LECTURES.

THURSDAY (at the Norwich Museum).—3 P.M., Dr. C. Porter: The Health of the Future Citizen—Lecture II., Babyhood and the Baby (illustrated with lantern slides).

FRIDAY (at the Lecture Room of the Royal Society of Arts, John-street, Adelphi, W.C.).—5.15 P.M., Professor William Stirling: Fatigue, and its Effects on Industry and Efficiency—Lecture III., Fatigue—a Universal Phenomenon of Life (illustrated with lantern slides).

INSTITUTE OF HYGIENE, 33-34, Devonshire-street (Harley-street), W.

TUESDAY.—4 P.M., Dr. J. W. H. Eyre: Venereal Virus and its Detection.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners. Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

Offices: 423, STRAND, LONDON, W.C.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

Subscribers abroad are particularly requested to note the rates of subscriptions given on page 6.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the rates shown, whatever be the weight of any of the copies so supplied.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Stewart's Instruments.)

THE LANCET Office, Nov. 1st, 1913.

Williams, Reading; West Bromwich District Hospital, Secretary of; Messrs. W. Wood and Co., New York; Captain T. Warrington, R.A.M.C.

The Bradshaw Lecture

EXOPHTHALMIC GOITRE.

Delivered before the Royal College of Physicians of London on Nov. 2nd, 1916,

By HECTOR MACKENZIE, M.A., M.D. CANTAB.,
F.R.C.P. LOND.,

PHYSICIAN AND LECTURER ON MEDICINE TO ST. THOMAS'S HOSPITAL,
LONDON; CONSULTING PHYSICIAN TO THE BROMPTON HOSPITAL
FOR CONSUMPTION.

MR PRESIDENT AND GENTLEMEN,—I must first say how sensible I am of the honour which has been done me in conferring on me the privilege of delivering this lecture. The subject I have chosen for the lecture is one which has interested me for many years. This is not the first time that it has been selected for the Bradshaw Lecture, but I may perhaps succeed in presenting the subject from a different point of view and in bringing some of the problems connected with it up to date.

INCIDENCE OF THE DISEASE.

During the four years 1911-14 the number of deaths returned in England and Wales as resulting from exophthalmic goitre was 1558 for females and 155 for males. This gives a proportion of 10 females to 1 male. The age-distribution is given for the years 1912-14, and is as follows:—

| Under 5 | 5-10 | 10-15 | 15-20 | 20-25 | 25-30 | 30-35 | 35-40 | 40-45 | 45-50 | 50-55 | 55-60 | 60-65 | 65-70 | 70-75 | 75-80 | 80-85 |
|---------|------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|
| 1 | 6 | 43 | 92 | 93 | 115 | 144 | 33 | 163 | 124 | 76 | 9 | 1 | 22 | 4 | 2 | |
| — | — | 4 | 13 | 7 | 7 | 14 | 12 | 15 | 12 | 16 | 9 | 7 | 1 | 1 | 1 | |

Totals: Females (first line)—1173; Males (second line)—119.

It will be seen from this that the number of deaths in each five-year age-period increases up to 35-40, and the largest number of deaths occurs between 45 and 50. More persons died from the disease over 65 than under 20.

I have collected the records of 438 cases, of which 263 were seen at St. Thomas's Hospital and 175 were private cases. There were 393 female cases and 45 male. Among these cases I have been careful to include no doubtful or incomplete cases. The age-distribution at the onset of the disease was as follows:—

A. Hospital Cases: 239 Females; 24 Males.

| Ages. | 10- | 15- | 20- | 25- | 30- | 35- | 40- | 45- | 50- | 55- | 60- | 65- | 70- |
|-------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| Females ... | 2 | 50 | 71 | 44 | 29 | 19 | 15 | 4 | 3 | 1 | 1 | — | — |
| Males ... | 0 | 4 | 5 | 3 | 3 | 4 | 1 | 1 | 2 | 0 | 1 | — | — |

Among these cases there were 43 fatal cases, 39 females and 4 males, and the age-distribution at death of these was:

| 10- | 15- | 20- | 25- | 30- | 35- | 40- | 45- | 50- | 55- | 60- | 65- | 70- |
|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| 0 | 8 | 15 | 5 | 8 | 2 | 4 | — | 1 | — | — | — | — |

B. Private Cases: 154 Females; 21 Males.

| Ages. | 10- | 15- | 20- | 25- | 30- | 35- | 40- | 45- | 50- | 55- | 60- | 65- | 70- |
|-------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| Females ... | 0 | 10 | 25 | 24 | 22 | 20 | 19 | 15 | 12 | 3 | 1 | — | 1 |
| Males ... | 0 | 0 | 5 | 5 | 4 | 1 | 3 | 3 | — | — | — | — | — |

It will be observed that in half of the hospital cases the disease had its onset before the age of 25 years, but of the private cases less than a quarter began before this age. The private cases are fairly evenly distributed over the various age-groups. It will be observed also that in more than half of the fatal hospital cases the age at death was under 25, a contrast to the Registrar-General's fatal cases, of which in only one-eighth was the age under 25.

The disease is very rare in childhood, and I have not yet seen a typical case under the age of 12. Among my 438 cases only 2 commenced under the age of 15. Out of No. 4863.

the 1290 fatal cases 6 were between 10 and 15, and 1 was reported under 5; the occurrence of the disease in children as young as two and a half years has, however, been recorded more than once.

RELATION OF MENTAL DISTURBANCE.

One of the remarkable features of the disease is the disproportion between the numbers of the two sexes which are affected, and while this is true of other diseases of the thyroid gland, such as myxœdema and cretinism, the difference is not in their case so strongly marked. We have seen above that the returns of the Registrar-General for fatal cases give a proportion of 10 females to 1 male. The clinical cases which I have collected show 393 females to 45 males, a proportion of 9 females to 1 male. It is a matter of universal experience in this country that the disease is comparatively very rare in the male sex, and I doubt the accuracy of statistics from other countries which give a much larger proportion of male cases. Among other diseases which fall with special weight on the female sex are chlorosis, chorea, and osteoarthritis. Chlorosis may be said to be entirely a female disease. Chorea affects between three and four times as many females as males, and, like exophthalmic goitre, often has as exciting cause some emotional disturbance. Its greater prevalence in the female sex, like that of exophthalmic goitre, is no doubt due to the greater inherent instability of the emotional nervous system. The greater incidence of osteoarthritis on the female sex is perhaps connected with pelvic disorders in the female, but it is interesting that the association of Graves's disease with, or its affinity to, osteoarthritis has been the subject of papers by Spender¹ and Llewellyn Jones.² I cannot say, however, that I have seen many instances of this association myself. The very unequal incidence of exophthalmic goitre in the two sexes is against the supposition that the disease depends on microbic or other infection.

The tendency of the disease to show itself in several members of the same family is well known. In 7 of my cases the mother was affected with the same disease, and in 3 cases the father. In 12 cases the disease affected one sister of the patient, in 3 cases two sisters, in 1 case three sisters, in 1 case one brother, in 2 cases two brothers, in 3 cases an aunt, in 4 cases, a cousin, in 1 case two cousins, in 1 case a grand-aunt, and in 3 cases a daughter. In 1 case a mother, in 1 case a daughter, and in 1 case a sister were affected with myxœdema. The family history has been better worked out among the private cases than among the hospital, for of these examples 34 occurred among the private cases and only 10 among the hospital cases.

The onset of the illness was preceded by some more or less severe mental shock or strain, worry or anxiety, in at least a third of the cases. A history of this was obtained in rather a larger proportion of the private cases than of the hospital cases. In 26 cases there was a history of the sudden death by illness or accident of a near relation or of the death of several near relations in a short time. The husband died suddenly in 6 cases, the father in 2. The father dropped down dead in the patient's presence or some near and dear relation, such as a brother or child, was killed in an accident or drowned or lost in a submarine. In one case a woman lost her husband, two children, and father and mother within a year; in another the son, father, and sister. There was anxiety over the serious illness of near relations, such as husband, father, mother, or child, in 10 cases. In 1 case it was looking after a husband with general paralysis of the insane for three years. There was a history of worry and strain in 18 cases; this was especially common in the male cases. The occupation in a number of cases was one involving special responsibility. One man was secretary to a waterworks company, and the waterworks broke down. Another was a schoolmaster and had an anxious time with the illness of one of his favourite pupils. Serious money losses were only given as a cause in one instance.

There was some kind of shock or fright, such as fire or alarm of fire, horse running away, gas explosion, in 20 cases. There was a history of preceding accident in 9 cases, such as a bicycle accident or a fall from a horse. In 7 cases the onset followed some more or less severe operation, and in 6 cases it followed prolonged or bad confinements. Some had more than their

¹ Brit. Med. Jour., 1891, vol. i, pp. 1169-71.

² Ibid., 1903, vol. i, pp. 1015-17.

share of trouble. One woman had been ill-used by a drunken husband; her mother had suddenly died in her presence, and she had had a fall downstairs followed by a miscarriage.

Examples of Rapid Onset after Mental Disturbance.

As a rule the symptoms of the disease developed gradually after the shock or strain, but in some cases the symptoms very quickly followed the mental disturbance, and of this rapid mode of onset the following are two typical examples.

1.—A mechanical engineer aged 23, who had always enjoyed good health, went to attest on Dec. 11th, 1915, with the object of joining the Royal Naval Air Service, and told the recruiting officer that that was his desire. He passed the doctor successfully and was told he was "A.1." He was then informed that he was now a soldier in the Army. He was very angry at this and went home in a highly excited condition, but soon returned to the recruiting station to try to get transferred into the Air Service. He was told it could not be done. He had no sleep all night and was still in an excited state next day. As the days went on he altered very much in temperament and became cantankerous and quarrelsome, even disputing with people in church. His heart would beat night and day as if he had been running a race, and he developed constant fidgety movements and there was continual trembling of the body. He rapidly became thinner, in spite of an enormous appetite and a great craving for meat. His eyes, too, soon became very prominent and the neck swollen.

I saw the patient about three months after the onset. It was then a typical case of Graves's disease. The most striking feature was very tumultuous and rapid action of the heart, but there were also marked tremor of the hands, general but moderate enlargement of the thyroid, and moderate proptosis. He seemed at this time to be improving, for the eyes were said to be less prominent and less "wild-looking" than they were soon after the upset.

2.—A man, aged 31, a policeman, was brutally attacked by the friends of a culprit whom he was trying to arrest. He was knocked down and kicked in the abdomen and badly bruised about the legs and ankles. He was confined entirely to bed for a week, and eight weeks later, as he was still ill, he was admitted to my ward. Since the attack he had become very nervous, trembled on the slightest excitement, and also suffered from fits of giddiness in which he with difficulty saved himself from falling. He had lost nearly a stone in weight and had not recovered his strength. When first admitted there was only slight exophthalmos. The pulse at rest was 84 but readily quickened to about 100, and there was some tremor of the hands. The thyroid gland was not appreciably enlarged at this time, but three weeks later there was palpable and visible general enlargement. The exophthalmos was marked, the eyes were staring, and the conjunctivæ glistening. The pulse-rate averaged 90 to 100.

Effects of Sorrow and Grief, Anxiety, and Fear.

The effect of profound emotional disturbance in producing exophthalmic goitre is of very special interest in the troubled and distressful times we are now passing through. Every day brings fresh sorrow to thousands. Grief and anxiety are weighing down the hearts of countless mothers, wives, and sisters. While the women of this country have shown a fortitude and endurance beyond all praise it cannot but happen that the terrible ordeal which they have gone through will produce in some more than a passing effect on the emotional nervous system. I think we shall undoubtedly see in the near future an increased number of cases of exophthalmic goitre.

It has been said that anger is a short madness and fright may be said to be a short attack of exophthalmic goitre. The effects of intense fear, the palpitating heart, the trembling, the starting forward of the eyes, the sweating of the body have been pictured for us by great poets as well as by distinguished naturalists. The ghost in *Hamlet* says:

"I could a tale unfold, whose lightest word
Would harrow up thy soul; freeze thy young blood;
Make thy two eyes, like stars, start from their spheres."

In the great Hebrew epic Eliphaz the Temanite says:

"Fear came upon me, and trembling, which made all my bones to shake. The hair of my flesh stood up."

And Elihu says:

"At this also my heart trembleth and is moved out of his place."

The Psalmist plaintively laments:

"I am feeble and sore broken. I have roared by reason of the disquietness of my heart. My heart panteth, my strength faileth me."

"My heart is sore pained within me. Fearfulness and trembling are come upon me and horror hath overwhelmed me."

In these passages we see a reference to the protrusion of the eyes, the trembling, the palpitating, and the loss of strength which make up the picture of exophthalmic goitre.

The effect of emotional disturbance in causing a swelling of the thyroid gland is not so well known. The very existence of the thyroid gland is unknown to the laity. But there is, I think, a reference to the swelling of the thyroid in the words *anguish*, *anxiety*, *anger*, which all imply a feeling of compression of the throat. Perhaps the popular consciousness of a lump in the throat or of the heart being in one's mouth is really due to a temporary fullness of the thyroid. That sometimes the neck in the adult female may become temporarily swollen under excitement was known to the ancients.

But while emotional disturbance appears to be the starting point in a considerable number of cases, it must be admitted that no such cause can be traced in many cases of the disease. The disease may come on slowly or rapidly, and sometimes the protrusion of the eyes, sometimes the swollen neck, sometimes the palpitating, and sometimes the nervousness is the first intimation to the patient or the friends that anything is amiss. From what we know of the causation of the disease we recognise that prevention is beyond our power. As far as possible persons in whom there is a family history of the disease should steer clear of occupations involving more than ordinary responsibility, worry, or anxiety.

PERSISTENT THYMUS GLAND.—CONDITION OF THYROID.

During the last 36 years there have been exactly 36 post-mortem examinations at St. Thomas's Hospital on cases of exophthalmic goitre which gives an average of one a year, but 28 of these have occurred during the last 16 years and only 8 in the preceding 20 years.

The most constant feature next to the enlargement of the thyroid gland is the presence in most of the cases of a persistent or enlarged thymus gland.

The presence of the thymus was noted in 26 cases, and it was described as greatly enlarged in 6 cases, large or hypertrophied in 16, and persistent but not large in 4. In 2 more a little thymic tissue was found in the situation of the gland, and in 1 the atrophied remains of the thymus were noted. In 7 cases out of 36 there is no mention of the thymus, but it is possible that in some of these cases it may have been present although not found. The persistence of the thymus in exophthalmic goitre has long been recognised. The weight of the persistent thymus varied from 1½ to 4½ ounces, and its length was sometimes 4 or 5 inches. The gland in some cases was noted as forming a prominent fleshy mass above the heart or behind the manubrium, or as spreading down in a thick mass to the pericardium, or as stretching down and spread out over the pericardium, or as mingling with the fat of the anterior mediastinum. On microscopical examination Hassall's corpuscles were generally numerous, sometimes of great size, and in all stages of degeneration. Sometimes eosinophiles were numerous. It was noted in some cases that although the gland was large it showed the histological changes not of actively enlarged gland, but rather those of degeneration or some degree of fibrosis was present, but in other instances it was remarked that the gland would be considered normal for a child. In the 3 cases where only an atrophied remnant or a small quantity of glandular tissue was found, in 2, aged 23 and 36, the disease had lasted four years at the time of death, and in the other the disease had started at the age of 20 and gone on with relapses until the age of 29. The oldest subject with a persistent thymus was a woman aged 41. The oldest subject with a large thymus was a woman aged 33. Fourteen of the subjects with a large thymus were between the ages of 18 and 24 and 7 between the ages of 29 and 33.

There were only four post-mortem examinations on persons over 40, and in only one of these was a persistent thymus noted. Professor W. S. Halsted has recorded a case where a woman, aged 47, who died 30 hours after a thyroidectomy was found to have a large thymus extending from the top of the manubrium to, and partly covering, the auricles of the heart.

What part the persistence of the thymus gland plays in the disease is at present uncertain. The possible relationship of exophthalmic goitre to the condition known as

lymphatism or status lymphaticus has to be considered. In this condition, as is well known, there is a dangerous state of weakness of the heart and lowering of the power of resistance. Many cases have been reported of death from chloroform or other anæsthetic, and fatal syncope may occur from some slight cause. It is significant that a persistent thymus is found in so large a proportion of the cases of exophthalmic goitre which succumb under operation. The status lymphaticus, however, is a condition which is more frequent in males than females in the proportion of about 10 to 7, and if persons with the status lymphaticus are specially predisposed to exophthalmic goitre one would expect the number of male cases to be greater than it is in the latter disease.

In 10 cases the thyroid gland was described as much enlarged, weighing from 4½ to 7 ounces. In 14 cases it was simply said to be large. It was slightly or moderately enlarged in 5 cases. In 4 cases there is no special remark about its size. In 2 cases it was described as surrounding and constricting trachea and œsophagus. In one of these cases the lobes met behind, the trachea was compressed laterally, the cartilages being softened and in places almost destroyed. In another case there was also lateral compression of the trachea, and in a case in which the right lobe had been surgically removed the greatly enlarged left lobe lapped round the pharynx. In 2 cases a large number of cysts were present varying in size, and the surface on this account was irregular. The microscopical appearances were in most cases those which are considered typical of Graves's disease and which are fully described elsewhere.

In 3 of the fatal cases the duration of the disease was less than six months, in 10 it was from six months to one year, in 12 from one to two years, in 8 from two to six years, and in 6 over six years. In more than half of the cases the duration was less than 18 months.

COURSE OF THE DISEASE.

With regard to the symptoms of exophthalmic goitre these have been so often and so well described that I need not dwell on them now. I may briefly refer to the blood picture which is fairly constant in typical cases of the disease and may be a help in diagnosis in doubtful cases. Nothing abnormal is usually observed in the case of the red corpuscles, but with regard to the white cells leucopenia is the rule with a relative lymphocytosis. There is no absolute increase in lymphocytes; it is the deficiency of the polynuclears which brings about the leucopenia. Such a blood picture is, however, by no means peculiar to exophthalmic goitre, but is also found in myxœdema, acromegaly, and, in fact, in any disease of the glands of internal secretion.

The attention which has been directed to the rôle played by the thymus in exophthalmic goitre has prompted the search for functional tests which would reveal the presence of overactivity on the part of the thyroid gland. Such tests, if of proved value, would assist in the diagnosis of incomplete, doubtful, or early cases of exophthalmic goitre. All except two are too complicated to be of practical value. 1. Claude Baudouin and Porak³ have investigated the action of hypodermic injection of extract of the posterior lobe of the hypophysis. In the case of normal subjects the pulse becomes accelerated within a few minutes after the injection and returns to normal in about twenty minutes. In exophthalmic goitre, on the other hand, the injection quickly slows the pulse, although only to a slight extent, the effect passing off in 7 or 8 minutes. 2. Loewi's⁴ adrenalin test is the dilatation of the pupil which follows the installation of 1-1000 solution of adrenalin into the conjunctiva in exophthalmic goitre. It has also been found positive in diabetes.

It has always seemed to me a somewhat remarkable feature of exophthalmic goitre that the severity of the illness does not bear any constant relation to the size of the thyroid. Some of the cases with a much enlarged thyroid are not of a severe type, while others in which the thyroid is scarcely or not at all palpable are of quite an acute type. I have seen several cases with extreme exophthalmos, marked nervousness, wasting, and tachycardia without thyroid enlargement. One must take it that size is not a measure of activity. In 2 cases which terminated fatally there was rapid diminution in the size of the thyroid during the few weeks preceding death.

Both these cases were also remarkable for the degree of general body wasting which took place. In one case the patient weighed 8 st. 9 lb. on admission to the hospital and ten weeks later, shortly before death, she weighed only 5 st. 6 lb. Vomiting was a marked feature of this case. Although the thyroid in these cases much diminished in size, it was found at the post-mortem to be still larger than normal. One was described as twice as large as normal, the other slightly enlarged and weighing 1½ ounces.

The degree of wasting which sometimes takes place in exophthalmic goitre is extraordinary. I could give many illustrations of this. Wasting is generally an unfavourable symptom, while gain of weight is favourable, but even extreme degrees of emaciation may be recovered from, of which the following is a typical example.

A woman age 41 was admitted to hospital in 1907 with 11 months' history of illness following influenza. She was very emaciated, weighing 4 st. 5 lb., her ordinary weight being 6 st. 13 lb. dressed. For nine months she had been unable to walk. She had distinct proptosis, slight swelling of thyroid, tremor, and rapid cardiac action. She had been delirious at night for five months before admission, and she had incontinence of urine and bacilluria with some pyrexia. She continued to lose weight for the first four weeks, and her weight fell to 3 st. 12 lb. She was given rotagen 3ss. b.d. for six weeks and then 3i 4tis horis for four weeks more. She remained in hospital 7½ months, and gradually improved. On leaving, her weight was 6 st., but her pulse was still quick.

The long duration and very slow progress in some cases is illustrated by the following examples:—

1. The patient, a married woman, when I first saw her was aged 50. She was complaining of palpitation and tiredness. She had a moderate goitre and a moderate degree of proptosis. Her pulse-rate was 120. She said the prominence of the eyes had gradually been coming on for ten years. Six or seven years ago she began to feel a throbbing in the throat, but she was not aware of the presence of a goitre until four years ago. She was thin and she said she had fallen away very much. She remained under treatment for six months without much change. I saw her next nine years later at her own house. She was now 59. She had a high degree of exophthalmos with very wide palpebral fissure. She was in a state of extreme nervousness with much tremor. She was extremely thin. Her heart was rapid and irregular. The thyroid enlargement was moderate and general and the veins over it were enlarged and pulsating.

2. A woman at the age of 22 developed a swelling in her neck and her eyes became prominent. The swelling gradually increased, and she suffered from trembling and palpitation, and she attended the Brompton Hospital as an out-patient for some years. At the age of 42 there was still exophthalmos and slight enlargement of the thyroid, and there was much visible pulsation in the vessels of the neck.

3. A man at the age of 22 developed typical symptoms of exophthalmic goitre. Previous to onset he was fireman to locomotive engine. His illness never incapacitated him from work, and he had no treatment. At the age of 39 he had still some exophthalmos and thyroid enlargement. He died shortly after from acute diarrhoea.

On the other hand, we meet with cases which run a rapid course and terminate fatally in from six weeks to three months from the onset. Of this rapid course the following is an example.

Rapidly fatal case.—A married woman aged 31. On April 17th, 1916, she received a shock—the news of the death of her husband, killed at the front. She suffered from trembling and palpitation and dryness of the mouth and throat. She became very nervous, started at the least sound, and had a feeling of pins and needles all over. She was admitted to St. Thomas's Hospital a month later. There was marked tremor of the face and hands and rapid cardiac action, usually 120. She was very thin and weighed only 5 st. 8 lb. Exophthalmos was not obvious, and neither von Graefe's nor Stellwag's sign was present. There was no obvious enlargement of the thyroid gland at first, but later a slight swelling was evident. She lost 7 lb. more in weight in a month. Then she became drowsy. Sugar, acetone, and diacetic acid appeared in the urine, and she died on June 30th, two and a half months after the onset of her illness. At the post-mortem examination the thymus was found to be much enlarged, spreading downwards in a thick mass to the pericardium. Both lobes of the thyroid were enlarged. The right side of the heart was dilated.

There is reason to believe that in about 25 per cent. of the cases death results from the disease, and that under ordinary medical treatment in about 50 per cent. more or less complete recovery will eventually take place, while in the remainder the disease continues in a chronic form during life.

³ Bull. et Mem. Soc. Méd. d. Hôp. de Paris, 1914, xxx., No. 22.

⁴ Wien. klin. Wochenschr., xx., 1907, 782.

Most of the recoveries are met with among the slighter cases, and among the more severe cases it is certainly very rare to attain what can be admitted to be a complete recovery. Let us hope that improved methods of treatment will bring us better results among the more serious cases.

TREATMENT.

As I have said elsewhere, the natural course of the disease is so variable that there is great difficulty in correctly interpreting the effects of treatment. Under similar conditions as to treatment some cases improve rapidly, some remain stationary for a long time; others fluctuate or steadily lose ground and end fatally. I think I may safely say that I have made a trial of every known remedy. Of drugs, bromides are certainly useful where the nervous symptoms predominate. Belladonna seems to quiet the heart and soothe the nervous system. Opium is useful when there is looseness of the bowels. Phosphates and calcium salts seem to benefit when there is progressive loss of weight. I have tried all the organic preparations—thymus, pituitary, suprarenal, thyroid—separately and in combination, and have not found any special virtue in any of them. I am quite unable to endorse the eulogy of the late Dr. George Gibson³ as to the effects of suprarenal extract: "The rate of the pulse is reduced, the protrusion of the eyeballs disappears, the thyroid gland diminishes, the tremor along with every other nervous symptom vanishes, and the patient is restored to health in a way that we never see under any other method of treatment."

The attempts which have been made to obtain a useful remedy from the serum or milk of thyroidectomised sheep or goats have ended in failure. For a time, through the kindness of Mr. Walter Edmunds, I had an ample supply of milk from goats which had been deprived of their thyroid glands. No obvious benefit resulted from the treatment. The serum prepared by Merck and the substance called thyroid-ectin are quite inert. The powder called rodagen seemed to be beneficial when given in large doses in certain cases where wasting was a marked feature, but I think it is probable that casein would have had the same effect.

The general principles of treatment of the disease are well understood and agreed upon. But there are two important methods of treatment which are still *sub judice* and which, I think, specially require discussion at the present time. These are X ray treatment and operative treatment.

X RAY TREATMENT.

The effect of X ray exposures in reducing splenic enlargements, especially in cases of myelæmia, led one to hope that similar results might follow their application to the goitre of Graves's disease. It is many years since I first employed it, and its use has probably occurred to many independently. But although I have made use of it for many years and in many cases, it is only recently that I have had the most convincing evidence of the effectiveness of the treatment. I may say that I have gone on using the treatment not because I had met with any very striking success in my own practice, but because I was favourably impressed by the reports of benefit from X ray treatment published in the medical journals from time to time. I not only tried the effect of X ray exposures over the thyroid, but also over the thymus, and I was induced to try this because I was not satisfied with the results of X ray thyroid treatment. In 1909 I treated a number of cases in this way. Whether the treatment was employed over too short a time or not I do not know, but I obtained no very conclusive results at that time.

I shall give a few illustrative examples, showing sometimes improvement, at other times no obvious effect, and then I shall relate the most remarkable case which I have as yet met with.

1. A single woman aged 18 was treated in St. Thomas's Hospital from July, 1909, to February, 1910. It was a typical case and there was a six months' history. X ray treatment to the thyroid was started on August 20th, and she had applications of $\frac{1}{2}$ pastille through boiler-felt filter for 10 minutes twice a week until Oct. 2nd. On Nov. 20th X ray treatment over the thymus was commenced. She had applications twice a week for three weeks, then once a week for three weeks, and again twice a week for three weeks. On discharge her eyes were less prominent, the goitre was smaller, and she had increased a few pounds in weight, but her pulse was 104, the same as on admission.

2. A single woman, 18, telephone operator, admitted to hospital in June, 1906, and remained until February, 1907. There was a five months' history. She had lost a great deal of flesh, and weighed on admission only 4 st. 9½ lb., her height being 5 ft. 2 in. It was a typical case, with marked proptosis, considerable enlargement of the thyroid, and a pulse-rate of 120 to 128. During the first month she took very little food and occasionally vomited, and her weight fell to 4 st. 2 lb. She started X ray treatment on July 28th twice weekly, and her weight slowly increased until it reached 5 st. 6½ lb. in November and 6 st. 10 lb. in February, 1907. The goitre, however, gradually increased in size and the neck, which was 12 in. in circumference in June, was 13½ in. in November and 14½ in. in January. Although her nutrition and general condition much improved, her pulse-rate continued rapid—112. There is no record how many X ray applications were made, but they were numerous, and a very extensive freckling of the skin was produced. She was kept under observation during 1907, and during that time her pulse-rate was always quick—146 to 164. She was readmitted March 2nd, 1908, and her condition was much the same as when she left a year previously, except that her goitre had recently become larger, the neck measuring 15½ in., and the tremor was more marked. She was in the hospital for nine months, but there was no further improvement except gain in weight, her weight in November, 1908, being 7 st. 10 lb. In November, 1910, there was still considerable thyroid enlargement, the proptosis was still marked, there was a good deal of tremor, and the pulse-rate was 150.

3. A single woman, aged 25, milliner, came to St. Thomas's Hospital in August, 1908, with typical symptoms of Graves's disease of one month's duration. Under treatment she gained some weight, but the goitre increased in size and became very large, the pulse continued quick, 120 to 136, and the proptosis became more marked. In January, 1910, the exophthalmos became extreme and the right eyeball was twice dislocated but easily went back. In February, 1910, X ray treatment was started and was continued twice a week for over six months. At first her weight as well as the thyroid enlargement diminished, but at the end of September her weight had increased nearly 2 st. It was noted on Nov. 18th, 1910, that the patient's condition had much improved. She was able to be back at her business. No palpable enlargement of thyroid now. Proptosis decidedly less. Hands quite steady when held out. Pulse-rate 108, as compared with 120 at first.

4. A single woman, aged 32, was treated in St. Thomas's Hospital from February to June, 1910. There was a two years' history. On admission there was a high degree of exophthalmos. The pulse was 120. No enlargement of the thyroid was made out at this or at any other time. She lost a stone in weight during the first six weeks she was in the hospital, but subsequently regained it. She was treated with X rays over the thymus from March 16th to May 31st, and had 12 applications altogether. The most marked improvement was in the pulse-rate, which for the first six weeks was 100 to 120, but for ten days before discharge averaged 80.

In the following two cases of rapid progress X ray treatment appeared to be powerless to influence the march of the disease.

5. A woman, aged 19, was admitted in May this year with twelve months' history of exophthalmic goitre of gradual onset after some trouble or shock. It was a typical case, with considerable thyroid enlargement and the marked nervous symptoms. She received three X ray treatments at a week's interval. She, however, rapidly lost weight at the rate of 12 lb. in a fortnight. The tremor increased. She had to be hand-fed. Her mind wandered and she died from cardiac failure. A large thymus was found at the necropsy.

6. A young woman, aged 20, married, was admitted to hospital in September, 1916. About three months before she had some trouble and anxiety, but she was not really ill until about two weeks before her admission, when she felt nervous, depressed, and tired. There were slight exophthalmos, moderate thyroid enlargement, a pulse-rate of 120, and fine tremors of the hands. She had three X ray treatments in three weeks, but she rapidly lost weight to the extent of 19½ lb. Her pulse-rate in the fourth week became more rapid, her temperature rose, she rapidly became weaker, and she died four weeks after her admission. The chief feature of the post-mortem examination was the presence of a very large fleshy-looking thymus.

X RAYS CONVERT EXOPHTHALMIC GOITRE INTO MYXŒDEMA WHICH IS CURED BY THYROID TREATMENT.

The following case is of great importance and interest, showing as it does that a case of exophthalmic goitre can be converted by means of X rays into a case of myxœdema and then by means of thyroid treatment can be restored to a normal state. The total number of treatments in this case amounted to 36 and extended over a period of four years. It seems to me that a possible reason why X ray treatment

has not hitherto yielded better and more convincing results is that it has not been persevered with sufficiently long. In many cases the treatment has been given up after a comparatively short course because no very obvious improvement had taken place.

The patient, aged 23, came under treatment in March, 1912. For 18 months she had had enlargement of the thyroid and for 14 months exophthalmos. On admission to the hospital the thyroid gland was uniformly and considerably enlarged, the circumference of the neck being 14½ inches. There was a moderate degree of exophthalmos. The pulse-rate varied between 104 and 136. The blood pressure was 156 mm. and the blood picture was typical. There was well-marked tremor. She left at the end of June with general improvement. The enlargement of the thyroid was considerably diminished, the neck measuring 2½ inches less in circumference than it did on admission. She had one application of X rays in June before she left. After leaving the hospital she gained a stone in weight, but her thyroid enlarged again, and at the beginning of November her neck had increased 1½ inches. Her pulse-rate continued rapid, 120 to 140. In November and December, 1912, and in January and February, 1913, she had nine applications of X rays without any diminution in the size of the thyroid, which, if anything, got a little larger. Up to the beginning of February she was increasing in weight, and then she was 25 lb. more than when she left the hospital. During the next four months she lost weight steadily to the amount of 18 lb. She remained in about the same condition until March, 1914, but her general health was fairly good and she was able to be at her work. In March, 1914, she resumed X ray treatment, and I lost sight of her for a time. She then weighed 9 st. 12 lb. She had X ray treatment on the following dates during 1914: March 9th, 16th, 23rd; April 20th; May 11th, 18th, 25th; June 8th, 22nd, 29th; July 20th; August 10th, 24th; Sept. 7th; Oct. 19th; Nov. 16th, 30th; and Dec. 29th—18 applications in all. During 1915 she had treatment on Jan. 26th, March 23rd, April 29th, June 8th, July 6th, August 9th, Oct. 12th, and Nov. 9th—eight applications.

The patient returned to see me in March, 1916, with the typical appearance of myxœdema. She stated that she had been getting stouter for about six months. Her face had become puffy, her legs thick, and her hands large. She had felt the cold very much during the winter and her limbs were scarcely ever warm. Her hair was very dry and was coming out very much. Her voice was getting very thick and hoarse, and her speech was slow and monotonous. Her pulse was 80 and her weight was 10 st. 12 lb. No thyroid enlargement could be made out. She was put on thyroid tablets, 1 grain (representing 6 grains of gland) twice a day. In two months all signs of myxœdema had disappeared, and her weight was reduced to 9 st. 6 lb. She continued the thyroid tablets, and when seen in July, 1916, the only remaining sign of exophthalmic goitre was that the eyes were very slightly prominent, but neither Stellwag's nor von Graefe's sign was present. There was no thyroid enlargement. Her heart was going quietly at the rate of 72. She was doing her work as a general servant, and was quite equal for it. I saw her again on Oct. 24th, 1916, and her condition remained normal except that she had to continue the thyroid tablets. Her blood picture was then quite normal.

I have never before seen such a complete disappearance of the signs and symptoms of well-marked exophthalmic goitre as has taken place in the above case. I think one is justified in ascribing the cure to the prolonged X ray treatment.

Views on Treatment with X Rays.

My present views on X ray treatment are: It may prove to be far the best means of treatment at our command. It must be applied in no half-hearted way. It must be persevered with and in many cases continued for a long period of time. It is most likely to prove beneficial in cases where the thyroid enlargement is moderate and the patient is not so seriously ill as to necessitate confinement to bed. I think it may prove valuable in bringing about a retrogression of the remaining thyroid after a hemithyroidectomy. I have not at present sufficient evidence to speak of its usefulness where the goitre is a very large one. It has seemed to fail, as other remedies do, in cases of a severe type and rapid course. The trend of present experience in respect of X ray treatment is decidedly in favour of its further trial, and I would draw attention to a few recent important references to its effects.

Professor Halsted⁷ has recently been making trial of X ray treatment of the thymus which I have mentioned I employed seven years ago without any very striking results.

But Professor Halsted has used it in cases where he had previously removed most of the thyroid and the resulting improvement was not satisfactory. In these cases he thinks the X ray treatment has been very satisfactory.

Professor George Murray⁸ has stated that treatment with X rays has in some of his cases proved to be of great value. The gland gradually diminishes in size and the symptoms subside. These changes are, however, slow in development, so that the full effect of the treatment is not obtained until some months have elapsed. Fifteen to twenty weekly treatments have brought about great improvement or practical recovery in some cases. In others only slight improvement has followed similar treatment. He thinks it is worth while to persevere with X ray treatment for as long as 12 months if satisfactory progress is being made.

Dr. Florence Stoney⁹ has written enthusiastically of the effects of X ray treatment. Of 48 cases treated (of which 22 had no exophthalmos) 14 (of which 5 had no exophthalmos) were cured. The average number of treatments of the cases cured was 31, the smallest was 10, and the largest 50. She gives a small dose each time about seven to ten minutes. In acute cases she gives it twice a week for a month, then stops it for a fortnight. In chronic cases one treatment weekly suffices, but it must be continued in severe cases for six to eight months. Early cases are cured with a few treatments. Long treatment is only required where the case is very acute, where rest is unattainable, or where the case is of old standing.

Of the effects of radium treatment I have no personal experience to relate. Reports which have been published by D. Turner¹⁰ and others seem to show that they are very similar to those of X rays, and if this is confirmed radium treatment would be a valuable addition to our armamentarium. It is obvious that radium treatment might be employed in cases where X ray treatment was unobtainable.

SURGICAL TREATMENT.

Surgical methods of treatment of exophthalmic goitre have long been advocated and employed with the object of bringing about a more certain, a more lasting, and a speedier cure than can be obtained by other means. In the first cases in which partial thyroidectomy was performed the operation was done to relieve dyspnoea as in a case operated on by Lord Lister in 1877. It was found that not only was the dyspnoea relieved but all the symptoms were alleviated.

If the controlling and fundamental agent in keeping up the symptoms of the disease was the hyperplasia and over-activity of the thyroid gland, it seemed the most hopeful and rational means of treatment was to attempt to control that, and to the surgeon the use of the knife seemed the most natural method of dealing with it. He could cut away as much of the gland as was superfluous and leave the patient with just as much thyroid gland as was necessary for health. The theory seemed attractive; how did it work out in practice? Unfortunately, it was found that the operation had special dangers of its own, and while partial thyroidectomy in ordinary goitre was a comparatively safe operation, in exophthalmic cases it not infrequently proved fatal. The earlier statistics showed a death-rate of over 12 per cent. for the whole number, and among the severe cases it was as high as 22 per cent. Later statistics show better results, however.

My own experience of operation in cases of exophthalmic goitre has, on the whole, been very unfavourable. In several chronic cases in which the tumour was large partial thyroidectomy has been successfully carried out with relief to the patient, but although I have seen patients who have been benefited I have not seen any case that I could say was actually cured.

The risks attending thyroidectomy being considerable, surgeons have introduced modifications of the operation to diminish the danger. Ligature of the thyroid arteries was done as a preliminary in many cases, and according to Kocher it was found that ligature of one superior thyroid artery brought about a slight amelioration, which was increased by ligaturing both, and still more by ligaturing the inferior thyroid on one side in addition. So it came about that ligature of the arteries was frequently done as a preliminary to hemithyroidectomy and sometimes as a curative method in itself.

⁹ THE LANCET, 1913, vol. ii., p. 924.

¹⁰ Johns Hopkins Hosp. Bulletin, vol. xxvi., pp. 55-57.

If I now give a few details of my experience of the results of operative treatment at St. Thomas's Hospital during the last ten years, it will be understood why I have not hitherto been of opinion that it is the most promising or the safest means of treatment at our disposal. The first three cases were very discouraging.

1. In 1905 a woman aged 21, who had had symptoms of Graves's disease for two and a half years, was admitted under my care. She was a typical case. She remained some months in the hospital with little change in her general condition. Then it was decided to give her the chance of benefit by operation. Right hemithyroidectomy was performed under general anaesthesia. She stood the operation well, but she became restless and delirious and later comatose, and died 26 hours after the operation with great rapidity of pulse and respiration. A large thymus was found to be present.

2. In 1906 a girl aged 16, who had had symptoms of Graves's disease for three months and was not improving, was operated on. Right hemithyroidectomy was performed under general (ether) anaesthesia. The operation was difficult. The patient bore the anaesthetic badly, having two attacks of dyspnoea during its administration, and, like the other case, after the operation became delirious and collapsed, and died comatose after seven hours. No post-mortem examination was performed.

3. In 1908 a woman aged 43, with eight years' history of Graves's disease and with marked exophthalmic goitre and general excitability, was admitted to the hospital. Partial thyroidectomy was performed under general anaesthesia. She died eight days later with septic bronchopneumonia. The thymus was not recognised.

These three fatal cases in succession were not encouraging, but in 1909 two cases were operated on, one ligature of arteries, the other hemithyroidectomy, and both recovered. In 1910 7 patients were operated on with one death. Of these, 2 were cases of ligature only and 5 were thyroidectomies with or without ligature. The fatal case was a man aged 19, who for five months had had symptoms of Graves's disease, and these were typical on admission to the hospital. He was operated on after he had been in the hospital two months. He died under a general (C.E.) anaesthetic during thyroidectomy. No post-mortem examination was made.

In 1911 6 cases were operated on, all ligature of the superior thyroid arteries, and of these 3 proved fatal—two a few hours after the operation, the third after an interval of 14 days. In all these three cases there was a very large thymus, and the thyroid was also much enlarged. The ages of the patients were 18, 21, and 30.

In 1912 only one case was operated on, and that proved fatal. The case was that of a woman aged 29 with an 18 months' history. There was a high degree of exophthalmos and a moderate goitre. She was losing weight, 9 lb. being lost in the five weeks preceding operation. Both superior thyroids were ligatured, and the isthmus was excised under hedonal anaesthesia. She died the following day after tachycardia, pyrexia, and rapid respiration. There is no mention of thymus in the post-mortem report.

In 1913 6 cases were operated on, 1 ligature of arteries, which recovered, and 5 hemithyroidectomy, 2 of which proved fatal. Of the fatal cases 1 was a woman aged 33 with an eight months' history of Graves's disease. There was much restlessness and general nervousness. The goitre was a large one. The right lobe was removed under hedonal anaesthesia, and death ensued 10 hours after the operation. The thymus was found at the post-mortem examination to be much enlarged. The other fatal case was a woman aged 23 with 12 months' history, the symptoms coming on after fright. She improved under medical treatment and gained a stone in weight. There was marked exophthalmos and the thyroid was much enlarged. She died under anaesthesia. At the post-mortem examination the thymus was found to be enlarged, although repeated X ray examination had shown no sign of this.

In 1914 3 cases were operated on, 2 ligature of arteries, which recovered, and 1 left hemithyroidectomy, which proved fatal four hours after the operation. The fatal case was that of a woman aged 18. A persistent thymus was found at the post-mortem examination.

In 1915 3 cases were operated on—2 ligature of arteries which recovered and 1 hemithyroidectomy which proved fatal 10 hours after the operation. The fatal case was that of a woman, aged 35, with a three years' history. She never recovered consciousness after operation. At the necropsy no evidence of lymphatism was found.

In 1916 2 cases have been operated on, both hemithyroidectomy; 1 recovered and 1 died. The fatal case was a man, aged 29, with a history of an attack of exophthalmic goitre nine years previously, from which he practically recovered. There was a relapse three months before operation. He only survived the operation a few hours.

Summary of Results and Views on Operative Treatment.

To sum up the results of operations, in 15 cases ligature of the thyroid arteries was performed and of these 3 terminated fatally—2 a few hours after the operation and 1 after an interval of 14 days. In 3 of the 12 cases which recovered the symptoms were not typical and it is doubtful if these were true cases of Graves's disease. In 19 cases thyroidectomy was performed, of which 8 ended fatally. In 4 of the 11 which recovered there was no evidence of Graves's disease found on microscopical examination of the thyroids. In only 2 cases, and both of these cases of ligature of thyroids, was local anaesthesia employed. Of the cases which recovered from the operation no obvious change for better or worse was observed in 12 cases. In 2 cases of ligature of arteries general improvement was noted after the operation. In 2 cases after ligature the patient was worse, in one the thyroid increasing in size and the eyes becoming more prominent, and in the other the pulse being very irregular after the operation.

Our results at St. Thomas's, then, altogether are not at all encouraging. There has been a percentage of deaths amounting to 42 per cent. among the thyroidectomies and to 20 per cent. among the cases of ligature of arteries. It may be noted that the percentage of fatal cases was much higher among those under 25. For persons under the age of 25 the percentage of fatal cases was 53, while for those above the age of 25 it was 24.

Such being my experience among hospital patients, it is not surprising that I have not been an advocate of operation among my private patients. But of the latter a certain number have come under surgical treatment. Some of these have died, and I cannot say whether the others have been much the better for the operation.

A male patient aged 49, whom I saw with Dr. Barclay Baron of Clifton, had had symptoms of exophthalmic goitre for 12 months. It was a typical case, and there had been much loss of weight. Under medical treatment he improved and put on weight, but the goitre increased in size. Later on Dr. Baron took him to Berne, where Professor Kocher ligatured first one superior thyroid and then the other. He was to have had a hemithyroidectomy, but he died from pneumonia after the second operation.

Another case was a woman aged 28, who had had symptoms of Graves's disease for a few weeks when I first saw her. She improved very much under medical treatment, but after a time I lost sight of her. Recently I had a letter from the doctor who sent her to me, saying: "Some time after you saw her a well-known surgeon operated on Miss —, and she died next day."

It is difficult to understand why the results of operation at St. Thomas's Hospital should have been so unfavourable as a whole, while from reports published by many surgeons such a favourable impression of operation results is to be obtained.

Klose¹⁰ published in 1913 a table giving results of operations for exophthalmic goitre by various surgeons from 1896 to 1912. The percentage of cures or of considerable improvement ranges from 50 to 98.7, Th. Kocher claiming 93.7 per cent. and Mayo 97.8 per cent. The percentage of deaths allowed by Th. Kocher is 1.3 and by Mayo 2.2. These figures, I have no hesitation in saying, should be received with great reservation.

A more convincing report has recently been published by Judd and Pemberton.¹¹ Of 121 cases operated on in the Mayo Clinic in 1909, 55 were cured (24 by ligation alone), 22 were benefited but showed some slight evidence of the disease, 7 were markedly improved, 5 were only slightly improved, 8 showed little or no benefit, 21 died, 7 soon after the operation (all of hyperthyroidism). In this, the 97.8 per cent. of cures or considerable improvement has fallen to 70 per cent., but even that is, I am sure, much too high if the cases operated on are true cases of exophthalmic goitre.

In regard to this point I have read with much interest the pronouncement by Professor W. S. Halsted¹²

¹⁰ Klose: Die Basedowsche Krankheit, *Ergeb. d. Inn. Med. u. Kinderheilk.*, Band x., 1913.

¹¹ *Surg., Gynec., and Obstetr.*, March, 1916.

¹² *Harvey Lectures*, 1913-14, p. 245.

who says: "The results of my experience as regards the cure of Graves's disease by one-sided lobectomy are quite at variance with the views of other surgeons." According to this eminent surgeon, who has performed "perhaps 650 operations upon about 500 patients with Graves's disease," a one-sided lobectomy has resulted in an approximate cure in possibly 60 per cent. of the cases, but in certainly more than 60 per cent. (possibly 70 or 80 per cent.) there remain symptoms of over-activity of the thyroid or thymus, or of both of these glands, sufficiently pronounced to be detected by the expert clinician. This statement carries conviction with it, and is in perfect agreement with what I have seen of the results of hemithyroidectomy. In a later communication¹³ Professor Halsted refers to certain cases where even after a double lobe thyroidectomy the improvement had been so unsatisfactory that further treatment was necessary.

The frequent presence of an enlarged or persistent thymus in exophthalmic goitre suggested to Professor Garré, of Bonn, to attempt the cure by resecting the thymus gland. Those who are interested will find a full description in Professor Halsted's Harvey lecture already referred to. The case of von Haberer, in which after prolonged search he succeeded in extracting from behind the manubrium a piece of tissue 3 cm. long and $\frac{1}{2}$ cm. thick, which resembled fat and seemed to contain no thymus gland, and three months later the patient was perfectly well, seems to me rather an example of *post hoc* than one of *propter hoc*.

Local Anæsthesia.

The question of general *versus* local anæsthesia is a very important one, and I am strongly of opinion that operation under local anæsthesia is much safer than under a general anæsthetic. Thomas Huntingdon thinks "we cannot escape the conviction that general anæsthesia is in a very large proportion of cases seriously at fault," and Professor Kocher advocates local anæsthesia, maintaining that a general anæsthetic adds greatly to the danger. I have had no personal experience of operation under local anæsthesia until ten months ago. I then saw two cases operated on by Dr. Dunhill, of Melbourne, and I have since seen one case operated on by Mr. Cunning. In these three cases the operation of hemithyroidectomy was successfully carried out, and the patients have done well since. I should certainly advocate local anæsthesia in future, but recently it has not been possible to procure sufficient novocaine to carry out any further operations.

It may be useful to give the following case in some detail, as showing the actual results attained in one of the hemithyroidectomies under local anæsthesia.

A girl, aged 17½ years, was sent to see me in April, 1914, by Dr. Sutcliffe, of Margate, with a two years' history of exophthalmic goitre. She had a large goitre and extreme exophthalmos, which was very disfiguring. The heart was beating at 128 per minute and was obviously hypertrophied. She was the eldest of a family of four girls, the other three being all remarkably healthy. At the age of four she became affected with tubercle, and successively the fingers, arms, neck, face, head, feet, and legs were the seat of abscesses. She underwent 23 operations, but in the end made a good recovery, and when I saw her showed only the scars of the various incisions which had all soundly healed. She had lived off and on for the last eight or nine years at Margate and had latterly been at school, but had done little work to speak of. Naturally, having been through so many operations, she was very averse to any further surgical treatment. She had all the usual symptoms, especially those of the nervous system. She was excitable and impatient of restraint, and it was difficult to get her to keep quiet and take sufficient rest. Dr. Sutcliffe thought Margate did not suit her, and it was arranged that she should live at home near London and have medical treatment. At first she improved, gained in weight, and her heart became quieter, but the improvement was not maintained, and she not only lost the weight she had gained but an additional 9 lb. At the same time the goitre increased considerably in size. In December, 1915, she implored me to do something more to cure her. The goitre was large and locally inconvenient, and she was obviously getting worse. With my experience of the dangers of thyroidectomy in cases of this kind I felt a very serious responsibility before advising her to submit herself to operation. But thyroidectomy seemed the most likely treatment to benefit her. About this time I met Dr. Dunhill, of Melbourne, and asked him to see her with me, which he kindly did. Although not considering it to be one of the most favourable cases for operation, he

agreed it would be right to give the patient the chance. The operation of hemithyroidectomy was accordingly performed on Dec. 20th, 1915, under local anæsthesia. It was completely successful. The patient stood the operation very well. It was half over before she knew that it had begun, and she expressed pleasure immediately it was over that she had not to suffer any of the disagreeable after-effects of the anæsthetics of which she had had such a large previous experience. I saw her a few days ago and she is certainly now in much better health than she had been for 18 months before the operation. One of the most striking results has been the re-establishment of the catamenia, which had been absent for some eight months before operation and previously to that had been very irregular. One cannot, however, say that a cure has been effected. I can see no difference in the exophthalmos. The heart is still acting as rapidly as before, and when I examined her the rate was 144 to the minute. But she is less restless and excitable and the outlook is much more hopeful than it was before the operation. To effect a cure the remaining lobe of the thyroid must be reduced either by further operation or other means.

My views of operative treatment are:

1. If done at all operation should be performed under local anæsthesia. Local anæsthesia is specially indicated in younger subjects.
2. Ligation of the thyroid arteries does not appear to have any appreciable effect on the disease, and therefore, if done at all, it should only be as a forerunner of thyroidectomy.
3. Thyroidectomy does not cure unless a sufficient amount of gland is removed.
4. If possible, it is better to remove more than an entire lobe at one operation. I do not think the risk will be appreciably increased if this is done.
5. If a whole lobe is left behind it is probable that another operation will be necessary at a later time, unless by means of other treatment a sufficient reduction of the remaining lobe can be brought about.

ON A ROSE-IRRIGATOR FOR SUPPLYING A THERAPEUTIC FLUID CONTINUOUSLY AND AT A STANDARD TEMPERATURE TO THE WHOLE SURFACE OF A WOUND.

BY COLONEL SIR ALMROTH E. WRIGHT, C.B.,
M.D., F.R.S., A.M.S.,

THE LATE CAPTAIN H. H. TANNER, R.A.M.C.,

AND

DR. RALPH C. MATSON,

HONORARY LIEUTENANT, HARVARD UNIVERSITY HOSPITAL UNIT.

THE ordinary garden water-pot with a rose provides convenient apparatus for breaking up a large into a number of small streams for the irrigation of an extensive surface. But when a slow and continuous irrigation is required the device of the garden water-pot leaves us in the lurch. It has the defect that as soon as we cut down the supply the water is delivered, not, as one would wish, discontinuously in drops through all the apertures, but in a continuous stream through a single aperture. And then the water runs off in a single runnel.

The method of circumventing this difficulty has been explained in a previous communication¹ dealing with the employment of bandages for the irrigation of wound surfaces. It was pointed out there, in connexion with a stream of water carried in a bandage, that it can be divided up into as many branches as one likes by tearing the end of the bandage into tails. To apply this principle we introduce a strip of bandage into the spout of our water-pot and carry a strip to each orifice in the rose.

This is a first requirement for applying a system of irrigation to an extensive wound. For irregular hollow wounds—and wounds which are flat like a garden plot are exceptional—a further requirement is to modify the rose. For in a wound we may have to irrigate at one and the same time a vertical and a horizontal, or an upper and a lower face, or a tunnel or a number of pockets. To do this our irrigating

¹² Johns Hopkins Hospital Bulletin, vol. xxvi., pp. 55-57.

¹ Wright: THE LANCET, Oct. 16th, 1915.

fluid must be delivered from tubes carried forward from the face of our rose.

We fulfil this requirement by employing as our rose a perforated rubber cap, and inserting into the perforations (as was done by Carrel when he covered in his wounds with rubber sheeting, and drained off through this by suction) a set of tubes. To give stiffness to these rubber tubes, and carry them round corners, a copper wire is inserted into each. These were devices of our late colleague Captain H. H. Tanner.

Certain subsidiary improvements have here in the course of time suggested themselves. A drop counter has been introduced to tell whether the stream is flowing and to enable us to regulate the rate of flow. And the copper wires, which used to work loose and protrude, are now anchored to a rubber bung or piece of very stout drainage-tube or aluminium ring inserted into the barrel of the drop counter, or into the irrigating rose itself. (Figs. 1 and 5.) With this, so far as we can see, all the mechanical requirements of a good distributing system are satisfied, and we can now apply our therapeutic fluid over the entire surface of any wound.

Application of Different Patterns of the Irrigator to Different Types of Wounds.

The irrigator here in question may be made in different patterns to suit different requirements. In the one pattern—we call it *Mark 1* (Figs. 1, 2, and 3)—the drop-counter and rose with irrigating tubes make one piece. In the other—we call it *Mark 2* (Figs. 5 and 4)—the drop counter forms a separate element, and the irrigating rose is made as light as possible. The former pattern of irrigator is fitted up by attaching it to the splint by aluminium tape in the manner shown in the figure (Fig. 3), and where there are wounds on the posterior aspects of the limb the delivery tubes are taken round the limb and bent into position.

Where the limb is not anchored to a splint, and we have, as after amputation of a leg, to irrigate the vertical faces of a wound, we may with advantage employ the lighter pattern of irrigator, fitting it to an aluminium arm attached to a plate of perforated zinc which is bandaged down upon the limb. (Fig. 4.) With this arrangement there is no risk of the irrigation tubes becoming displaced.

Problem of Securing the Delivery of the Irrigating Fluid into the Wound at a Standard Temperature.

There yet remained another problem. It was the problem of supplying to the wound—and this, of course, is essential if it is to be treated upon physiological principles—a *therapeutic fluid*² maintained at such a temperature as will bring into full application the antibacterial powers of the organism. The optimum temperature for this purpose is, as experiments on emigration and phagocytosis carried out in emigration tubes teach, a temperature approximating to 40° C.

To achieve, in despite of varying external conditions, the delivery of fluid at a steady temperature of something above blood heat, a good many different factors have to be controlled. (a) The fluid in the reservoir must be kept constantly at the proper heat. (b) The loss of heat between the reservoir and the outlets of the irrigating tubes must be brought under proper control. And (c) the rate of flow must be so adjusted as just to cover the loss of heat and yet not flood out the wound.

(a) *Maintenance of the irrigating fluid in the reservoir at the proper heat.*—This is best achieved by the use of a thermos flask. A convenient way of fitting it up as an irrigating reservoir is shown in Fig. 6. For refilling the bung is removed, hot water is filled into the flask, and the temperature is adjusted by the aid of a thermometer.

(b) *Limitation of the escape of heat from the fluid when on passage from the reservoir to the outlets of the irrigating tubes.*—Experiment shows that there is an important and irregular

loss of heat when the fluid is conveyed to the irrigator through a long length of thin-walled tubing; that this evil is exaggerated with wide-bored tubing, for then fluid lies waiting for passage; and again that the evil is further increased when the regulating screw clamp is applied in the region of the reservoir instead of in the region of the irrigator, for then we have waiting in the tube a body of already cooled water instead of a body of hot water. And again experiment shows that there is an important and irregular loss of heat in the drop chamber when this is too large.

So that the following points must be attended to. The size of the drop counter chamber must be cut down. We must employ a thick-walled and narrow-bored rubber tubing, taking care that it is not too thick-walled or too narrow-bored to interfere with the delicate regulation of the flow of water by our screw clamp. And when our tubing has too thin walls or too wide a bore, we must cut down the length of the tube, and be careful to apply the clamp at its distal end.

We find that an almost absolutely accurate regulation can be obtained by employing a two-foot (i.e., $\frac{2}{3}$ metre) length of $\frac{3}{8}$ inch (9 mm.) external and $\frac{1}{8}$ inch (5 mm. internal diameter, and applying the screw-clamp about two or three inches above the irrigator.

(c) *Regulation of the rate of flow.*—This is done by the screw-clamp, timing the rate of dropping by the drop-counter. For accurate regulation it is, of course, essential to have drops of fixed size. We obtain these by regulating the external diameter of the dropper, the size of the drops being, of course, determined by the extent to which they cling round the outside of the tube. The standard size we have chosen for the dropper is one of 4 mm. external diameter, obtained by inserting the drawn-out glass tube into a hole in the perforated zinc which is supplied to hospitals, and filing and breaking off the point at the level where it is nipped by the aperture. In the case of a medium wound we may adjust the flow at 90 to 100 drops; in a larger wound at 110 to 120 drops; and in a still larger wound at 130 to 140 drops per minute.

The table below gives the temperatures at which the fluid in the reservoir (thermos flask) must be maintained to give, in connexion with the three rates of flow just specified, and the other conditions particularised above, delivery in the wound at a temperature of 39° to 40° C. (102° to 104° F.).

| Rate of flow in number of drops per minute. | Temperature which must be maintained in the reservoir to obtain delivery at 39° to 40° C. |
|---|---|
| 90 to 100 | 75° C. (167° F.) |
| 110 to 120 | 73° C. (163° F.) |
| 130 to 140 | 71° C. (160° F.) |

Method of satisfying oneself that the irrigator is in good working order and is delivering fluid at the proper temperature.—The essential points to look to are the following:

(a) We must see that the fluid is being delivered from the outlets of all the irrigating tubes. If this condition is not satisfied we must remove the rubber rose and see that a strip of bandage is inserted into the orifice of each tube. We must also, to prevent the tubes becoming blocked with grit, periodically see to the renewal of the gauze filter which lies upon the floor of the drop counter. (b) We must see that the arrangements for regulating the flow are functioning properly. It will be found in some cases that the walls of the tubing gradually yield to the pressure of the screw clamp, with the result that the rate of flow is gradually retarded. This condition can often be remedied by boiling the rubber tube. If this does not suffice, a wider-bored and thinner-walled tubing must be employed. (c) We must—for the wound surface is insensitive to temperature—see that the irrigation system delivers the fluid at the required temperature. We do this by collecting all the delivery tubes into an empty test-tube, kept warm by immersion in a bowl of water at blood heat, and explore the temperature with a clinical thermometer.

Method of carrying off the irrigation fluid from the wound, and preventing it leaking away into the bed.—The carrying off of the irrigation fluid and the keeping of the bed dry are not the very difficult things they have been supposed to be. Where the limb is lying horizontally, and a segment of the mattress has been taken out from under it, a broad strip of jaconet can be passed under the limb and the corners can be looped up and tied round the limb above and below the wound. A kind of hammock is thus formed. In combination with this strips of bandage are employed to drain the

² The italics here are intended to suggest to consideration that while the regulation of the temperature must in connexion with an irrigating fluid employed to incite physiological reactions be of dominating importance, such regulation need not therefore be imperative when we are irrigating only with a view to achieving antiseptic effects. And it may in this connexion be pointed out that it is doubtful whether physiological requirements in the matter of temperature could be conformed to when irrigating with hypochlorite antiseptics. For experiments—suggested to us by our fellow-worker, Major G. Dreyer—have shown that both eusol and Dakin's fluid very rapidly lose antiseptic potency when kept warm, even when kept at a temperature of blood heat.

FIG. 1.—Rose-irrigator, Mark 1, showing the drop-counter, gauze filter, and bung for anchoring the copper wires in position. The rubber cap has been dislodged to show the strips of bandage in its interior.

FIG. 2.—Rose-irrigator, Mark 1, showing the component parts. A, The perforated rubber bung into which the copper wires are inserted. B, The rubber cap everted to show the method in which the outlet tubes and the strips of bandage are inserted. C and D, The drop-counter and glass barrel.

FIG. 3.—Showing the irrigating rose, Mark 1, fitted to a splint and the arrangement of the outlet tubes and bandage siphon drains.

FIG. 4.—Showing the method of fitting the irrigating rose, Mark 2, to an amputated limb.

FIG. 5.—Irrigating rose, Mark 2. The rubber cap is dislodged to show the strips of bandage in its interior.

FIG. 6.—Thermos flask fitted up as an irrigating reservoir. A, Outlet for fluid; this is connected up with the rubber delivery tube. B, Inlet for air; this tube is carried up above the level of the fluid.

wound. In such a case as that shown in Fig. 3 the bandages function as siphons and pass down round the limb. In wounds in dependent positions the bandages would be employed as direct drains. And in either case they pass out through a hole cut out in the trough of the jaconet hammock and go down into a basin placed under the bed.

When the limb cannot be kept in the horizontal position, or where from the anatomical relations of the wound the jaconet hammock is inapplicable, we can, as explained in a previous communication,² bank back the fluid, and effectually prevent leakage into the bed by "irrigation flanges," built up of cotton-wool covered and fastened down to the skin by strips of bandage soaked in formalin gelatin.

THE BACTERIOLOGY OF THE FÆCES IN DIARRHŒA OF INFANTS.

By W. R. LOGAN, M.D., M.R.C.P. EDIN.,

TEMPORARY CAPTAIN, R.A.M.C.; CLINICAL PATHOLOGIST, ROYAL INFIRMARY, EDINBURGH.

(From the Research Laboratory of the Royal College of Physicians, Edinburgh.)

THE research on which this paper is based was carried out in the summer of 1912 and in the following winter. It was not intended to publish this portion till the work had been carried to a more complete issue. In the present unsettled state of affairs, however, it is considered advisable to use a leave of absence to prepare the following preliminary communication.

The method of study as suggested by Professor J. Ritchie, superintendent of the Research Laboratory of the Royal College of Physicians of Edinburgh, was to make as complete an examination as possible of the intestinal flora of healthy infants and of those suffering from diarrhœa, the differences between the two groups being likely to furnish data bearing on the etiology of infantile diarrhœa.

It was found that the flora of healthy infants varied widely according to the method of feeding, the flora of breast-fed infants differing from that of artificially fed.

In my first paper on these experiments (1914¹) the flora of 21 infants who were free from diarrhœa was dealt with. Eighteen specimens from 14 cases of diarrhœa were partly described. In that paper the scheme of routine examination was given in detail; the same scheme was applied to the cases described in the present paper. Briefly, the method consisted, on the microscopic side, of differentiating the organisms present by means of Gram-stained films. For cultures, from broth emulsions MacConkey plates for the recognition of lactose and non-lactose fermenters were prepared; ordinary agar plates were used for the coccal forms, and for anaerobic bacteria glucose broth, of ordinary reaction or acidified, and milk were employed. After the primary isolation was effected, the organisms obtained were subjected to various further tests. The characters of the "acid-tolerant" and "lactose-fermenting" groups of bacteria, the cocci and the spore-bearers, as isolated both from normal and diarrhœa cases, were fully gone into in the first paper. The conclusion was come to that these groups of organisms were not causal agents of infantile diarrhœa. The "non-lactose-fermenting" group of bacilli, on the other hand, so much more numerous in the fæces of diarrhœa cases, was left for description which is now given below.

The cases of diarrhœa were infants and young children who were patients at the Royal Hospital for Sick Children, Edinburgh. The majority were inmates of Charteris Ward, and I was able to study them through the kindness of Dr. J. S. Fowler. It is important to note that they occurred during the cold and wet summer of 1912, and in the autumn and winter following. Specimens were taken on one or more occasions from 14 cases. Table I. shows the main differences between the intestinal flora of healthy children and of those suffering from diarrhœa. The average findings of 21 normal children under the different diets (A, B, and C) are given at the foot of the table to facilitate comparison. As pointed out in the first paper, the acid-tolerant group greatly predominates over the others in the flora of breast-fed infants, the *B. coli* group and cocci being present in small numbers, while spore-bearers are unimportant. In children

on artificial diet the acid-tolerant group is somewhat reduced, the other groups are relatively increased, and members of the non-lactose-fermenting group begin to make their appearance.

The diarrhœa cases have been divided into three clinical groups.

Group I. contains 2 cases of very mild diarrhœa. Both were on diet C, which in their case meant "anything that was going." Comparing their intestinal flora group by group with that of healthy children on diet C one observes no important change from the normal. No bacilli of the non-lactose-fermenting group were isolated. These cases were evidently due to unsuitability of diet and scarcely come into the class of case which is the subject of this research.

Group II. includes 5 cases of fairly severe diarrhœa, not of dysenteric type. Four were on diet B, one on diet B plus a small amount of diet C. Comparing their flora with that of normal children on diet B striking differences are observed. In the diarrhœa cases there is (i.) an increase in numbers of the *B. coli* group, (ii.) a decrease in numbers of the acid-tolerant group, (iii.) a great increase in numbers of the non-lactose-fermenting group, (iv.) a slight increase in numbers of cocci, and (v.) no increase, possibly a decrease, in numbers of the spore-bearers. The cocci tended to grow in longer chains than in normal stools. This change is analogous to the tendency of diplococci to grow in chains in fluid media, and is probably secondary to the diarrhœa. The characters of the *B. coli* are given in Table X. of the previous paper, tests of their pathogenicity to guinea-pigs in Table XII.; the types were the same as those isolated from normal children, and their virulence to guinea-pigs was not exalted. Therefore, apart from the increase in numbers of the normal *B. coli*, the chief change in these diarrhœa cases is the presence in considerable numbers of members of the non-lactose-fermenting group, along with a decrease in numbers of the acid-tolerant group.

Group III. contains 7 cases of severe ileocolitis, which, clinically speaking, might be classed as dysenteries. The changes in this group are the same as those observed in Group II., but more marked. Again cocci were numerous, especially as cocci in chains, *B. coli* were normal in type and increased in numbers, spore-bearing bacilli very scanty or absent. For the character of members of these groups reference must again be made to the previous paper. The noteworthy change was a great increase of the non-lactose-fermenting group and a great decrease of the acid-tolerant group. In one case no members of the former group were isolated, but *B. proteus* was present in very large numbers. Cases XLII., XLIV., and XLVI. were fatal, and from the two latter were isolated unagglutinable strains of dysentery bacilli.

The changes from the normal in the flora of diarrhœa cases is an exaggeration of the changes seen in the stools of artificially fed infants as compared with those on the breast.

The non-lactose-fermenting group of bacilli.—Into this group fall all Gram-negative bacilli, morphologically of coliform type, which do not ferment lactose nor liquefy gelatin. The best-known members are *B. typhosus*, *B. paratyphosus* A and B, and the various types of *B. dysenteriae*.

In the summers of 1902 and 1903, a large number of workers in America, chiefly under the director of Flexner (1904²) at the Rockefeller Institute, examined the stools of a series of cases of epidemic infantile diarrhœa, with the object of determining the presence or absence of the dysentery bacillus. They were successful in isolating dysentery bacilli, chiefly of the Flexner-Harris type, in about 63 per cent. of the stools examined.

Between 1905 and 1908, Morgan (1906³), along with Ledingham (1909⁴), made extensive studies of the non-lactose-fermenting bacilli isolated from the stools of children in England suffering from epidemic summer diarrhœa. He found Morgan's No. 1 bacillus to be as prevalent in diarrhœa cases in England as the dysentery bacillus was in America—that is, in 63 per cent. of cases; that the sera of many of these cases agglutinated the bacillus, and that diarrhœa could be produced in monkeys by feeding them with this organism. He found also that other types of non-lactose fermenters were much more common in diarrhœa cases than in normal.

From 1910 onwards Lewis (1911,⁵ 1912,⁶ 1914⁷) in Birmingham has made a careful study of this group of

organisms. In the cold summer of 1910, in which the outbreak of summer diarrhœa was slight, he found non-lactose-fermenting bacilli in 77 per cent. of diarrhœa cases, and in 14 per cent. of normal; nearly half of these were Morgan's No. 1. In 1911, in which there was a serious outbreak of summer diarrhœa, he found non-lactose fermenters in the stools of 95 per cent. of children suffering from diarrhœa, and of 38 per cent. of children not suffering from diarrhœa. The great majority of these were of the type of Morgan's No. 1. He found this bacillus to be more pathogenic to mice by feeding than were the other members of the non-lactose-fermenting group; but that the strains of Morgan's No. 1 isolated from normal cases were fully as virulent as those isolated from cases of diarrhœa. He established by agglutination tests that Morgan's No. 1 bacillus was in reality a group of organisms. He proved that Morgan's No. 1 bacillus, isolated from normal children, from milk or from mice, may exhibit agglutination reactions identical with those of Morgan's No. 1 bacillus isolated from diarrhœa cases. In 1910 he found bacilli with the characters of the Flexner type 11 times in 47 cases of diarrhœa (23 per cent.). In the summer of 1911, in 175 specimens of fæces from 140 cases of diarrhœa, bacilli with the cultural characters of the dysentery group were isolated on 10 occasions only (7 per cent.).

In America, therefore, the type of non-lactose fermenter prevalent in cases of epidemic summer diarrhœa has been shown to be the dysentery group, while in England it is the gas-producing group known as Morgan's No. 1.

Table II. gives the reactions, &c., of the non-lactose-fermenting bacilli isolated from my series of specimens. In this table the fermentation of the sugars is given as read off at the end of one week's incubation; the change in milk as at the end of a fortnight's incubation; the indol reaction as at the end of a week's incubation in peptone water, Ehrlich's test being used. Motility was tested at the end of four to six hours' incubation in ordinary broth; the effect on gelatin was observed for three months at room temperature. Agglutination tests were done by the macroscopic

method, living cultures being used. The paratyphoid and dysentery sera came from Berlin, and were kindly given me by Dr. F. E. Reynolds. The Morgan's No. 1 serum was prepared from rabbits by increasing doses of killed cultures of strain XLIII 6.

All these cultures were put through the series of tests a second time at the end of three to six months' growth on artificial media. All organisms gave identical results at both testings, except organism XXXIX. 2, which at the first testing left dultite untouched, but at the second fermented it with gas production.

Organisms XLI. 10 and 11, which were liquefiers of gelatin, do not belong to this group of organisms, but are included for comparison.

Bacilli of the non-lactose-fermenting group were isolated from 6 out of 21 infants and young children who were free from diarrhœa (28.5 per cent.). Bacilli of this group were isolated from 11 out of 14 cases of diarrhœa, or 78.5 per cent. If one eliminates the two rather doubtful cases of diarrhœa, XVII. and XVIII., the percentage becomes 91.6.

The non-lactose-fermenters isolated may be divided for discussion into (1) the Morgan's No. 1 group; (2) the dysentery and "dysentery-like" group; and (3) the "paratyphoid-like" group.

Morgan's No. 1 bacillus was obtained from 2 out of a total of 21 normal children examined—that is, from 9 per cent. It was obtained from 5 of 14 children suffering from diarrhœa, or 35 per cent. Reference to the table will show that one of the strains isolated from a normal child was agglutinated by serum XLIII 6; the other was not. Strain XLIII. 6, as mentioned before, was derived from a case of diarrhœa. A strain isolated from another case of diarrhœa was also agglutinated by this serum as well as the homologous organism, while strains from three other diarrhœa cases were not. This is in accordance with Lewis's observations, already referred to, as to the occurrence of members of definite cross-agglutinating subgroups of Morgan's No. 1 bacillus in both normal and diarrhœa specimens. Further reference to the table will show that a Morgan's No. 1

bacillus from a diarrhoea case may be fatal to a guinea-pig, while another strain also from a diarrhoea case, and agglutinable by the same serum, may prove non-fatal in exactly the same dose. A large dose of a strain from a normal case was rapidly fatal to a guinea-pig. It will be noted that Morgan's No. 1 bacillus was isolated both from cases of diarrhoea, Group II., and from the severe type of ileo-colitis, Group III.

There was therefore an increase of the Morgan's No. 1 group in cases of diarrhoea, but identical members of the group, agglutinated up to titre by the same serum, were obtained both from diarrhoea cases and from a child who was at the time, had been, and continued to be, free from diarrhoea.

Dysentery and "dysentery-like" bacilli.—Bacilli classed as true dysentery bacilli, although inagglutinable by the stock Flexner and Y sera, were obtained from no healthy cases, but were found in 3, or 21 per cent., of diarrhoea cases. Two other bacilli, resembling dysentery bacilli in reactions, but motile, were isolated from diarrhoea cases.

Three strains of true dysentery bacilli were of the Flexner-Y type in cultural reactions. The children from whom they were obtained had truly dysenteric symptoms, and two of them died. The strains were all highly pathogenic to guinea-pigs. There is little question that these were cases of infantile bacillary dysentery analogous to the American cases referred to. These cases are described in more detail below.

The organisms isolated from Cases XX. and XXXIII. were in some respects akin to the dysentery group, but both were motile. Recently it has been claimed that a true dysentery may be produced by motile "dysentery-like" bacilli such as these, but further evidence is necessary.

The "paratyphoid-like" bacilli.—No true paratyphoid bacilli were isolated from any case, but "paratyphoid-like" bacilli were isolated from three cases free of diarrhoea, and one, XXXIX. 2, from a case during convalescence from diarrhoea.

The strains from normal cases resembled B. para. B in size of colonies on plates and in heaviness of growth on agar slopes, but in action on litmus milk resembled B. para. A. Two of them were non-motile in four hours old broth cultures, which is not uncommon with B. para. B, but in my experience very

G.-p. = guinea pig; — in all columns up to gelatin indicates that test gave a negative result; — in columns after gelatin indicates that test was not carried out; N.L. = non-liquefier; Sl.L. = slow liquefier.

rare with B. para. A. They were not agglutinated by paratyphoid or Gaertner sera, and showed a moderate degree of pathogenicity to guinea-pigs. The other strain, XXXIX. 2, was peculiar in not fermenting dultite at the first testing, but in having all the reactions of B. para. B or B. Gaertner at the second testing, five months later. In our examinations of Dardanelles troops at the M.E. laboratory under Captain Archibald, R.A.M.C. (1916*), one of our greatest difficulties was the distinction between true paratyphoid bacilli and harmless "paratyphoid-like" bacilli. Fifteen such inagglutinable strains were obtained by blood culture from cases of undoubted paratyphoid fever. In infants such organisms are in like manner a source of difficulty, but in the present series of cases appeared to be unconnected with the diarrhoea.

Other non-lactose-fermenting bacilli of Groups H and J (Lewis) were obtained from normal cases, while a bacillus of Group I. was obtained from a diarrhoea case.

Observations of a ward epidemic of diarrhoea.—The mode of incidence of the following six cases is of interest.

Case XLI. was admitted to a ward in the beginning of November, 1912. From a specimen examined on Nov. 3rd bacilli resembling Morgan's No. 1, save that they liquefied gelatin, were isolated.

Case XLII. had been admitted to this ward in September suffering from empyema (XXXI.). She was then free from diarrhoea, and a "paratyphoid-like" bacillus was isolated from the stool. On Nov. 16th she developed acute diarrhoea with blood and mucus. From a specimen Morgan's No. 1 bacillus was isolated. A highly agglutinating serum was prepared from strain XLIII. 6.

Case XLII. was admitted to the ward on Nov. 5th suffering from lobar pneumonia. On Nov. 18th she developed acute diarrhoea with blood and mucus in the stools. On Nov. 19th Morgan's No. 1 bacillus was obtained from a specimen. The child died on Nov. 23rd. The Morgan's No. 1 bacillus from this case was not agglutinated by serum XLIII. 6, and therefore did not belong to the same subgroup of the Morgan's No. 1 group.

Case XLIV. was admitted to the ward on Nov. 13th. On Nov. 19th very severe diarrhoea with passage of blood and mucus started. On Nov. 24th an inagglutinable dysentery bacillus of Flexner-Y type was isolated. The child died on Nov. 25th.

It will be observed that in these four cases, all in the ward at the same time, and three of them starting acute diarrhoea within a period of three days, the non-lactose-fermenters isolated were different in each case.

Another case (XXIX.) was admitted to the ward in October suffering from diarrhoea. On Oct. 15th Morgan's No. 1 bacillus was isolated from her faeces. On Oct. 30th she was convalescent, and a second examination at this date again produced Morgan's No. 1 bacillus, along with a "paratyphoid-like" bacillus (XXXIX.). In the latter part of November and in December she had another very severe bout of diarrhoea, but a specimen was not examined during this period. On Jan. 6th she had completely recovered and from her stool at this date (specimen XLV.) was isolated a dysentery bacillus, inagglutinable, with Flexner-Y reactions. This child was in the ward at the same time as Case XLIV., from whom a similar organism was isolated.

The last case of this series, XLVI., was admitted to the ward in December, suffering from chronic diarrhoea, along with an ischio-rectal abscess. Towards the end of December his diarrhoea became very acute and of dysenteric type. On Jan. 6th a dysentery bacillus, inagglutinable, with Flexner-Y reactions, was isolated from his stool. The child died on Jan. 9th.

It is reasonable to suppose that the cases from which specimens XLIV., XLV., and XLVI. were obtained were (1) infected one from the other, or (2) infected from a common source. When specimen XXXIX. was obtained from the second child her flora was still of the diarrhoea type and harboured Morgan's No. 1 bacillus, and was therefore probably less protected against the onslaught of a dysentery bacillus. That this child was still harbouring a dysentery bacillus after complete recovery from diarrhoea directs attention to the carrier problem in dysentery of infants as well as of adults.

The cases XLI. to XLIII. still remain a puzzle. They occurred in apparently epidemic form, and yet the non-lactose-fermenter isolated was different in each case. Is the explanation possibly that Cases XLI. to XLIII. were suffering from true dysenteric infection, but that the secondary overgrowth in the intestine of other non-lactose-fermenters had concealed the presence of the dysentery bacilli? Is it that there are several varieties of non-lactose-fermenters

which are capable of producing a diarrhoea or even an inflammation or ulceration of the intestine? Or does a common cause produce conditions in the intestine permitting the overgrowth of non-lactose-fermenters as a result rather than a cause of the diarrhoea? It is impossible without further research to answer these questions.

I would again lay stress on the differences between the flora of breast-fed children and of children on artificial diet, and on the exaggeration of the same differences when one proceeds further to the flora of children suffering from a diarrhoea. In my first paper it was pointed out how completely the acid-tolerant group is able to outgrow the non-lactose-fermenting group in a medium containing lactose or glucose, the acid produced by the splitting of the sugar rapidly killing off the latter group of organisms. It is possible that the acid-tolerant group plays a beneficial part in restricting the growth of these organisms, and that any cause, chemical or otherwise, which inhibited the growth of the acid-tolerant group might set up a diarrhoea by thus permitting an overgrowth of members of the non-lactose-fermenting group. Further work on these lines is desirable, and the relative immunity to diarrhoea of breast-fed children should be taken as a starting-point.

Summary.—Fourteen cases of diarrhoea were all on artificial diet at the time of onset. The flora of artificially fed infants differs from that of breast-fed infants chiefly in a decrease of the acid-tolerant group, an increase of the normal B. coli group, and in the appearance of members of the non-lactose-fermenting group along with some increase of cocci. The flora of infants suffering from diarrhoea shows similar but more marked changes, and the more severe the diarrhoea the more marked the changes. It is probable that the acid-tolerant group exerts a beneficial influence in restraining the growth in the intestine of the non-lactose-fermenting group.

Bacilli of the non-lactose-fermenting group were obtained from 6 out of 21 (28.5 per cent.) infants and young children who were free from diarrhoea. Bacilli of this group were isolated from 11 out of 14 cases of diarrhoea (78.5 per cent.). Bacilli of Morgan's No. 1 group were isolated from 9 per cent. of the normal children, and from 35 per cent. of the cases of diarrhoea.

True, though non-agglutinable, dysentery bacilli were isolated from none of the normal children, but were obtained from three cases of diarrhoea with blood and mucus (dysentery), or 21 per cent. of total diarrhoea cases. A certain number of cases of diarrhoea of infants are therefore true bacillary dysenteries, even in Scotland and in winter-time.

It is doubtful whether the overgrowth of non-lactose-fermenting bacilli initiates the diarrhoea, or whether it is a secondary and aggravating factor.

AN IMPROVED OPERATION FOR INTRINSIC MALIGNANT DISEASE OF THE LARYNX.

By H. LAMBERT LACK, M.D. LOND., F.R.C.S. ENG.,
SURGEON TO THE THROAT DEPARTMENT OF THE LONDON HOSPITAL.

In February last I demonstrated an improved operation for the removal of malignant growths of the vocal cords, and in April I described the method more fully in the *Journal of Laryngology*. The improvement consisted essentially in removing a portion of the laryngeal cartilages on the affected side. The steps of the operation are briefly as follows.

The larynx and the upper rings of the trachea are exposed through the usual vertical median incision and a tracheotomy tube is inserted. Then the soft tissues and perichondrium are turned off the thyroid cartilage on the affected side; the crico-thyroid membrane and the ring of the cricoid are laid bare. Next, if desired, thyrotomy is performed by splitting the thyroid cartilage in the median line in the usual way. By gentle traction on the margins of

the opening thus made the interior of the larynx can be inspected and the nature and extent of the growth seen. With strong cutting forceps the growth, with a sufficient margin of healthy tissue, is now cut away, together with the overlying cartilage in one piece. The taking away of the cartilage together with the underlying soft parts ensures not only a more thorough removal of the growth, but gives a much better view of the parts which are being divided, and much freer access for the use of instruments in the interior of the larynx.

The thyrotomy is not always necessary. When it is known that the growth is malignant and that it is limited to one vocal cord there is no need to split the thyroid. With a small saw the thyroid cartilage is divided in the median line from its lower edge upwards nearly to the upper margin. A transverse incision is then carried backwards just below the upper edge of the thyroid, nearly to the posterior border, and then downwards just in front of the posterior border. The square piece of cartilage thus marked out is removed, and subsequently the larynx is opened by dividing the underlying soft parts.

The following advantages were claimed for the operation.

1. It ensures more thorough removal of the disease by giving a free view of the parts to be removed, as well as by taking away the overlying cartilage.
2. The operation is rapid and easy.
3. Bleeding is easily controlled and the great danger of the operation—blood entering the air-passages and causing difficulty with the anæsthetic and subsequently septic pneumonia—is avoided.
4. After the operation the patient is able to swallow without difficulty or pain, which is not always the case with thyrotomy when there has been much wrenching apart of the cartilages.
5. Healing is rapid, and there is no subsequent necrosis of a fragment of cartilage, such as occasionally follows an ordinary thyrotomy.
6. The after-results as regards the voice are excellent and there seems no danger of subsequent laryngeal stenosis.

The advantages of this method, and more especially that of being able to see plainly the parts which are being divided and thus of being able to arrest immediately every bleeding point, have led me to simplify the operation. As all hæmorrhage can be immediately arrested the preliminary tracheotomy is obviously a useless and unnecessary complication. Being able to dispense with tracheotomy the usual vertical incision down the front of the neck can be replaced by a curved transverse incision. The advantages of the transverse incision, both with regard to rapidity of healing and the subsequent cosmetic effect, need hardly be mentioned. The transverse incision gives a better view of the parts to be removed and heals with hardly any scarring or puckering. Also, it is more superficial and less extensive, and the deeper tissues in the lower part of the neck are not opened up. Thus there is less risk of sepsis, and healing is more rapid.

This operation I recently carried out in the case of a feeble man, aged 72, with epithelioma of the right vocal cord. The man was suffering from general atheroma and cardiac degeneration, as well as from chronic emphysema and bronchitis. He was therefore a bad subject for a prolonged anæsthetic and especially for an operation upon the air-passages. It was essential that the operation should be performed quickly, that no blood or fluid should enter the windpipe during the operation, and that there should be no trouble in swallowing subsequently. Naturally also the smaller and the more superficial the wound and the quicker the healing, the more likely he was to survive. Under chloroform anæsthesia a curved horizontal incision was carried across the front of the larynx at the level of the crico-thyroid membrane. The tissues being divided down to the larynx the crico-thyroid membrane, the upper edge of the cricoid ring, and the right half of the thyroid cartilage were freely exposed. With a small saw the thyroid cartilage was divided in the median line from its lower edge nearly to the notch in its upper border. A cut almost at right angles to this was carried backwards just below the upper edge of the thyroid cartilage, and then another vertical incision was made near the posterior edge of the cartilage, so as to mark out a square of cartilage and leaving intact both the posterior and upper borders of the thyroid. The piece of cartilage thus

marked out was detached from the soft parts underlying it with a blunt dissector and removed. All bleeding being arrested the interior of the larynx was carefully opened in the median line through the crico-thyroid membrane and upwards along the course of the first incision in the cartilage above described. Then an incision was carried backwards along the lower border of the crico-thyroid membrane as close to the cricoid ring as possible, and the edges of the triangular flap thus marked out being retracted the interior of the larynx and the growth could plainly be seen. The growth, with a sufficient margin of surrounding healthy tissue, was now detached on a third side by a horizontal incision carried well above it, and finally dissected posteriorly off the arytenoid cartilage. All this cutting was carried out piece by piece and every bleeding point being picked up at once, the growth was removed without a drop of blood entering the air-passages. The operation up to this point occupied barely 35 minutes. Some time was now spent in allowing the wound to become "glazed" by exposure to the air and letting the patient come almost out of the anæsthetic, so that no possible source of subsequent bleeding should be left. When the wound was quite dry the edges of the skin were brought together by two stitches, except for a small gap at its centre which was left open for drainage. A simple dressing was applied and the patient returned to bed. He made an uninterrupted recovery without any complications. He was in a very feeble condition, and I feel sure that he could not have stood a severe operation or even a prolonged anæsthetic.

This operation is both safer and more thorough than the ordinary thyrotomy. It is safer because (1) it is simpler and therefore more rapidly performed; (2) it allows free access to the field of operation and therefore complete facility for dealing with hæmorrhage; (3) the smaller and more superficial wound entails less danger of sepsis; (4) the transverse incision heals more quickly; and (5) tracheotomy is quite unnecessary and is therefore omitted. It is more thorough because (1) it allows a good view of the parts to be removed; and (2) the overlying cartilage is also removed. These advantages are obtained without any corresponding risks or disadvantages. I believe, therefore, that it will be the method of choice in the future, and that thyrotomy, except as a purely exploratory operation, will no longer be practised.

Devonshire-place, W.

THE ORIGIN AND PREVENTION OF CEREBRO-SPINAL FEVER.

BY HALLIDAY SUTHERLAND, M.D. EDIN.,

TEMPORARY SURGEON, ROYAL NAVY; CONSULTING TUBERCULOSIS OFFICER FOR NORTH MARYLEBONE, LONDON; AND MEDICAL OFFICER TO THE ST. MARYLEBONE TUBERCULOSIS DISPENSARY.

IT may be that if the causes and prevention of cerebro-spinal fever had been less simple they would have been more generally accepted by the profession to-day.

The Specific Organism.

The diplococcus intracellularis meningitidis of Weichselbaum conforms to Koch's law for pathogenic organisms. Constantly found in the tissues and body fluids of the victims of epidemic cerebro-spinal meningitis, the meningococcus may be isolated in pure culture, is able to reproduce the disease in monkeys, can be recovered from the lesions in these animals, and is therefore the causal organism of cerebro-spinal fever.

Apart from the monkey, man is the only animal in whose nervous system specific lesions are produced by this organism. Starting, then, with the proved proposition that the meningococcus is the sole cause of cerebro-spinal fever, it is possible to show, with the exactness of a problem in Euclid, the means whereby man is infected, the conditions under which he develops the malady, and the method of preventing both infection and disease.

Conditions Determining the Spread of Infection.

At times when the disease is not prevalent meningococci have been found in the throats of 2 per cent. of healthy soldiers.¹ Among healthy naval ratings, not known to have

¹ Brit. Med. Jour., 1915, vol. 1., p. 466.

been exposed to infection, I found meningococci in the throats of two individuals out of a hundred examined. The organism has recently been found in a larger proportion of the civil population not exposed to infection.²

It is evident that meningococci may exist as harmless saprophytes in the throats of healthy persons. These people may or may not develop the disease, and they may or may not spread the infection to others. If they do transmit the meningococcus to other people, it is obvious that the number of persons amongst whom the disease may arise will be increased. The conditions which determine whether or not infection is spread are as follows. Any organism in the naso-pharynx may be expelled from the mouth during the act of coughing in small droplets of secretion which float in the air for from half an hour to four hours, according to the density and humidity of the atmosphere. This would easily explain the method of infection provided the temperature of the air was above 22° C., but on the other hand, meningococci so n perish at lower temperatures. Now 22° C. corresponds to 71.6° F., and I found that meningococci die in 30 minutes when exposed to a temperature of 60° F., while lower temperatures are more rapidly fatal.³ It is therefore clear that air-borne meningococcal infection can only occur in a warm atmosphere, and is impossible in cold air.

Epidemics of cerebro-spinal fever usually begin in January or February, and disappear with the advent of May. But January and February are the two coldest months of the year, as is proved by daily readings for many years of the temperature in the watermains at Chelsea. The temperature of water follows the mean air temperature, and in these months the lowest readings of 37° to 40° F. are obtained.⁴ The paradox of a disease which appears during cold weather, but whose specific cause is destroyed by cold air and can only be carried by warm air, is explained by the fact that cold wet weather leads to shutting off the natural means of ventilation, and that the air indoors becomes warm and saturated. Under these conditions air-borne meningococcal infection is carried from one person to another. Overcrowding was long regarded as predisposing to the malady, but in my original communication⁵ I showed that warm saturated air is the *actual cause* not only of the spread of infection but also of the incidence of the disease. An objection to this theory might be raised in the query, Why does not infection spread in the summer months when the air is warm? The air in summer is less saturated than in winter, droplets of secretion are dried up more rapidly, and meningococci offer no resistance to drying. Lastly, even if infection were spread in summer, the essential condition which determines the secondary invasion of the tissues would be absent.

Epidemics of cerebro-spinal fever have occurred among native races in tropical countries, and this is in favour of my explanation. In the West African jungle I found natives in ill-ventilated huts where the atmosphere at night must have been as saturated and warm from the breathing bodies of the occupants as the moist air from the swamps outside. In such a climate the only factor that would limit the spread of infection is the burning sun by day.

Conditions which Determine Secondary Invasion of the Tissues.

When warm saturated air is inhaled the nasal mucosa becomes swollen, congested, and covered with thick secretion, the activity of the ciliated cells is reduced, and phagocytic action in the lymphoid tissues is diminished.⁶ This means a lowered local resistance to any bacterial infection which may be present in the naso-pharynx. Now bacteria are only saprophytic by virtue of the superior resistance of the tissues, and if the resistance be lowered the bacteria become pathogenic. Warm saturated air enables meningococci to be carried to the naso-pharynx, creates there a local condition favourable to the growth of the parasite, and reduces the phagocytic properties of the lymphoid tissue, so that the organism is able to pass the first line of defence, enter the lymphatic system, and find its way *via* the

blood stream to the central nervous system, on which either cold or over-fatigue have acted as predisposing influences. Furthermore, warm saturated air favours the incidence of all air-borne infections. Thus on Feb. 5th, 1916, between the hours of midnight and 2 A.M., and between 4 A.M. and 5 A.M., I visited barrack-rooms in which over 2000 men were sleeping. One example of the conditions which prevailed will suffice. Room E3 was occupied by 16 men, which allowed 670 cubic feet per man. Of 12 windows only one was slightly open at the top. The air was hot, close, nauseating, and oppressive, while the moisture of condensation was streaming down the windows. I contend that the amount of cubic space per man is not a safe guide to the efficiency or deficiency of ventilation, which must be judged on common-sense data.

Now the case incidence of certain respiratory diseases due to air-borne infection in the above barracks was as follows for the six weeks ending Feb. 5th, 1916:—

| Week ending— | Catarrh. | Tonsillitis. | Sore throat. | Total strength. | Case incidence. |
|---------------|----------|--------------|--------------|-----------------|-----------------|
| Jan. 1st ... | 14 | 2 | 0 | 2112 | 7.5 per 1000. |
| Jan. 8th ... | 5 | 3 | 0 | 2067 | 3.8 |
| Jan. 15th ... | 6 | 0 | 7 | 2091 | 6.2 |
| Jan. 22nd ... | 23 | 2 | 3 | 2125 | 13.1 |
| Jan. 29th ... | 18 | 6 | 4 | 2128 | 13.1 |
| Feb. 5th ... | 60 | 10 | 10 | 2155 | 37.1 |

The rise in diseases due to air-borne infection is very apparent during the last week, and in that week two cases of cerebro-spinal fever appeared.

Prevention.

Once cerebro-spinal fever has appeared in any community, bacteriological examination of the contacts discovers the number of infected persons. These are regarded as potential causes of the disease, and the development of the malady among such people can sometimes, but not always,⁷ be prevented by the local application of antiseptic sprays or vapours to their throats. This treatment, if efficient, also prevents the further spread of infection, but of necessity it has a very limited application. It is no more practicable to free the throats of the entire population from meningococci than it would be to attack the widespread distribution of the pneumococcus as a saprophyte in the throats of healthy people.

To control the spread of infection once it has arisen is wise, but it would be infinitely wiser to prevent the possibility of infection in the first instance. The means of prevention are simple. All windows must be open day and night, and to prevent the necessity for closing them in rain or in wind, a weather-board of 18 inches in depth is fixed inside the lower part of the window at an angle of 45°, so that the lower sash may be screwed up one foot from the bottom. A night patrol may be required to see that the space between the window and the weather-board is not covered over with clothes to keep out the air. In the barracks to which I have referred these alterations were carried out at a cost of £200. No further cases of cerebro-spinal fever appeared, and the incidence of respiratory diseases showed a remarkable fall. These simple measures soon save their cost in preventing the possibility either of infection or disease, in obviating the necessity for an enormous amount of expert bacteriological work, in diminishing the incidence of all affections of the respiratory system, and in raising the general health of those to whom they are applied.

If these statements are tested on a large scale by the authorities during the coming winter there will be no cases of cerebro-spinal fever in the Services. There would be nothing very remarkable in such a fortunate result, for the power whose aid is here invoked is the *Vis Medicatrix Naturæ*.

Temporary Lieutenant-Colonel H. R. Kenwood, R.A.M.C., professor of hygiene and public health in the University of London, will deliver a public lecture at University College, London, on "Hygiene: Some Lessons of the War," on Friday next, Nov. 17th, at 5.30 P.M. The chair will be taken by Surgeon-General Sir Alfred Keogh, Director-General, Army Medical Service. The lecture is open to the public without fee or ticket.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OPHTHALMOLOGY.

Inaugural Address.—Exhibition of Cases.—Photography of Macroscopic and Microscopic Eye Specimens.—Bilateral Glioma of the Retina.—Recurrent Glioma of the Retina.

A MEETING of this section was held on Nov. 1st, Mr. WILLIAM LANG, the President, being in the chair.

In his inaugural address, the PRESIDENT advocated the appointment of a small committee to initiate and organise research and, perhaps, a bureau for collecting particulars of rare cases. In this way a quantity of valuable material would be available for research scholars, or for a committee appointed to make use of it. Further, a card-index system for the recording of all literature bearing on the science of ophthalmology in the United Kingdom would be very valuable. At present pathological confirmation of the findings of clinical observation on an adequate scale was lacking, especially in regard to septic foci as the cause of many eye diseases. With the society's excellent laboratory it only needed a system of subsidised workers. This could well be the occasion for joining with other bodies in a crusade to instruct the nation in the cultivation of right habits, notably in regard to clean mouths. The same purpose pervaded all: to decrease by British effort the power of every disease.

Mr. G. WINFIELD ROLL showed a case of Congenital Pigmentation of the Optic Disc. The patient was the subject of glycosuria, and the right eye was affected with retinitis. The vessels in the remainder of the fundus were normal.

Dr. F. E. BATTEN showed a child with Pigmented Degeneration of the Retina associated with epileptic fits. The sight had failed somewhat rapidly during the last year, and a central scotoma in both eyes had been demonstrated, somewhat to the temporal side. There was also optic atrophy and some pigmentary disturbance at or near the macula. Physical examination of the nervous system was negative. The father was syphilitic, but this patient showed no trace of that disease.—The case was discussed by Mr. PATON, Mr. R. D. BATTEN, Captain A. W. ORMOND, Mr. MAYOU, Mr. HERBERT PARSONS, and the PRESIDENT.

Mr. NORMAN B. B. FLEMING showed a case of Retinitis Circinata, with changes in blood-vessels.

Mr. A. C. HUDSON exhibited a new small Speculum.

Lieutenant-Colonel R. H. ELLIOT and Mrs. ELLIOT communicated a paper on the Photography of Macroscopic and Microscopic Eye Specimens. The object of the paper was to help those who desired to photograph macroscopic eye preparations, there being no available literature on the subject. The following points were regarded as of importance: 1. The photograph must be taken in water, without the intervention of glass or other similar material. 2. The source of light must be good and even. 3. The camera must be placed vertically above the object so as to avoid reflections. 4. The object of the photograph must be so placed that its image will occupy the centre of the plate, and a method of adjustment should be available to secure this end with a minimum of inconvenience. 5. A simple arrangement is necessary to fix the eye in position during the whole period of exposure. 6. To save unnecessary retouching the object should be photographed lying on a dark and uniform surface to obviate the background disturbing the attention of those viewing the picture. 7. Care should be exercised in the choice of a camera and exposure periods must be carefully studied. For the making of lantern-slides the contact method was recommended, and attention was directed to the following points: correct exposure; the preparation of plates for exposure; development and fixation of the slides; the drying of the plates; and the reduction, intensification, and varnishing of slides.

Dr. FRANK E. TAYLOR and Mr. FLEMING contributed a paper on a case of Bilateral Glioma of the Retina with Multiple Metastases. The patient was a female child aged 3 years, in whom an abnormality was noticed in the left eye 18 months previously. On admission to hospital there was a fungating growth protruding between the lids of the left eye, keeping them separate. The mass was bathed with a

thin, semi-purulent discharge. The right eye was much enlarged, and apparently proptosed, the iris fully dilated, and stretched into a thin band at the limbus, the lens being in contact with the posterior aspect of the cornea. The growth was of lemon colour. No reflex was obtainable ophthalmoscopically. Mr. Elmore W. Brewerton (with whose permission the case was recorded) operated at once, performing exenteration of the orbit, with partial removal of the lids, afterwards suturing the wound. The right eye was very freely excised. The optic nerve was found to be involved, being surrounded by growth for half an inch behind the eye. A fortnight after discharge from hospital there was a recurrence, half the size of a tennis ball, from which the patient died. She had shown but little evidence of suffering pain. Microscopically the growths were found to be composed of closely-packed small round cells, with large deeply-staining nuclei. A few spindle cells were also present. The body was much emaciated, and the metastases were extensively distributed. The subject was discussed from a general standpoint.

Mr. ARNOLD LAWSON read notes on a case of Recurrent Glioma of the Retina. The patient was a boy aged 3½ years, and the gliomatous eye was removed. It had almost perforated the globe. Mr. R. A. Greeves found a large scleral staphyloma at the front, and it was infiltrated with glioma cells, while masses of growth could be traced along the sheath of the foramen. After the patient had remained well for six months there was a recurrence in the orbital cellular tissues, and evisceration was carried out at hospital. There was a further recurrence, and 90 mgm. of radium were applied for four and a half hours. Free sloughing followed, and the child was kept in hospital for six and a half weeks, at the end of which time there seemed to be no sign of growth. Three months later, however, the patient was readmitted on account of a fluctuating swelling; it yielded pus, at the bottom of which was suspicious pultaceous material. Investigation revealed an extensive recurrence, beyond the reach of either further operation or radium. The child appeared to have a remarkable absence of pain, and seemed fairly comfortable except towards the end.—This paper and the preceding one were discussed by Mr. W. C. ROCKLIFFE, Mr. BREWERTON, Mr. PARSONS, Mr. HOLMES SPICER, Lieut.-Colonel ELLIOT, and Mr. TREACHER COLLINS, the last named calling attention to the different methods of spread of glioma and sarcoma of the orbit: one began in the neural epiblast and the other in the mesoblastic tissue. Sarcoma of the choroid generally spread by metastases, whereas gliomatous growths spread by continuity, and death occurred from local recurrences, as was shown in a number of cases traced by Mr. J. B. Lawford and himself. Lieut.-Colonel Elliot agreed with Mr. Brewerton's operative procedures, speaking from his experience of a number of such cases in India.

HARVEIAN SOCIETY OF LONDON.—A meeting of this society was held on Nov. 2nd, Dr. Edmund Cautley, the President, being in the chair.—A paper entitled "Warfare on the Brain" was read by Dr. E. Farquhar Buzzard, dealing chiefly with the subjects of shell shock and, secondly, traumatic epilepsy. Dr. Buzzard said that shell shock, a much-abused and unfortunate term, covered (a) cases of pure exhaustion; (b) cases in which exhaustion had excited inherited neuropathic and psychopathic tendencies into activity; (c) "martial misfits" passing as normal individuals in civil life but unable to bear the strain of military service; (d) normal individuals affected by close shell explosion and showing symptoms similar to those following a blow on the head. Care must be taken to exclude the presence of organic changes in the skull or brain; such a symptom as mutism is hysterical and signifies mental disorder and not a localised cerebral injury. In the first three groups direct exposure to shell explosion might be absent, he said, or at most was merely a culminating factor in the production of symptoms. The principle underlying surgical interference was, Dr. Buzzard said, not to cure the epilepsy but to restore the injured part of the brain as far as possible towards the normal; where operation would have the opposite effect it was contra-indicated. The treatment of the epilepsy itself was medical, and the prophylactic use of bromide in cases of head injury of great importance. The problem of the treatment of the large numbers of these cases occurring at the present time would, he said, be of national importance.—An interesting discussion followed Dr. Buzzard's paper.

Reviews and Notices of Books.

Les Formes Anormales du Tétanos.

Par M. COURTOIS-SUFFIT, Médecin des Hôpitaux de Paris, et R. GIROUX, Interne Pr. des Hôpitaux de Paris. Préface du Professeur FERNAND-WIDAL. Paris: Masson et Cie. 1916. Pp. 174.

THIS is one of a series of books connected with the war. It deals with the vastly important subject of tetanus, which was so greatly in evidence in the earlier stages of the war in Flanders and the north of France; but it does not concern itself with the typical and ordinary cases of the disease which naturally form the large majority of those seen, treating rather of the abnormal forms, which are more numerous than most surgeons think. The forms of tetanus to which the authors specially apply the term atypical are mainly those in which the disease is confined to the head, and those in which only a localised affection of the limbs occurs. Of the cephalic form there are several varieties according to the parts involved, such as those in which the eye muscles are affected and those where the hypoglossal is paralysed. In the partial forms of tetanus affecting the limbs we find cases where the disease is monoplegic and others in which it is paraplegic; and others again in which the muscles affected are only those of the thorax and abdomen.

Professor Vidal, who contributes a brief preface to this monograph, writes thus on the subject of local tetanus, and the passage is of sufficient importance to quote at length:—

Partial tetanus of the limbs offers not merely the interest of a clinical novelty; its special mechanism gives it a general bearing on the production of tetanus, an aspect which the authors rightly emphasise. In the same way as an attenuated typhoid fever is now and then met with in subjects insufficiently vaccinated, so tetanus may remain localised to the injured limb when sero-therapy has been practised under conditions which render it insufficient. It is a tetanus of incomplete immunisation and affords a good example of the modified morbid types with which preventive medicine is enriching the natural history of infectious diseases.

The authors have made a wide examination of medical literature as the extensive bibliography shows, and this monograph on the little-known varieties of a disease not commonly seen in civil practice is timely and valuable. The sections on prophylaxis and treatment are good, and it is hardly necessary to say that the authors insist on the prophylactic injection of antitetanic serum as the only trustworthy method of prevention.

LIBRARY TABLE.

Anatomy, Descriptive and Applied. By HENRY GRAY, F.R.S. Edited by ROBERT HOWDEN, M.A., D.Sc. Durh., M.B., C.M. Edin., Professor of Anatomy in the University of Durham. Notes on Applied Anatomy revised by A. J. JEX-BLAKE, M.A., M.D. Oxon., F.R.C.P. Lond., Senior Assistant Physician to St. George's Hospital; and W. FEDDE FEDDEN, M.B., M.S. Lond., F.R.C.S. Eng., Surgeon and Lecturer on Surgery, St. George's Hospital. Nineteenth edition. With 1143 illustrations, of which 499 are coloured. London: Longmans, Green, and Co. 1916. Pp. xvi. 1304. Price 32s. net.—This (nineteenth) edition continues to maintain all the best traditions of "Gray's Anatomy"—a work which is familiar to English-speaking medical men all the world over. We notice that the number of coloured illustrations has been increased, and that some 80 figures are new. A considerable number (about 60) of the older illustrations have been done away with and replaced by drawings which are the work of Mr. S. A. Sewell. The text has been revised throughout, but the general arrangement of the book is similar to that of the last edition.

The Essentials of Chemical Physiology for the Use of Students. By W. D. HALLIBURTON, M.D. Lond., LL.D., F.R.S. Ninth edition. With coloured plate. London: Longmans, Green, and Co. 1916. Pp. 324. Price 6s. net.—This eminently practical book has reached its ninth edition which

speaks well for its reception. It is rightly a great favourite with the student. Worthy of notice amongst the new matter are Ruhemann's discovery of the ninhydrin reaction for amino-acids, the urease method for estimating urea, the volumetric process for estimating sulphates, and the picric acid colorimetric method of Lewis and Benedict for estimating the sugar in the blood. This latest edition is a worthy successor of previous ones; the general outlines, a very difficult subject, are clearly stated and presented in a sequence which the student in the physiological laboratory will appreciate.

Authentic Dreams of Peter Blobs, M.D. Dunelm, and of Certain of his Relatives; Told by Himself, with the Assistance of Mrs. Blobs. London: Longmans, Green, and Co. 1916. Pp. 42. Price 1s. net.—Although this little book is published pseudonymously, it is not difficult from internal evidence to identify the writer. It is written with the praiseworthy object of assisting the funds of the Prisoners of War Help Committee, 5 and 7, Southampton-street, Strand. Of the dreams related the two first are the most striking, but what is chiefly notable in all of them is that they are free from the inconsequence which is so marked a feature of the dreams of most of us, an admirable example of which in literature is the dream in Kipling's "Brushwood Boy." The little book is cheap, it is quite worth reading, and any profits will go towards a worthy object. Therefore we hope it will have a large sale.

JOURNALS.

The Philippine Journal of Tropical Medicine, Vol. XI., No. 1.—To this number of the *Journal* Dr. E. R. Ruediger, of the Bureau of Science, Manila, contributes an article in which he describes some experiments he made with the view of finding some chemical agent which would render serum sterile and keep it so, without interfering with the tests to be applied to it. It is well known to serologists that when human serum is sent from a distance for the Wassermann reaction, it sometimes arrives in an utterly unfit condition for the examination; occasionally it is even putrid. Dr. Ruediger experimented with phenol, lysol, tricresol, and chloroform, all of which were soon abandoned as unsuitable. A more prolonged trial was made of formalin and glycerine, but it was found that the former was not suitable for the preservation of human serum intended for the Wassermann test. Sera which gave moderately positive results before the addition of formalin yielded negative, or nearly negative, results after this agent had been added. Glycerine, however, kept the serum sterile and did not noticeably influence the Wassermann reaction, nor the Tschernogubow modification of it. A second article is also supplied by Dr. Ruediger to this number of the *Journal* and deals with the subject of Hæmolysis by Human Serum.—Dr. Maria Paz Mendoza-Guazon, of the Department of Pathology and Bacteriology, University of the Philippines, describes an interesting case, with three illustrations in the text, of infestation of a child aged 8 months with a comparatively rare species of tapeworm in the human subject, the *Dipylidium caninum*, which is parasitic in dogs and cats and other carnivorous animals. The author, as regards prophylaxis, recommends the exclusion of domestic dogs and cats from opportunities of coming in contact with young children, especially those playing on the floor, and the taking of measures to prevent infants from putting their fingers in the mouth after touching dogs or cats.—The last article in this number is furnished jointly by Dr. Daniel de la Paz and Dr. Faustino Garcia, of the Departments of Physiology and Pharmacology, University of the Philippines. It is an experimental study of the use of apomorphine for the purpose of aiding the removal of foreign bodies from the respiratory passages, particularly from the trachea. This method is still mentioned in some standard text-books on pharmacology, the claim being that, as the result of the administration of apomorphine, coincidently with the act of vomiting, violent movements are produced which expel, or at least facilitate the expulsion of, the foreign body from the respiratory tract. Experiments to test this claim were carried out on dogs, but the authors were led to the conclusion that the use of apomorphine does not facilitate the removal of foreign bodies from the trachea.

Reports and Analytical Records

FROM
THE LANCET LABORATORY.

ZOEL ANTISEPTIC.

(AGENCY: G. LYNCH, WHITEHALL HOUSE, 29-30, CHARING CROSS, S.W.)

AMONGST boron compounds little attention appears to have been given to the monoborates, which bear a relation to diborates—e.g., borax—similar to that which carbonate of soda bears to bicarbonate of soda. The basic borate would, however, appear to possess valuable and distinctive antiseptic and deodorant properties which do not belong to the diborate or the free acid. We have recently had submitted to us a fluid preparation of monoborate of soda which, according to recent observations, has given most encouraging results in the treatment of wounds and in general antiseptic use. Some emphasis is laid upon the fact that it is alkaline which might imply irritating qualities. But this does not appear to be the case, while, of course, on account of its alkalinity it permits a free flow of lymph without causing it to coagulate or form incrustations. We have received some practical testimony on these points from hospitals where this monoborate fluid has been used in cases of wounds. The coagulating properties of an acid antiseptic would give preference to the use of an alkaline antiseptic so long as it is free from irritating properties, and that appears to be a favourable feature of the monoborate, which is besides a deodorant. The collaboration of an alkaline condition with an antiseptic means also that at the same time a detergent and cleanser is being used, encouraging the healing process. This development of the monoborates for antiseptic use, either in the form of potassium or sodium salt, is due to Mr. Charles Billing. The solution is quite stable and can be used if required warm. The hypochlorites, of course, are not stable under these conditions. There seems to be an interesting and important future in antiseptic work for the monoborates prepared in this way. Both a fluid and a dry salt are made.

BUTYL NITRITE.

(EVERITT AND CO., LIMITED, SOUTHALE, MIDDLESEX.)

We cannot trace any reference to the use of normal butyl nitrite in the same way that amyl nitrite has been employed in therapeutics, but the suggestion is of interest that the butyl nitrite might have advantages over its higher homologue and other nitrites which, as is well known, dilate the vessels and lower the blood pressure. The specimen submitted to us was a pale yellow oil which showed a boiling-point of about 68° C. It is, of course, somewhat more volatile than amyl nitrite and vaporises more easily, and a few seconds' inhalation causes the face to be flushed and a distinct effect on the pulse is accordingly produced. The preparation claims some attention as it may prove to have advantages over amyl nitrite derived from an alcohol of higher molecular weight. Toxicity decreases with reduction in molecular weight in many cases.

"KEPLER" COD-LIVER OIL WITH MALT EXTRACT AND CREOSOTE.

(BURROUGHS, WELLCOME, AND CO., SNOW HILL BUILDINGS, LONDON, E.C.)

This preparation represents the highly nutritive and digestive qualities of a malt extract prepared on scientific lines, of a refined cod-liver oil, and, lastly, of creosote, which possesses antifermentative properties. The combination is known to be of value in the treatment of phthisis, and it has the advantage of possessing an attractive flavour rather than a disagreeable one. In those cases in which it is desirable to help the nutritive needs of the patient—in wasting diseases generally—this preparation is, no doubt, of service.

BRITISH-MADE LANOLIN B.P.

(LONDON PHARMACEUTICAL REFINERS, LIMITED, MARTIN'S YARD, ENDWELL-ROAD, BROCKLEY, S.E.)

We have carefully examined this specimen of lanolin and we find that it answers all the requirements of the British Pharmacopœia. According to our examination it contained only 0.14 per cent. of moisture and 0.08 per cent. of mineral matter. These results are a long way below the limits set

out in the official demand. Further, we found that its acidity in terms of oleic acid was only 0.42 per cent., against a presumable limit of 0.7 per cent. It has been pointed out that in the test for acidity in the British Pharmacopœia it is recommended to make a solution in ether of 0.2 gramme for titration with N/10 alkali which would place the limit of free (oleic) acid at 7 per cent. It is an obvious slip; a solution should be made of 2 grammes and then the limit becomes 0.7 per cent. This matter is of some importance, as any increase in the amount of free fatty acid in lanolin is opposed to its value as a basis in many directions.

New Inventions.

A NEW BANDAGE FOR AMPUTATION STUMPS.

THE object of this bandage is to keep dressings on the stump after amputations in the lower limb; slight modifications of it will serve the same purpose in the case of the upper limb. Four pieces of domette or flannel are used; the width should be about 4 in. The exact measurements will vary with the patient. The band *a* in Fig. 1 should go round the waist above the iliac crests; and *b* and *c* round the stump. It will be found better for *b* and *c*

FIG. 1.

to be nearer the lower end of the stump, as shown in Fig. 2. The band *d* should pass down the back of the thigh, then be brought round the bottom of the stump,

and fixed anteriorly by means of safety-pins (as shown in Fig. 2 at *e'* and *e''*), and finally to the waist-band at *e*. The junction of the bands *a* and *d* can be made with safety-pins or, better, by sewing

with cotton. In the case of a stump below the knee or the elbow the band *a* will, of course, be made smaller and go round the parts above the joint. In the application of this bandage (3 inches wide) to the upper limb above the elbow-joint the point *e* should be about the middle of the band *a*, which should be crossed over the shoulder in a figure of eight and fixed with a safety-pin round the neck. Point *e'* will be rather near to *e*; the band *d* should be brought down the inner side of the arm round the stump, and fixed with safety-pins on the outer side of the arm to the bands *a* and *b*. A 3-inch roller bandage should be first applied to approximate dressings to the stump, and then the bandage described above applied over it.

FIG. 2.

W. S. RICHARDSON,
Captain, R.A.M.C. (T.).

AN IMPROVED SUTURE FORCEPS.

THE improvement in the suture forceps as shown by the illustration consists in curving Moynihan's forceps on the edge, thus removing the obstruction to the line of sight.

The advantage is at once appreciated when the instrument is in use. It is now obtainable from Messrs. Allen and Hanburys, Limited, Wigmore-street, London, W.

Orpington, Kent.

E. W. DIVER, M.D. Durh.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 11, 1916.

The Financial Interests of Medical Men on Service.

For the medical man it is always "business as usual," for whatever the circumstances or the environment there remains the same twofold task—he has to prevent disease and to remedy it. At the outbreak of war the words "business as usual" became a catch-phrase with writers and speakers. It was used to imply in the briefest form the greatness of this country, its powers of resource, and its equable temperament; and there is no doubt that in this way it became a sufficiently mischievous text, doing appreciable harm to our military efficiency in the preliminary stages of the conflict. For those who preached from the catch-phrase fostered a spirit under which things were taken too easily; thus recruiting was restricted, and the men who hung back thought their behaviour justified, and thereby lost many months of valuable training. It is true that the words soon ceased to be used, when their mischievous teaching was perceived; but the effect of this teaching remained and lay behind the opposition to compulsory military service.

Quite properly the words "business as usual" can be applied to the course which medical men should pursue now as always. The medical profession continues during the war to do that business of preventing and remedying disease and injuries which it was called upon to do before the war. The circumstances in which we work have altered only in appearance, for is it not true that the thousands of medical practitioners who are now with the colours are there because it is there that the disease and the injuries of a large proportion of our male population are to be found? But the fact remains that the more fragile section of the population stays behind, and on the medical men who remain to care for them there falls the grave responsibility of increased work with no commensurate increase of income. Complaints have reached the Central Medical War Committee that some practitioners are not recognising as fully as they should do their moral obligations to professional brethren who have undertaken military service. The Committee in expressing the opinion that these obligations should be cheerfully and generously discharged, as a privilege as well as a duty, are speaking for all the profession, and it must be remembered that the members of the Committee have exceptional facilities for knowing the problems that have arisen out of the existing dislocation of civil practice. Many medical men have made and are making very great sacrifices for their country, and the Central Medical War Committee suggest that thoughtlessness usually accounts for the fact that some of those who

remain at home are profiting unduly by their neighbours' patriotism. There is, however, much evidence to show that the private practices of many men on active service have almost disappeared. This is mainly because practitioners do not take the trouble to ascertain whether new patients were or were not in the habit of consulting doctors now on active service, and the Committee have devised a procedure which, if carried out, will minimise the loss which must in any case fall on those who leave their practices for any considerable period. In so doing, and not for the first time, the Committee are rendering service to the medical profession of a practical kind. They supply medical men with a scheme under which they can watch over the interests of brother practitioners on military service in the most convenient way, and they deprive indolent men of any excuse for taking no heed to the existing position, and for drawing profits from their want of thought.

We publish on p. 844 of the present issue of THE LANCET the procedure which the Central Medical War Committee propose might be followed, with suitable variations in different areas, for safeguarding the practices of medical men on active service, and we trust that all who are concerned will give the suggestions the closest possible attention. The regulations have been very carefully drawn up and an anxious attempt has been made to cover, under one or other of 13 headings, the main defects that are likely to arise where a medical man has gone on active service and left his practice to be managed for him by his professional colleagues. We would draw special attention to the regulation dealing with a vacancy which occurs from the death of a practitioner on service. Our columns are recording only too frequently these tragedies, and the honour of the profession is especially involved in seeing that any surviving relatives of the deceased officer shall benefit by the sale of his practice. The number of medical men who have already been killed while on active service is so large as to make it right that definite arrangements should be made in all areas to deal with a possible event. The needs of medical practitioners who have suffered financially through naval or military service must be taken under serious consideration by their brethren.

Local Tetanus.

THE control of tetanus by the prophylactic injection of antitoxin will justly rank as one of the triumphs of preventive medicine in the present war. Few wounded men now escape the injection, and the disease has become relatively rare in spite of the abundant infection which must still occur. But although tetanus has been scotched it has not been killed; cases are still occurring, though in small numbers. There is strong experimental evidence, as the recent revised Memorandum issued by the War Office Committee for the Study of Tetanus shows, that in about ten days the immunity conferred by the primary injection of antitoxin is to a great extent lost. Sir DAVID BRUCE, 12 months ago, concluded, upon an analysis of 231 cases of

tetanus treated in home military hospitals, that a prophylactic dose of antitetanic serum was at that time rarely given.¹ Now it is seen that a single dose may be insufficient. It is desirable, therefore, to draw attention to a result of the preventive administration of serum—namely, the occasional occurrence of the disease in spite of a prophylactic injection but modified by the latter to such a degree that it may become difficult of recognition. For some time past cases have been noted, in this and other countries, in which persistent spastic rigidity of a wounded limb has set in, lasting for weeks or even months, and occasionally ending in permanent contracture. Trismus may be quite absent in these cases and the condition has been so unlike the usual clinical picture of tetanus that the diagnosis has remained in doubt. Last November we published notes of three such cases by Lieutenant-Colonel R. D. RUDOLF and notes of another case by Mr. R. ATKINSON STONEY; our Paris correspondent in our issue of Feb. 19th called attention to the occurrence of somewhat analogous cases of "late tetanus"; other similar instances have since been recorded, and it is probable that they are occurring wherever the prophylactic injection of antitoxin is systematically practised. It is now clear that these cases of local spastic rigidity in wounded limbs are modified tetanus. There are two good reasons for this belief. The first is that in some of them the more ordinary symptoms of tetanus are later added to the local spasm; trismus, for instance, may supervene after some days or weeks, while in most cases, if not in all, careful examination detects some of the nervous manifestations of tetanus beyond the limits of the part primarily affected. The second reason lies in the identity of the condition with that which may be produced experimentally with tetanus toxin in animals. In the cat, an animal relatively insusceptible to tetanus, a sub-fatal dose of toxin produces a highly persistent tonic spasm of the limb injected, and nothing else. The same is true of the guinea-pig if the dose of toxin is accompanied or shortly followed by a sufficient dose of antitoxin. The man, like the guinea-pig, seems to be reduced by the dose of antitoxin to the level of insusceptibility naturally occupied by the cat.

The subject has recently been illuminated by Dr. MONTAIS in the July number of the *Annales de l'Institut Pasteur*, as well as by Dr. COURTOIS-SUFFIT and Dr. R. GIROUX in a monograph of which a review appears in another column. Dr. MONTAIS has collected from French sources alone no less than 21 cases of purely local tetanus, without trismus, as well as a number of similar cases in which trismus and other general symptoms later supervened. All were in persons who had received a prophylactic injection of serum. Although the form of tetanus which begins locally and is followed by trismus has long been known, pure local tetanus is a pathological novelty in man. Dr. MONTAIS states that the first case was recorded in 1913. The condition, he claims, is the creation of preventive serotherapy; tetanus tends to assume

this form the more frequently the shorter the interval between its onset and the prophylactic dose of serum. The influence of the serum gradually fades and Dr. MONTAIS distinguishes four degrees of modification according to the respective predominance of local or general symptoms. With the increasing involvement of the higher centres the mortality rises; contrary to the rule in ordinary tetanus, the prognosis becomes worse the later the disease arises in the protected man. Dr. MONTAIS's first group is that in which the tetanus remains limited to the region of the wound, or at the most shows some extension to the centres at the same spinal level: the pontine and bulbar centres escape altogether. It is this form which alone deserves the name of strictly local tetanus, and he finds it almost confined to the first month after the prophylactic injection. Sometimes the incubation period was only a few days, but in one case it was three months. Only two of his 21 cases died. In his second group, more frequent than the first, the tetanus is still local in its onset, but the protection of the higher centres is no longer complete, and after an interval of days or weeks, trismus and other general symptoms appear as a secondary phenomenon, often of no great severity: the disease is still in the main local. Such cases, says Dr. MONTAIS, may occur at any time during the first two months after the preventive injection, and the mortality is somewhat higher than in the first group. In the third and fourth groups, rarely seen within the first month, but apt to occur from the second month onwards, the protection of the higher centres is much less complete. The first obvious manifestations of the disease are trismus, cervical rigidity, and other well-known signs of general tetanus; a local onset in the wounded limb is no longer seen or at least no longer attracts attention. In the third group, although the protective action of the serum is largely exhausted, some residue of immunity still modifies the severity of the attack; the course of the disease may be slow and characterised by persistent spasticity rather than by severe crises. The mortality is here much higher—according to BAZY from 33 to 50 per cent. In the fourth group the tetanus is of ordinary type, all protection having vanished.

It is plain that this classification is an arbitrary one, and that the groups shade into one another, nor can the dates of occurrence of the different types be more than a general indication, since, as Dr. MONTAIS himself admits, the rate at which protection fades is a variable one. The tetanus bacillus is implanted in wounds usually, if not always, in the form of spores, and these may germinate and give rise to the vegetative organism, with its production of toxin, at any time up to many months after implantation, or they may never germinate at all. They are very difficult of destruction, and the wound may heal, leaving them still intact. The reawakening of such dormant spores is the cause of late tetanus, and this may occur long after the effect of prophylaxis has faded. The question arises why early tetanus in the protected man should assume the local form, and the

¹ THE LANCET, Oct. 23rd, 1915, p. 901.

answer seems as follows. It is generally held, since the work of MEYER and RANSOM, that the motor neurons are accessible to tetanus toxin only at their peripheral terminations in the muscles; the central nervous system is thus attacked up the motor nerves. The main route from a wound is hence obvious, and there is no difficulty in understanding the early involvement of those spinal centres corresponding to the site of the wound. Simple local tetanus is, however, practically unknown in the unprotected man; as a rule the centres in the pons and medulla suffer earliest, probably because in man they are the most susceptible. The route to these centres, except where the seat of infection lies within the realm of the cranial nerves, is a roundabout one through the blood-stream. In the protected man the antitoxin is circulating in the blood, and has therefore a far better chance of shielding the higher centres than the spinal ones directly accessible from the wound. The early case of local tetanus is, as Dr. MONTAIS urges, one in which the production of toxin is early and copious; but in the protected man, instead of a rapidly fatal issue, we see the violence of the attack spent upon the lower spinal centres because the higher ones are shielded. The mortality is low because the prognosis depends largely upon whether or not the higher centres are attacked. The gradual fading of protection, as time goes on, explains the reappearance of trismus and other general symptoms, till in the later stages the disease again runs its usual course. The combination of circumstances which leads to local tetanus is an uncommon one, but the explanation outlined above seems to be satisfactory.

With regard to the treatment of local tetanus, it would appear that the condition tends to be chronic, and that it is not readily affected by the administration of antitoxin. Dr. MONTAIS suggests that, since the fact that the tetanus is local proves the higher centres to be shielded, it will suffice to keep up the existing protection by the subcutaneous exhibition of serum. He quotes GOVAERTS, however, as affirming that the intrathecal route is particularly useful in this form of tetanus. There may not be the same urgency for the administration of antitoxin by the intrathecal route as exists in general tetanus, but this route would still appear to offer the best means of overcoming the local form of the disease. The first authorities in all countries advise that, to prevent tetanus in the wounded soldier, the protection given by the primary prophylactic dose of serum should be reinforced by its repetition at weekly intervals so long as the condition of the wound demands it. The War Office Memorandum, already mentioned, recommends this course in cases of long-continued septic wounds, particularly those caused by shell or bomb, and adds that the danger of anaphylactic shock, which may have deterred surgeons from this practice, is negligible when prophylactic doses of 500 U.S.A. units contained in 3 c.c. of horse serum are given subcutaneously, whatever the interval after the preceding injection. Even if the disease cannot thus be wholly prevented, the recorded cases of its conversion into the local form show that it may sometimes be robbed of its worst terrors.

Annotations.

"No quid nimis."

SALT IN THE DIETARY.

THE decision contained in an Army Order issued recently to reduce the ration of salt from half an ounce to a quarter of an ounce brings to the front the whole question of the rôle of salt in the dietary. The Order undoubtedly allows for the actual daily requirements of the body, since this has been calculated to be not more than an intake of 2 grammes, while a quarter of an ounce amounts to a little over 7 grammes. Few of us are concerned to think that by taking salt with food we are keeping up a saline equilibrium; we only value it for its salinity and in practice as a condiment, and its dietetic importance probably rests on the fact that it makes so many foods palatable. The foods which furnish salt are generally the animal foods, for sodium chloride forms a comparatively small percentage of the salts present in the cereals, tubers, and pulses. These contain chiefly potassium salts. Few foods, however, possess a natural salinity of their own; the oyster may be mentioned as an exception. The daily food ingested provides sufficient sodium salts for the body needs, yet such food is not salt to the taste, and this consideration would seem to confine added salt to the category of a condiment. Its action as a condiment deserves, however, further study, because the development of flavour which the addition of salt induces is undoubtedly due to increased osmotic action. In other words, the addition of salt conspires to produce an isotonic fluid with more rapid travelling activities, stimulating salivary flow and subsequently the secretion of the gastric fluid. The evidence, therefore, is in favour of the use of salt, not because there is a shortage of this in a mixed diet, but because it increases the palatability of food and likely enough its absorption value. The Army Order allowance seems small, particularly if the ration should include a preponderance of unsalted vegetable ingredients, but, on the whole, salt is extravagantly and wastefully employed.

A NEW METHOD OF STERILISATION AGAINST PEDICULI.

Professor Alfonso Muto, director of field hospital No. 59 of the Italian Army, has devised a simple and effective method of sterilising the soldiers' clothes as a prophylactic measure against exanthematous typhus.¹ He claims that in a 10 per cent. solution of creoline we have a substance which has the advantages of not being inflammable nor harmful to human beings, nor having a disagreeable odour. It does not damage the texture of the clothes or affect their colour, but, on the other hand, protects them against moth. It is easily obtainable, cheap, and destroys the parasites and their eggs in a very short space of time. The only apparatus required consists of a collapsible wardrobe, light and easily transportable, having a boiler of about 18 litres capacity which is connected by a pipe to the interior and can be heated over an ordinary wood fire. The clothes are hung up in the wardrobe and the creoline solution boiled; the clothes are withdrawn after another quarter of an hour, when they will be found to be hardly damp. Moreover, Professor Muto has observed that small needle-shaped

¹ *Annali d' Igiene*, August 31st.

crystals of naphthalin are deposited on the surface of the articles, which have an active and beneficial prophylactic action, since they prevent for a considerable period any fresh invasion of the parasite. This method is said to have overcome many of the difficulties met with in organising an antipedicular prophylaxis among troops on active service. That the soldier must remain stripped during the whole time occupied in disinfecting his clothes is an objection which has its palliating circumstances, since the interval may be utilised in applying some antiparasitic inunction in a tent.

THE "COMPLUETIC REACTION" (WASSERMANN) IN 100 CASES OF AMENTIA.

A USEFUL and suggestive investigation of the causative factors of idiocy and imbecility has been conducted by Mr. H. F. Stephens, and his results are incorporated in a paper recently read before the Psychiatry Section of the Royal Society of Medicine. His material consisted of 100 cases of amentia, of which 76 were cases of primary amentia and 24 of secondary amentia. Included in these groups were 11 cases of mongolianism, 4 of cretinism, 7 of amentia with paralysis (hemiplegia, &c.), 17 of amentia with recurring convulsions, and 3 of amentia with hydrocephalus. The inquiry was conducted with reference more particularly to the presence or absence of the Wassermann reaction as indicative of syphilitic activity. The mere fact that the great majority of the patients examined came under institutional discipline and observation at a very early age is sufficient to exclude the likelihood of any direct acquisition of that disease, apart from the absence of all the physical signs and symptoms of acquired syphilis at any period of their lives, so that where the Wassermann reaction was present the patients may be declared to be the victims of intra-uterine or congenital syphilis. Of the 100 cases, no fewer than 42 gave a positive reaction of varying strength. Mr. Stephens has told at considerable length the exact technique followed and the controls adopted, whereby the trustworthiness of his findings was thoroughly tested. It is interesting to note that in none of the positive cases were any of the accepted signs of congenital syphilis discovered, a fact which has been remarked by other workers in the same field. In view of the obvious truth that not all children of syphilitic parents are aments, the question arises whether the manifestations of congenital syphilis bear any relation to the time of onset of the infection *in utero*. According to Mr. Stephens, the majority of congenital syphilitics bear evidence of epiblastic or mesoblastic infection, which suggests a comparatively late intra-uterine onset, whereas amentia—i.e., such amentia as is here described—associated with a positive Wassermann reaction in the blood, is, broadly speaking, equivalent to arrest of brain development, and suggests a very early embryonic infection. A further matter of some interest is the determination of the part played by the syphilitic virus in the establishment of the amentia: is its solitary action responsible for the mental defect, or are other factors implicated? Mr. Stephens specifies such factors as neuropathic inheritance, alcoholism, consanguinity, antenatal adverse mental or physical states of the mother, and finds that in no one of his cases was the syphilitic virus unassociated with at least one of these etiological components. He draws the cautious conclusions that it appears to be the essential factor in 25 cases, the exciting or deter-

minant factor in 6, an auxiliary or augmentary factor in 11. In his series of 11 mongols 3 gave a positive reaction; 2 of 4 cretins and 10 of 17 epileptic idiots gave a similarly positive result. It is difficult to know what significance to attach to the findings in the mongols and cretins. The mongol type, from both psychic and somatic view-points, is so well defined, so systematised, that syphilis can scarcely be regarded as an essential factor if only three of 11 cases are positive, and there would appear to be equal difficulties in the way of regarding that factor as determining or even auxiliary. Mr. Stephens says little in his paper of the hypothesis of mere coincidence, yet in regard to both cretins and mongols it may be asked whether the occurrence of a syphilitic taint is not simply accidental. In his summing-up, indeed, he declares that in none of his cases did the syphilitic virus appear to be *wholly* responsible, but seemed rather to have been associated with and to have acted upon "inherently defective, diseased and degenerated, or damaged tissues." As the Belgian Professor Bordet was the first to discover and establish the essential principle of the "Wassermann" test, Mr. Stephens holds that the proper name should be the "Bordet-Gengou phenomenon in syphilis," but he prefers the simpler term "compluetic reaction," coining the word "compluetic" from the two words "complement" and "luetic."

TRICHINOSIS AND NEOSALVARSAN.

IT has hitherto been supposed that no direct measures could have any beneficial influence upon the trichinae when once the muscles had been invaded, but a striking case of, at any rate, immediate relief, following an intravenous injection of neosalvarsan, in a case of trichinosis is reported in the *Journal of the American Medical Association* (1916, lxxvii., p. 1086) by Dr. J. B. McNeerthney and Dr. W. B. McNeerthney. The patient was a German, aged 33. He had eaten for some days some undercooked ham, and was in the fifteenth week of the infection when admitted into hospital. He was greatly emaciated, prostrated, and had lost 60 lb. in weight. The temperature was 100° F. The forearms were flexed; restriction of movements at the wrist; rigidity of the neck muscles and even difficult deglutition. The lower limbs showed cyanosis and oedema. There was severe anaemia and the eosinophiles were increased to 35 per cent. A section of muscle fibre showed numerous living trichinae in every field. An intravenous injection of 0.6 gramme¹ neosalvarsan was given. A marked chill followed, but within 48 hours the patient felt less pain than he had had for months. Within a week he was able to sit in a chair and could extend his forearms. Complete and uneventful recovery followed. This is a striking therapeutic triumph in one instance, and its effects in other cases will be awaited with interest.

THE TREATMENT OF PROSTATIC HYPERTROPHY BY NERVE-SECTION.

AMONG the papers read to the members of the Dutch Medical Association at the summer meeting at Leyden was one² by Dr. D. Schoute on the treatment of hypertrophy of the prostate by section of the nerves in the spermatic cord. The idea of the treatment was suggested to Dr. Schoute by the

¹ The authors write 0.66 gramme but from the references given and the absence of any remark calling attention to the minuteness of the dose, it would seem that 0.6 gramme is intended.

² Nederl. Tijdschr. voor Geneesk., Amsterdam, 1916, 1., 1356.

rapid relief from retention of the urine that sometimes follows the operation of castration. This led him to treat a patient with hypertrophied prostate who was suffering from retention by injecting novocaine into the spermatic cord in order to cut off the transmission of nervous impulses from the testes to the prostate. The injections were successful, as they relieved the retention by enabling the patient to pass urine again; but they failed in so far as they required repetition every three hours, by which time their effects had passed off. The operation proposed by Dr. Schoute aims at exposing the spermatic cord, separating off the vessels and vas deferens, and cutting through the tissues of the cord that remain. Discussing his results, Dr. Schoute remarks that he finds it convenient to divide up his prostatic patients into two classes, irrespective of the stage they had reached—namely, those without and those with prostatic pains. He has applied his operation in 31 cases of hypertrophy of the prostate with retention of urine or residual urine. So far as his classification goes, 17 of the patients had severe prostatic pain (9 with cystitis or prostatitis), 12 had little or no pain (3 with slight cystitis), and 2 were demented whose sensations could not be ascertained. Six of his patients died within three weeks of the operation; all were cases with complete retention. The operative results are set out with the patients in three groups. Group A contains 5 patients who had pain and complete retention; 2 were cured, 2 were unimproved, and 1 died. Group B comprises 12 patients with pain and residual urine amounting to from 1 to 18 oz.; 5 were cured, 2 improved, 3 unimproved, and in 2 the results were uncertain. Group C contains 12 patients without pain, but with complete retention; 9 were cured by the operation; 3 died. Both the demented, who also were hemiplegic, died. Dr. Schoute concludes that this operation is indicated for the relief of patients with hypertrophy of the prostate who do not suffer from severe prostatic pains, adding that cystitis and prostatitis lessen the probability that it will be successful. The operation is not found to disturb the sexual functions; Dr. Schoute has not observed it to lead to a reduction in the size of the hypertrophied prostate. A discussion followed the reading of this paper; the opinions expressed as to the value of the operation advised by Dr. Schoute were unfavourable. Dr. Van Cappellen had performed it in 12 cases without a single successful result; Dr. Vermeij and Dr. Montaigne each had two cases to record, all of them unsuccessful. Dr. Laméris observed that the operation had been tried 20 years ago, and had then been found wanting; he criticised Dr. Schoute's classification of his patients and the scarcity of the clinical details of his cases. Dr. Sträter remarked on the high immediate mortality of the operation—6 deaths among 31 patients. In the course of his reply Dr. Schoute said that it often was very difficult to free the spermatic artery from the cord, and expressed the belief that the treatment of prostatic hypertrophy by section of the vas deferens was a failure if nothing more than the vas was divided.

At a meeting of the Medical Society of London to be held on Monday next, Nov. 13th, at 8.30 P.M., Captain Langdon Brown, R.A.M.C. (T.), will open a discussion on "Epidemic Nephritis." Among others, the following have promised to take part in the discussion: Sir William Osler, Lieutenant J. S. Dunn, R.A.M.C., Dr. Samuel West, Mr. J. E. Adler, Mr. W. H. Jessop, and Dr. T. J. Horder.

REPORT OF THE COUNTY MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER OF LONDON FOR 1915.¹

THE present is Dr. W. H. Hamer's fourth annual report in his dual capacity as medical officer of health and school medical officer. It relates to the year 1915 and gives account of the sanitary and educational work of the County Council in relation to the war. As in previous reports, the subject-matter is arranged under two headings, dealing respectively with Public Health and Elementary Education. In the following comments we shall adhere to the same arrangement.

PART I.—PUBLIC HEALTH.

In this section of his report Dr. Hamer acknowledges that "the health of London during 1915 does not compare very favourably with that of quite recent years—not so much on account of any influence of the war as owing to increase of deaths at relatively high ages attributable to a prevalence of influenza and respiratory diseases during the winter months." In many respects this report is very encouraging, inasmuch as it confirms the evidence of previous years as to steady and substantial administrative progress. In spite of difficulties inseparable from existing war conditions, a commendably high standard of efficiency continues to be maintained in the sanitary service of the county. Nevertheless, Dr. Hamer rightly insists that exceptional efforts are still needed in order to deal satisfactorily with war emergencies, which, far from diminishing, still threaten to increase *pari passu* with the duration of hostilities. At the date of the report five metropolitan medical officers of health and 53 sanitary inspectors had already been detached for war service. The inspecting staff was therefore depleted to the extent of 16 per cent. Probably for reasons of economy the tabular portions of this report have been curtailed. Nevertheless, all that is essential in the statistical contents of previous reports has been continued in the summary tables now presented, for the means of compiling which Dr. Hamer acknowledges his indebtedness to the district medical officers of health.

Population changes.—In the course of 1915 the population of London experienced important changes, not only in respect of number, but of age and sex constitution and local distribution. Consequently it has become necessary to calculate mortality rates upon a population from which deduction has been made for men on active service, the deaths having been similarly reduced so as to relate to civilians exclusively. The total civil population was estimated at 4,310,030. In order to obtain data relating to this number the deaths among members of His Majesty's forces have been excluded, and the rates for the civil population thus computed. The rates now given are the best that can be obtained in present exceptional circumstances, but caution is obviously requisite in comparing these with the rates of normal years. The civil population is deficient in males of military ages (from 19–40 years), at which time of life mortality is considerably below that of the normal aggregate population. For this reason the rates calculated on the civil population are to some extent overstated.

Marriage-rate.—The metropolitan rate of marriages has been rising almost steadily for several years, the rate having increased from 16.9 in 1909 to 19.2 in 1914. The estimated *civil population* cannot properly be used for calculating the marriage-rate, since the numbers married include many men on active service. But, taking a *probable population* of 4½ millions the rate for 1915 would be 25.9 per 1000, which is the highest rate on record. The bulk of this exceptional increase is directly attributable to the war. It is believed, however, that a considerable number of persons registered as married in London were not actually resident in the county.

Birth-rate.—A serious fall in the birth-rate of London still continues. It was 23.6 in the year under notice, against an average of 25.0 in the quinquennium 1909–13. Dr. Hamer devotes considerable attention to the steady fall of the birth-rate, which has been practically continuous for the last 40 years. A theory which has met with some acceptance ascribes this—not to natural causes, such as the high

¹ Published by King and Son, Westminster. Pp. 40. Price 1s.

rate of marriages, economic factors, emigration, &c.—but to the artificial limitation of families. One of the most cogent reasons against this theory is the fact that the fall is widespread throughout Europe, and affects certain other civilised communities. In this connexion the medical officer of health quotes Mr. Uday Yule, who has long been engaged on a critical study of the subject. In a recent communication this expert statistician has observed:—

It was precisely the extraordinary similarity of the changes in very widely different countries that made it very difficult for him to accept the purely moral theory. If there had been a change in that way—and possibly it was the case—why did the changes take place in so many different countries in almost the same year? People did not change their morality in a large number of different countries, or even in one country, at a given point of time without some extremely definite cause, and he was still inclined to regard economic factors of some kind as lying behind it.

For the purpose of his study Mr. Yule examined various economic factors—wages, consumption of commodities, exports and imports, &c.—and was led to attach special importance to the correlation of the marriage- and birth-rates with the course of prices. He concludes:—

I feel myself almost compelled to the belief that the course of prices, either directly by its influence on consuming power and on profits, indirectly by effects on trading, or more indirectly (if it be possible) as an index to the course of some other variable, has been throughout the past century the factor of most outstanding importance in the rate of reproduction of the race.

This controversy is by no means settled, and, having regard to its vital importance, we shall welcome further discussion of the subject.

Deaths and causes of mortality.—Calculated on the estimated civil population the deaths among civilians in the administrative county were equal to a rate of 16.8 per 1000 living, as compared with 14.6 in the year 1914. The increased deaths appear to be due in greater degree to unfavourable weather in the winter of 1915 than to excess of deaths at military ages attributable to the war. The increased mortality among children under 5 years was mainly due to measles and respiratory affections in the winter months, whilst at ages above 55 influenza, with its chest complications, was responsible for the greater part of the increase.

Infectious Diseases.

The incidence and fatality of the more familiar infectious diseases are set forth in detail in the periodical returns of the Registrar-General; they are therefore dealt with summarily in the present report. Measles was a notifiable disease last year in Paddington only. The deaths in London from that disease numbered 2286, or 910 more than in 1914. The incidence of measles appears to have been exceptionally heavy upon the Western and South-Western boroughs. The civilian cases of scarlet fever notified last year numbered 16 974, and were fewer by 8041 than the number in 1914. The decreased prevalence of this disease was shared by each of the metropolitan boroughs with the exception of Shoreditch and Bethnal Green, where the cases were greatly in excess. The notified civilian cases of diphtheria numbered 909, or almost exactly the same as in the preceding year. In London as a whole the prevalence of diphtheria appears to rise and fall with that of scarlet fever; but this is not true of the metropolitan areas separately. In 27 out of the 29 boroughs the scarlet fever cases notified last year showed a marked decline as compared with 1914, but in the case of diphtheria only 16 showed a decline. This difference is apparently associated with greater tendency to persistence in particular places in the case of diphtheria as compared with scarlet fever. Whooping-cough was a notifiable disease last year in Holborn, Lambeth, and Greenwich; the deaths in London from this disease numbered 1158, or 237 more than in 1914.

Enteric fever.—Since the beginning of the century the incidence has been low in London, especially in the last ten years. The decrease observed in London has not been confined to that county, or indeed to England and Wales. Speaking generally, it appears to have been common to most European countries. During the first half of the period elapsed since 1900 the marked autumnal rise previously manifested from year to year has steadily diminished in extent, and since 1908 it has been evident in two years only. The first year of this series of 15, in which a marked failure occurred in the usual autumnal prevalence, was 1907, the autumnal excess being then smaller

than in any previous year back to the introduction of notification. Since 1911 it has almost entirely disappeared. Notwithstanding the return to this country of convalescent soldiers and the concomitant abnormal conditions of the time, no increase in prevalence of enteric fever was observed last year. The number of attacks notified among civilians was 607, and was considerably below the number reported in 1914. From inquiries made it appears that fewer than 20 deaths from enteric fever occurred during the year among the military population of London; from which circumstance it may be inferred that if the whole of the military cases had been notified the total attacks in London during 1915 would still have been substantially fewer than in the preceding year. As in past years, Dr. Hamer has again been eager to obtain information respecting the suspected sources of infection in the reported cases, and in 380 instances he has been materially assisted by his district medical colleagues. The information thus acquired threw suspicion upon food (fish, shell-fish, &c.) in 143 cases, in 55 of which the patients were soldiers and in 5 Belgian refugees. In 43 cases infection appears to have been contracted outside London, and 57 cases were ascribed to contact infection; whilst in 74 instances the diagnosis of enteric fever was found incorrect. Dr. Hamer does not neglect to caution his readers that "in all these instances the grounds upon which the suspicions as to origin were based must be regarded as having only some degree of probability far removed in many instances from certainty."

Cerebro-spinal fever and influenza.—The order of the County Council requiring the notification of cerebro-spinal fever came into operation in 1907, since which date considerable attention has been directed to the etiology of that condition. During the seven years following the introduction of this measure the disease did not assume epidemic dimensions. In his last two reports Dr. Hamer has devoted considerable space to an examination of its probable relationship to influenza. In the first of these the attempt was made to discover whether the concurrence of influenza and cerebro-spinal fever was more frequent than mere chance coincidence would account for. The answer, it will be remembered, was in the affirmative.² In the last Army and Navy Report reference has been made to this subject. In that document Surgeon-General H. D. Rolleston remarks upon the coincidence with the outbreak of cerebro-spinal fever in 1915 of catarrh, influenza, tonsillitis, and sore-throat. He concludes that there appears to be a relation between the incidence of catarrhal affections on the one hand and of cerebro-spinal fever on the other. Further reports on the same subject are cited—one by Dr. Bruce Low and another by Captain Michael Foster and Captain J. F. Gaskell, of the Eastern Command. The last-named observer concludes that mild cases of cerebro-spinal fever may be unrecognised and classed as influenza, but that no proof exists that the former disease is ever so slightly marked as not to develop at least some of the diagnostic signs. This subject is of particular importance at the present time, in the interest not only of the civil community but of His Majesty's Forces at home and abroad. We therefore commend Dr. Hamer's instructive observations to the study of our medical readers.

Pulmonary tuberculosis.—Among the civilian population the deaths thus returned last year corresponded to a rate of 1.60 per 1000. This rate is not fairly comparable with that of 1.43 for 1914, when the age composition of the community was normal. Recruitment for the war reduced the proportion of healthy males aged 19–40, leaving in the civil population all those who had been rejected on account of phthisis, the result being to overstate the mortality based on the civil population when contrasted with that of the previous year. The increase in 1915 cannot properly be attributed to the war, for excessive mortality is also shown at ages both below and above the years of active service. In the year under notice 14,712 cases of phthisis, or 1755 fewer than in 1914, were notified in London. Systematic notification was not established until 1913, consequently uncertainty attaches to comparison of the returns; moreover, at the outset all cases, however far advanced, were notifiable as "primary," and some old-standing cases may in that way have escaped notification.

Anthrax.—This disease is of very rare occurrence in London, the reported cases in human beings having never exceeded nine in any year of the last five. Early in 1915

² See THE LANCET, April 15th, 1916, p. 833.

seven cases of human anthrax were reported. Infection by anthrax spores was traced to the use of shaving brushes made from goats' hair which had been consigned from abroad to a manufacturer in the Midlands, who used the hair for making shaving brushes.³ These are the first known instances of anthrax being traced to infection from shaving brushes; and but for the timely discovery of Dr. R. R. Elworthy, of the West London Hospital, and the administrative action subsequently taken, an outbreak of more serious dimensions might have occurred. As many of the infected brushes as could be discovered in London were collected and dealt with by the metropolitan medical officers of health, but a large number appear to have been distributed to dealers, both in the provinces and on the continent, and could not be traced.

(To be concluded.)

THE CONTROL OF VENEREAL DISEASES.

The Resolutions of the Royal College of Physicians of London.

At the Comitia of the Royal College of Physicians of London held on Oct. 26th two valuable resolutions with reference to the control of venereal diseases were passed,¹ copies of which have been sent to the Prime Minister, the Home Secretary, and the President of the Local Government Board. The first of these resolutions set out the opinion of the College that until the treatment of these diseases by unqualified persons is rendered illegal the measures for their control will be much hampered; the second was directed towards the prevention of the main inducement for the public to consult quacks and to try quack remedies—viz., the advertisements in lay papers. The resolution of the College took the form of an endorsement of recommendation 58 (iii.) of the Patent Medicines Committee of the House of Commons, which runs as follows:—"That all advertisements of remedies for diseases arising from sexual intercourse or referring to sexual weakness be prohibited." This recommendation has received the support of the Royal Commission on Venereal Diseases, and it is earnestly to be hoped that the Government will recognise the urgency of the situation. A great effort is being made, in unusually favourable circumstances, to remove the curse of these diseases from our population. Public money is to be spent with unprecedented generosity in carrying out immediately the recommendations of the Royal Commission on Venereal Diseases, and already the medical profession and the municipal authorities of many areas are organising the beneficent work. No factor which is generally and authoritatively acknowledged to be opposing the movement for the control of venereal diseases should be allowed to exist when it can be eliminated with ease.

The Scottish Regulations.

The Local Government Board for Scotland has, after three months' interval, followed the example of the English Board and issued regulations dealing with the treatment of venereal diseases. The Order bears the heading, "The Public Health (Venereal Diseases) Regulations (Scotland), 1916," is dated Oct. 26th, 1916, and is issued "to all local authorities in Scotland: and to all others whom it may concern." It differs only in minor details from the English Order, and directs that every local authority shall prepare and submit a scheme for the approval of the Board arranging for (1) a scientific report on material sent by medical practitioners for diagnosis; (2) the treatment in hospitals or other institutions or in their homes of persons suffering from venereal diseases; (3) skilled assistance in treatment to be placed at the disposal of practitioners; and (4) the supply to practitioners of salvarsan or other drugs for the treatment and prevention of venereal diseases. The local authority may make what provision it thinks desirable for public instruction. The Board undertakes to make grants in respect of approved schemes to the amount of 75 per cent. of the net outlay.

In a covering letter addressed to the clerk of the local authority the Board expresses its willingness to give the assistance and advice of one of its medical inspectors to any medical officer of health desiring such help, and suggests the desirability of combination among local

authorities for carrying out schemes. In another letter addressed to the secretary of the hospital, the Board trusts that hospital authorities will be willing to confer with local authorities in their area with regard to arrangements for treatment; any extra expenditure incurred in providing additional hospital facilities will be borne by the local authority, and while in so doing the hospital will be under the inspection of the Board, no interference in the administration of the hospital is contemplated. In case of shortage of medical staff the Board has received the assurance of the Army Council that wherever possible specially experienced officers of the Royal Army Medical Corps will be enabled to give such assistance at hospitals as their military duties permit. In a third letter addressed to the inspector of poor, the Board proposes to make grants in respect of special expenditure incurred by Poor-law authorities in carrying out treatment in their institutions, provided that a statement of the nature and extent of such treatment is submitted and approved. Appendices attached to the memorandum include excerpts from the Report of the Royal Commission and from the technical parts of Dr. Newsholme's memorandum issued by the English Board.

The Remuneration of Medical Officers of Treatment Centres.

The Council of the British Medical Association has drawn up a series of resolutions in regard to the remuneration of the medical officers attached to the proposed clinics for venereal diseases. These resolutions, which have been circulated to the branches for adoption by the next Representative Meeting, are as follows:—

1. That whole-time senior medical officers of clinics should be appointed in country areas only where the work cannot be distributed among the members of the local profession.
2. That the remuneration of part-time clinical assistants of clinics should not be less than £1 1s. per session (not exceeding 2½ hours).
3. That the remuneration of part-time senior medical officers of clinics be: In London (for one or two sessions per week not exceeding 2½ hours), £3 3s. per session, (for three or more sessions per week) £2 12s. 6d. per session; in the provinces £2 2s. and £1 11s. 6d. respectively per session.
4. That commencing salaries of whole-time senior medical officers of clinics be not less than £750 per annum, exclusive of travelling expenses.
5. That a whole-time assistant to a part-time senior medical officer be paid not less than £350 per annum, if non-resident, exclusive of expenses.

Conference at Bangor.

A conference of medical men of the North Carnarvonshire and Anglesey areas took place last week at Bangor to consider local schemes for the diagnosis and treatment of venereal diseases. Dr. Marion E. Mackenzie occupied the chair and an address was given by Major G. M. Dobson, R.A.M.C. A resolution in favour of compulsory notification, proposed by Dr. James Craig, was withdrawn, and support promised to the Local Government Board scheme.

THE SERVICES.

THE INDIAN MEDICAL SERVICE.

NOMINATIONS FOR APPOINTMENTS.

It has been announced in the press that after the open competitive examination held in July, 1915, for admission to the Indian Medical Service no similar examination would be held during the continuance of the war, but that such appointments as might be required to meet the absolutely indispensable needs of the service would be made by nomination by the Secretary of State. To assist him in making these appointments which, as already announced, will be limited in number to the absolutely indispensable needs of the service, Mr. Chamberlain has appointed a selection committee who will summon and interview such applicants as may appear to be *prima facie* suitable, and make recommendations for appointment. Applications for appointment should be addressed to the Secretary of the Military Department, India Office, Whitehall, S.W., and should contain concise particulars of the applicant's medical degrees and career. Applicants must be over 21 and under 32 years of age at the time of application. Particulars regarding pay, promotion, &c., in the service can be obtained from the Secretary, Military Department.

ROYAL NAVAL MEDICAL SERVICE.

The following appointments have been notified:—Staff-Surgeon: W. N. L. Cherry to *Victory*, additional, for disposal. Surgeons: A. Simpson to *Victory*, additional, for disposal; G. E. D. Ellis to *Wildfire*, for Sheerness Barracks

³ THE LANCET, Jan. 1st (p. 20) and 29th (p. 242), 1916.

¹ THE LANCET, Nov. 4th, 1916, p. 801.

and Yard; and W. E. Lloyd to *Diamond*. Temporary Surgeons: W. B. Gabriel to *Pembroke*, additional, for Chatham Hospital; and W. H. Coldwell and F. M. Allchin to *Victory*, additional, for Haslar Hospital.

Surgeons to be Staff-Surgeons: T. R. L. Jones, J. H. Burdett, A. V. J. Richardson, and G. R. McCowen.

To be temporary Surgeons: W. H. Blackburn, W. J. Colborne, and J. F. Haynes.

ARMY MEDICAL SERVICE.

Lieutenant-Colonel W. Pasteur, R.A.M.C. (T.F.), to be temporary Colonel and Lieutenant-Colonel M. MacG. Rattray to be temporary Colonel whilst Assistant Director of Medical Services of a Division.

ROYAL ARMY MEDICAL CORPS.

C. J. S. Stewart, C.A.M.C., from Honorary Major, to be temporary Captain.

Temporary Captain J. A. Turner, C.I.E., relinquishes his commission.

Temporary Lieutenants to be temporary Captains: T. D. Miller, T. H. Harker, W. H. Whitehouse, R. Brookes, C. A. Verge, and J. C. Bawden.

To be temporary Captains: J. R. Irwin, C.A.M.C. (late Lieutenant, R.A.M.C.), and J. D. Bruce, C.A.M.C.

Captain L. J. Violette, C.A.M.C., relinquishes his temporary commission on account of ill-health.

Temporary Lieutenants relinquishing their commissions: J. J. M. Dowzer, J. F. Adamson, A. Ross, P. N. Allman, and A. W. Wakefield.

To be temporary Lieutenants: H. Bowring, A. P. Piggot, T. G. Fenton, C. Duncan, F. J. Lennan, S. W. H. Stuart, R. A. Smith, R. Calleya, T. Clapperton, J. Geoghegan, J. Rickards, J. S. Strachan, Temp. Hon. Lieut. G. C. Hartley, C. T. MacL. Plowright, W. McAlpine, A. J. Macvie, D. N. Anton, G. W. Bury, Temp. Hon. Lieut. W. A. Hotson, H. J. Simson, J. L. Scott, R. J. McPeeters, T. Waterhouse, D. F. Riddell, M. F. Tylor, M. H. Laslett, C. Hackney, W. J. Smyth, W. H. Canter, C. R. Brown, H. Goodale, C. C. Fissette, J. R. Anderson, F. B. Macdonald, P. A. Storey, R. J. Gordon, H. Heathcote, S. H. Ryan, R. W. Nairn, S. A. Owen, T. B. Sellors, W. S. Wildman, F. J. Spilsbury, J. M. Christie, J. S. Young, D. C. P. Taylor, T. E. Flitcroft, J. F. H. Stallman, C. J. N. Longridge, and A. I. Simey.

E. G. Grove to be Temporary Lieutenant whilst employed at the Lord Derby War Hospital.

R. H. Campbell to be temporary Honorary Captain whilst employed at the British Red Cross Hospital, Netley.

Temporary Honorary Lieutenant R. Marshall to be temporary Honorary Captain.

TERRITORIAL FORCE.

Highland Field Ambulance; Lieutenant B. L. Davis to be Captain.

East Lancashire Field Ambulance: Lieutenant E. Hulme to be Captain.

London General Hospital: Lieutenant-Colonel W. Pasteur is restored to the establishment and seconded whilst holding a commission as temporary Colonel, Army Medical Service.

London Field Ambulance: Lieutenant O. Gleeson to be Captain.

London Sanitary Company: Lieutenant J. Inglis to be Captain.

Home Counties Field Ambulance: Captain (temporary Major) T. H. Chittenden, from Attached to Units other than Medical Units, to be Captain.

West Riding Field Ambulance: Captain H. H. Emmerson resigns his commission.

Northern General Hospital: Captain W. E. F. Tinley, from Attached to Units other than Medical Units, to be Captain, whose services will be available on mobilisation. Captain W. E. F. Tinley to be Major on the permanent personnel.

Attached to Units other than Medical Units.—Captain F. Philip to be temporary Major whilst acting as Registrar of a General Hospital.

JOURNAL OF THE ROYAL ARMY MEDICAL CORPS.

The first article in the current issue of this journal is contributed jointly by Mr. Albert Morison, honorary surgeon to the Red Cross Hospital, Sunderland, and Lieutenant William J. Tulloch, lecturer in bacteriology at the University of St. Andrews, and deals with the treatment of wounds in war by magnesium sulphate. The article, which is illustrated with coloured plates, while emphasising the utility of MgSO₄ as a curative dressing, does not suggest its use as a first dressing for fresh wounds. Dr. I. Walker Hall and Dr. B. A. I. Peters, with the assistance of Mr. F. Nicholls, discuss in a joint paper the changes in the agglutinability, fermentation reactions, and absorptive capacities of the meningococcus during the active attack; Captain T. S. Allen relates some interesting experiences of X ray work in France; and Lieutenant-Colonel Netherville Barron, M.V.O., has a thought-compelling note in regard to physical training with especial reference to the training of convalescents. The subject is an important one both in its bearing on the rapid

return to the firing line of men who have been wounded, and on the cure of the convalescent soldier after the war. Captain H. L. Tidy and Lieutenant I. P. S. Dunn discuss the differential bactericidal values of malachite and brilliant green for the typhoid-coli group, and Captain T. H. Whittington publishes a report on the use of stock vaccine in infection by the bacillus typhosus, with an analysis of 230 cases.¹

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In the 96 English and Welsh towns with populations exceeding 50,000 persons at the last Census 7462 births and 4182 deaths were registered during the week ended Saturday, Nov. 4th. The annual rate of mortality in these towns, which had been 12.2, 11.8, and 12.9 per 1000 in the three preceding weeks, fell in the week under notice to 12.6 per 1000 of their aggregate civil population estimated at 17,312,295 persons for the year 1915. During the first five weeks of the current quarter the mean annual death-rate in these towns averaged 12.4, against 12.1 per 1000 in London. Among the several towns the death-rate last week ranged from 3.2 in Ilford, 5.5 in Wimbledon, 6.6 in Lincoln and in Swansea, 6.8 in Enfield, and 7.0 in Ipswich, to 17.1 in Nottingham, 17.3 in Darlington, 18.1 in Bury, 19.1 in Bradford, and 19.3 in Norwich.

The 4182 deaths from all causes were 86 below the number in the previous week, and included 229 which were referred to the principal epidemic diseases, against 306 and 316 in the two preceding weeks. Of these 229 deaths, 131 resulted from infantile diarrhoeal diseases, 39 from diphtheria, 22 from measles, 20 from whooping-cough, 12 from scarlet fever, and 5 from enteric fever, but not one from small-pox. The annual death-rate from these diseases was equal to 0.7, against 1.0 per 1000 in the previous week. The deaths of infants (under 2 years) from diarrhoea and enteritis, which had declined from 477 to 221 in the seven preceding weeks, further fell to 131, and included 31 in London, 13 in Liverpool, 11 in Manchester, 10 in Birmingham, and 9 in Leeds. The deaths referred to diphtheria, which had been 45, 40, and 53 in the three preceding weeks, declined to 39, of which 12 occurred in London, and 3 each in St. Helens and Manchester. The fatal cases of measles, which had decreased from 25 to 13 in the four preceding weeks, rose to 22; 5 deaths were registered in London and 2 each in West Ham, East Ham, Birmingham, and Sheffield. The deaths attributed to whooping-cough, which had been 23, 10, and 13 in the three preceding weeks, rose to 20, and included 4 in Birmingham, 3 in Liverpool, and 2 each in St. Helens and Cardiff. The deaths referred to scarlet fever, which had declined from 13 to 5 in the four preceding weeks, rose to 12, of which 3 occurred in Liverpool. The fatal cases of enteric fever, which had been 11 in each of the two preceding weeks, fell to 5, and included 2 in Burnley.

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had been 1074, 1067, and 1130 at the end of the three preceding weeks, further rose to 1141 on Saturday last; 146 new cases were admitted during the week, against 167, 125, and 197 in the three preceding weeks. The cases of diphtheria, which had increased from 1262 to 1490 in the seven preceding weeks, further rose to 1528; 186 new cases were admitted during the week, against 194, 188, and 231 in the three preceding weeks. These hospitals also contained on Saturday last 62 cases of measles, 47 of enteric fever, and 39 of whooping-cough, but not one of small-pox. The 1054 deaths from all causes in London were 1 in excess of the number in the previous week, and corresponded to an annual rate of 12.8 per 1000. The deaths referred to diseases of the respiratory system, which had been 132, 132, and 142 in the three preceding weeks, further rose to 164 in the week under notice.

Of the 4182 deaths from all causes in the 96 towns, 182 resulted from violence, 382 were the subject of coroners' inquests, and 1283 occurred in public institutions. The causes of 41, or 1.0 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Leeds, Bristol, West Ham, Newcastle-on-Tyne, Hull, and in 71 other smaller towns. Of the 41 uncertified causes, 7 were registered in Birmingham, 6 in Liverpool, 3 each in London, Bootle, and Gateshead, and 2 each in Manchester, Preston, Middlesbrough, and Darlington.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns with an aggregate population estimated at 2,372,000 persons at the middle of this year 1000 births and 635 deaths were registered during the week ended Saturday, Nov. 4th. The annual rate of mortality in

¹ See THE LANCET, vol. i., 1916, pp. 753 et seq.

these towns, which had been declined from 15.1 to 12.9 per 1000 in the four preceding weeks, rose to 13.9 per 1000 in the week under notice. During the first five weeks of the current quarter the mean annual death-rate in these towns averaged 13.7, against a corresponding rate of 12.4 per 1000 in the large English towns. Among the several towns the death-rate last week ranged from 7.2 in Perth, 7.4 in Motherwell, and 8.9 in Kirkcaldy, to 17.1 in Ayr, 17.3 in Aberdeen, and 18.4 in Leith.

The 633 deaths from all causes were 46 above the number in the previous week, and included 51 which were referred to the principal epidemic diseases, against 53 in each of the two preceding weeks. Of these 51 deaths, 18 resulted from infantile diarrhoeal diseases, 11 from measles, 10 from diphtheria, and 4 each from enteric fever, scarlet fever, and whooping-cough, but not one from small-pox. The death-rate from these diseases was equal to 1.1, against 0.7 per 1000 in the large English towns. The deaths of infants (under 2 years) from diarrhoea and enteritis, which had declined from 66 to 19 in the four preceding weeks, numbered 18, and included 6 in Glasgow, and 2 each in Edinburgh, Dundee, Leith, and Coatbridge. The deaths referred to measles, which had been 16, 2, and 18 in the three preceding weeks, fell to 11, and comprised 8 in Dundee, 2 in Glasgow, and 1 in Edinburgh. The fatal cases of diphtheria, which had been 4, 12, and 4 in the three preceding weeks, rose to 10, and included 3 each in Glasgow and Aberdeen. Of the 4 deaths from enteric fever, 2 occurred in Glasgow and 2 in Kilmarnock. The deaths attributed to scarlet fever, which had been 7, 3, and 5 in the three preceding weeks, were 4 last week, but showed no excess in any particular town. The 4 fatal cases of whooping-cough were slightly in excess of the average in the earlier weeks of the quarter.

The deaths referred to diseases of the respiratory system, which had been 90, 74, and 87 in the three preceding weeks, rose to 95 in the week under notice, but were 55 below the number registered in the corresponding week of last year. The deaths from violence numbered 25, against 26 and 30 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the registration area of Dublin 187 births and 121 deaths were registered during the week ended Saturday, Nov. 4th. The annual rate of mortality, which had been 17.7, 17.5, and 18.7 per 1000 in the three preceding weeks, fell to 15.9 in the week under notice, against 12.8 and 13.3 per 1000 in London and Glasgow respectively.

The 121 deaths from all causes included 30 of infants under 1 year and 26 of persons aged 65 years and upwards. Five deaths (of infants under 2 years) were referred to diarrhoeal diseases and 3 to enteric fever. The causes of 12 deaths were uncertified, and those of 2 others were the subject of coroners' inquests, while 33, or 27 per cent., of the total deaths occurred in public institutions.

During the same period 135 births and 119 deaths were registered in the city of Belfast. The deaths corresponded to an annual rate of 15.9, against 15.8 per 1000 in the previous week, and included 21 of infants under 1 year and 32 of persons aged 65 years and upwards. Four deaths (of infants under 2 years) were referred to diarrhoeal diseases and 1 to whooping-cough. The causes of 3 deaths were uncertified, and those of 3 others were the subject of coroners' inquests, while 31 of the total deaths occurred in public institutions.

CLERICAL, MEDICAL AND GENERAL LIFE ASSURANCE SOCIETY.—At the 92nd annual meeting of this society, held at the offices in St. James's-square, S.W., on Nov. 3rd, a satisfactory report was submitted. The report showed that after providing over half a million sterling for depreciation and war claims, a 2½ per cent. valuation had been maintained, and £197,602 additional reserves had been laid by. The bonus available for distribution was equal to that of 1911, the largest in the history of the society. The net new business, though checked by the war, had increased from £672,732 to £737,472.

MANCHESTER BABIES' HOSPITAL.—A pamphlet of 44 pages contains the monthly reports from August, 1915, to July, 1916, of the Manchester Babies' Hospital at Slade-lane, Levenshulme, signed by the medical registrar, Dr. Gertrude H. Hickling. Ninety-four babies (50 male, 44 female) were admitted during the year; on account of acute gastro-enteritis (9), chronic dyspepsia and mal-nutrition (83). Two were found normal after admission. During the year 60 were discharged improved, 2 were transferred, 2 were taken home by their parents, and 4 were discharged unimproved on account of whooping-cough. Thirteen babies died; of the deaths 5 were from generalised tuberculosis. The age varied from less than one month to 12 months; the large majority being between two and six months. The average duration of stay in the hospital was 76 days. The cases admitted were not selected, but were taken in whenever there was a vacancy at the request of infant welfare centres, the medical officer of health, or private doctors.

THE EDITH CAVELL HOMES OF REST FOR NURSES.

To the Editor of THE LANCET.

SIR,—An appeal to the public is now being made on behalf of these homes. They are urgently needed, so that the noble women who work in our hospitals in these days of stress may, when overwrought, obtain a much-needed rest. Those of us who have to deal with hospitals are only too painfully aware how pressing this need is becoming. Some officers who have benefited by the unselfish ministrations of these devoted women have from time to time expressed to me their desire that a channel might be provided through which either officers or those in the ranks could give practical expression to their gratitude according to ability, and I venture to think that the project to establish homes of rest for nurses in memory of Edith Cavell offers to them an ideal opportunity for fulfilling their wish.

May I hope, therefore, that the appeal now being made may meet with the ready and generous response from our military forces which it deserves, and that subscriptions will flow in to the honorary secretary of the Edith Cavell Homes of Rest for Nurses, 25, Victoria-street, Westminster, S.W.

I am, Sir, yours faithfully,

DOROTHY HAIG.

St. James's Court, Buckingham Gate, S.W., Nov. 4th, 1916.

MASSAGE AND MEDICAL ELECTRICITY IN THE AFTER-TREATMENT OF CONVALESCENT SOLDIERS.

To the Editor of THE LANCET.

SIR,—Dr. Florence Lambert's report in your issue of Nov. 4th demonstrates how necessary was the paragraph to which she takes exception. The military convalescent hospitals have nothing to do with the question, since they are designed for such sick and wounded as "are likely to become quite fit to return to an Expeditionary Force within a maximum period of six weeks." So her remarks on these are beside the point.

Regarding the Command Dépôts, it is clearly of national importance that they should be equipped with every appliance which can reasonably be expected to lessen disability to the utmost extent in the briefest possible time. As a matter of fact, we know they are in certain instances far better equipped than, in order to push her own special views, she describes them. In one, at all events, Heaton Park, which was organised by a very able Canadian, Major Tait McKenzie, an admirable system of treatment, much on the lines of the Grand Palais in Paris, has been initiated, and is giving the good results which might be expected. In another, Ripon, I understand that similar methods, still further improved by the addition of diathermy, are being brought into use. But, unhappily, on the other hand, I hear of a third whose equipment and staff of masseuses is wholly inadequate.

Some of Dr. Lambert's inaccuracies need immediate correction. It is not correct to imply that the Grand Palais patients are not continuously treated or kept under proper discipline; she evidently has not read Dr. Camus's last report, issued in February. It is a pure assumption that the results of French massage are worse than those of English. It is untrue that the Zander treatment is used in Paris only because a trained body of gymnasts is not available; the Zander treatment (not, by the way, "unpopular," but nearly unknown, in England) is used for its obvious merits, which Dr. Lambert has, perhaps, not heard of, and skilled gymnasts are afterwards employed for the muscular re-education on which the French lay such stress and which Dr. Lambert seems to have misunderstood. It is sheer nonsense to say the *eau courante* bath is still on its trial, and will be so for two years, when its value has been thoroughly tested in France, and is being now recognised in this country by those who have observed its action. To compare it with massage exposes a degree of want of knowledge truly extraordinary, since its value is

that of a most successful adjuvant to massage. Some of us have been wondering what sort of "expert" advice our overworked War Office has been getting on these serious questions. Here is apparently one of the "experts," and our wonder lessens.

Happily better counsels are beginning to reach the official ear. In July, 1915, four months before the first general announcement of Command Depôts was made (although soon after a further official notice was issued stating that no special treatment was yet available), one of the secretaries went over to Paris to investigate, on behalf of the special committee of the Balneological Section of the Royal Society of Medicine (itself in close touch with the War Office), the remarkable results being obtained at the Grand Palais, and brought back a report which was communicated to the military authorities. In the following February the President of the section went to Paris, and, being afforded special facilities by the French authorities, was able to bring back a very full confidential report on the financial and scientific particulars necessary for the installation in this country on an adequate scale of the French system in order to compare its merits with those of our own procedures. This report was communicated to the War Office at once. Soon afterwards a small installation for officers was privately set up in London, which has been giving excellent results.

There can be no reasonable doubt that there are large numbers of disabled men, up and down the country, for whom an adequate system of physical treatment is not available, and whose disabilities are being allowed to persist in greater degree than would otherwise be the case. The question is now one for the Treasury, the Insurance Commissioners, and, above all, for the public. Are we, or are we not, to be allowed to give a fair trial to a method of treatment which has at least incontestably proved its claim to such a trial? As a student, more than a quarter of a century ago, I remember the lives which were lost by the reactionaries who did not believe in "microbes." Are we to have the lives of our splendid men rendered unnecessarily wretched by needless crippling to please a new generation of reactionaries? I commend Dr. Lambert's report to all who are in doubt.—I am, Sir, yours faithfully,

Exeter, Nov. 6th, 1916.

W. GORDON.

To the Editor of THE LANCET.

SIR,—In an interesting account of the mechano- and electro-therapeutical departments at the Command Depôts and Convalescent Camps given by Dr. Florence Barrie Lambert in your issue of Nov. 4th, she has made one or two statements and implications which we think it our duty to correct.

Dr. Lambert states with reference to a paragraph quoted from a report of a subcommittee of the Committee of Council of the Section of Balneology and Climatology of the Royal Society of Medicine, that "it passes over as practically non-existent the splendid work of the Command Depôts and Convalescent Camps, chiefly because the *eau courante* bath has not been installed broadcast." This is far from accurate. The object of the Committee of Council since its formation in January, 1915, has been to further, by all means in its power, the employment and coördination of all forms of physical treatment for disabled soldiers, whether by means of hydrology, mechano- or electro-therapy, massage, or gymnastics. The committee has never urged the use of one form of treatment to the exclusion of another. The *eau courante* bath was recommended because it had been found a most useful adjunct to massage and mechanical movements, the beneficial effect of which has been shown to be greatly increased by the previous application of the *eau courante* bath. We should also like to point out that neither at Heaton Park Command Depot, nor at the National Orthopaedic Hospital in London, nor at the Red Cross Clinic for Physical Treatment for Officers in London is the Zander apparatus used only for giving *passive* mechanical exercises. The apparatus employed at these institutions and at the Grand Palais Hospital in Paris is used principally for active movements. The "good manual work" which Dr. Lambert so appreciates is very important, but, even when combined with electricity, it cannot replace all other forms of physical treatment.

When the committee was formed there is no doubt that this country had lagged behind both France and Germany with regard to physical treatment, but now, after the lapse

of nearly two years, a great deal of satisfactory work is being done at Convalescent Camps, Command Depôts, and Red Cross institutions in this country. We must not, however, permit ourselves to become self-complacent, but continue to develop, improve, and coördinate all methods of physical treatment, old and new, so that no disabled soldier shall be able to say that he has not had every form of treatment likely to reduce his disability to a minimum on his return to civil life.

We are, Sir, yours faithfully,

London, W., Nov. 6th, 1916.

SEPTIMUS SUNDERLAND,
J. CAMPBELL MCCLURE.

MANUFACTURE OF SALVARSAN PRODUCTS IN ENGLAND AND FRANCE.

To the Editor of THE LANCET.

SIR,—In reply to Captain W. d'Este Emery's and Captain J. Everidge's communication on this subject in your issue of Nov. 4th, I beg to state that since my letters to THE LANCET of April 3rd, May 1st, and May 8th, 1915, I have not drawn renewed attention to my unfortunate experiences with kharsivan for the excellent reason that I decided more than a year and a half ago to abandon its use for ever.

I did in THE LANCET of Sept. 30th last draw attention to the fact that in the space of a few weeks two inquests were reported in the daily papers of fatalities following injections of kharsivan at Guy's Hospital. This can hardly be called my unfortunate experience, but the cases were cited as a justification of the conclusions which I had arrived at, never in the future to employ this preparation.

I am, Sir, yours faithfully,

Queen Anne-street, W., Nov. 6th, 1916.

J. ERNEST LANE,
Major, R.A.M.C. (T.).

To the Editor of THE LANCET.

SIR,—We have read with interest the letter from Captain d'Este Emery and Captain John Everidge, which you publish in your issue of Nov. 4th, and we are pleased to be able to state that our experience of kharsivan is in exact agreement with theirs. In therapeutic effect we regard the British product as identical with the German, and its use has never produced in our hands anything but the most beneficial results.

We are interested to notice that the technique of your correspondents is identical with that which we have followed for several years, and we are confident that were this technique followed carefully by all administrators of salvarsan or kharsivan ill-effects would entirely disappear.

Major Ernest Lane seems to have had some unfortunate experiences. It would be interesting to know if he personally supervises the preparation of all the solutions he uses in administering kharsivan.

We are, Sir, yours faithfully,

Liverpool, Nov. 6th, 1916.

G. STOPFORD-TAYLOR.
R. W. MAUKENNA.

THE ETHICAL STANDARDS OF PANEL PRACTICE.

To the Editor of THE LANCET.

SIR,—Dr. O. Eccles's letter in your issue of Nov. 4th provides food for reflection, for evidently Dr. Mitchell Bruce "knows something" if he said what is attributed to him. The point at the bottom is: the strain on ethical standards which is put on the conscientious panel doctor by the method at present in vogue. A big panel list is a commercial asset, by whatever means obtained, and it is not necessarily the best qualified doctor who gets the biggest panel. There are wheels within wheels, so to speak, and the public are no better judges of doctors than doctors are supposed to be of financial and general business undertakings. Anyway, a big panel list can only be properly supervised by neglecting private work. Since one is not likely to do this, the panel patient puts a great strain on one's ethical standard. He must be disposed of as quickly as possible, but *without offence*, and that for three reasons: 1. He may complain to his Insurance Committee and cause worry. 2. He may cease to recommend his present panel doctor. 3. He may have a family, who are private patients. And so if he alleges he is not fit for work and wants another

certificate, there is a great strain thrown on his panel doctor, and who shall blame him if the temptation is greater than he can bear? Some folk like temptation and court it, and boast how they have resisted it, but there generally comes a time when the resistance gives way. It is a question of human nature and human frailty—and I cannot see where Dr. Mitchell Bruce is wrong in calling attention to the fact, as Dr. Eccles puts it, that with regard to panel doctors "they are tempted by the conditions of panel practice." Contrast the position of the regimental M.O. in taking "sick parade" in the morning, where he sorts out the malingerers from the really sick, oftentimes a difficult task, but he is at a great advantage, being unhampered by temptation as to financial losses or future popularity.

This panel system has caused the medical profession to almost cease to be an "honourable profession," let alone a "noble profession," in the eyes of the public, and the sooner we recognise the fact that it should be carried on by whole-time men, paid by salary, and no temptations to trouble them, the better for everybody—insured, uninsured, and medical men. I write as an old Tory and as the result of experience of panel practice since the commencement of the National Insurance Act: thus only will ethical standards remain what they were in Dr. Mitchell Bruce's early days.

I am, Sir, yours faithfully,

Saffron Walden, Nov. 4th, 1916. JOHN P. ATKINSON, JUN.

THE DIFFERENTIATION OF HEART MURMURS IN SOLDIERS.

To the Editor of THE LANCET.

SIR,—I have read with great interest the letter by Professor David Drummond on the above subject which appeared in your issue of Nov. 4th. I venture to give my experience with regard to the effect of external pressure on functional murmurs, as I am led to believe that many medical men are not aware that steady pressure over the site of a functional murmur at or near the apex will obliterate that murmur, but will not do so in the case of an organic murmur. I have seen quite a number of cases of officers on sick-leave, or invalided out of the service, who have come to me with a history of organic valvular disease, but on examination the murmur has proved to be functional by the pressure test, and has later disappeared on treatment. I do not find it necessary to press in the ribs with the fingers as in Professor Drummond's method, because simple pressure with the bell-piece of the stethoscope has proved sufficient in all cases I have seen. I am particularly interested in Professor Drummond's letter, as I had the pleasure of attending his clinical lectures when I was a student.

I am, Sir, yours faithfully,

Harley-street, Nov. 3rd, 1916. LESLIE THORNE THORNE.

THE TREATMENT OF VENEREAL DISEASES.

To the Editor of THE LANCET.

SIR,—In the annotation entitled "Practical Instruction in the Diagnosis and Treatment of Venereal Diseases," in THE LANCET of Oct. 28th I notice the statement that neo-salvarsan is the only colloid arsenical preparation which can at present be wisely administered intramuscularly. Your contributor evidently overlooked galyl (Bresillon), which is now so largely used intravenously in place of salvarsan. This preparation is also extensively used intramuscularly, especially in France, and with the very best results. It is a very perfect oily emulsion, which, with a little care in technique, can be used with little or no pain. The results are excellent, both immediate, in the clearing up of evident lesions, and ultimate, as proved by the Wassermann test. Personally I have used this preparation in over 400 injections with the best results and without the slightest mishap or inconvenience to the patient.

I am, Sir, yours faithfully,

Leicester-square, W.C., Nov. 2nd, 1916. GERALD DALTON.

CARDIFF MATERNITY HOSPITAL.—Commander Sir Edward Nicholl, who has already subscribed £10,000 to the King Edward VII. Hospital, Cardiff, has given £50,000 towards the Nursing Home and Maternity Hospital. This department of the King Edward VII. Hospital will cost £120,000, of which £80,000 have been subscribed or promised.

The War.

THE CASUALTY LIST.

THE following names of medical officers appear among the casualties announced since our last issue:—

Killed.

Capt. B. J. L. Fayle, R.A.M.C., attached Royal Horse Artillery, was educated at Clifton College and at Cambridge, and qualified in 1913. He held house appointments at the Bristol General Hospital, and joined the R.A.M.C. just prior to the war, obtaining his captaincy in March, 1915.

Capt. T. C. Kidner, R.A.M.C., attached Middlesex Regiment, was a student at the Royal Dental Hospital, London, and at the Middlesex Hospital, qualifying in dentistry in 1912 and in medicine and surgery in 1914. He was in practice at Stoke Holy Cross, Norwich, before the war, and joined the R.A.M.C. in September, 1914, obtaining his captaincy in March, 1915.

Capt. F. N. S. Hitchcock, New Zealand Medical Corps, was a student at St. Thomas's Hospital, London, and qualified in 1907.

Died of Wounds.

Capt. M. J. Rees, R.A.M.C., was educated at the City of London School and at the University of Wales, Aberystwith, and was a student at Guy's Hospital, London, qualifying in 1902. After holding health appointments at Reading and at Aberdare he went to the Local Government Board at Whitehall, and was a medical inspector when he volunteered for the R.A.M.C. He obtained his captaincy in January this year.

Died.

Lieut. F. Whitaker, R.A.M.C., was educated at Cambridge University and at St. Bartholomew's Hospital, London, and qualified in 1903. He had held appointments at the Royal Infirmary, Halifax, and was in practice at Halifax when he joined the R.A.M.C. in October, 1915.

Wounded.

Capt. R. Burgess, R.A.M.C.

Capt. G. L. Jones, R.A.M.C., attached Devon Regiment.

Capt. J. M. Mackenzie, M.C., R.A.M.C., attached Northumberland Fusiliers.

Lieut. G. McI. Dale, R.A.M.C., attached Rifle Brigade.

Capt. H. B. Low, R.A.M.C.

Capt. A. E. Quine, R.A.M.C., attached Middlesex Regiment.

Lieut. R. Younger, R.A.M.C., attached Royal Warwick Regiment.

Capt. N. M. McNeill, Canadian Army Medical Corps, attached Canadian Infantry.

THE HONOURS LIST.

For distinguished service and devotion to duty during the typhus epidemic at Gardelegen Prisoners of War Camp, Germany, during the spring and summer of 1915, when 12 of the 16 medical men of the Allied Forces contracted the disease and two died, the following honours have been conferred:—

C.M.G.—Major P. C. T. Davy, R.A.M.C.

D.S.O.—Capt. A. S. Williams, R.A.M.C., and Capt. A. J. Brown, R.A.M.C., Special Reserve.

MENTIONED IN DESPATCHES.

The names of the following medical officers are to be added to the despatches detailed:—

From General Sir Ian Hamilton, dated Dec. 11th, 1915 (THE LANCET, Feb. 5th, 1916, p. 321): Capt. F. C. Casement, R.A.M.C., Temp. Surg. E. S. Calthorp, R.N., Staff-Surg. A. T. Rivers, R.N., Staff-Surg. C. E. C. Stanford, R.N.

From General Sir Charles Monro, dated March 6th, 1916 (THE LANCET, July 22nd, 1916, p. 163): Capt. A. J. Horne, R.A.M.C., Temp. Hon. Capt. W. T. Thomas, R.A.M.C., Temp. Lieut. H. E. Brown, R.A.M.C. (since relinquished his commission).

From Sir Reginald Wingate, dated August 8th, 1916 (THE LANCET, Nov. 4th, 1916, p. 806): Capt. E. Gibbon R.A.M.C.

Lieutenant-Colonel Gilbert Barling, R.A.M.C. (T.F.), has been appointed a consulting surgeon to the British forces in France.

OBITUARY OF THE WAR.

BLENNMAN BUHÓT GRAYFOOT, M.D. DURH.,
M.R.C.S. ENG., L.R.C.P. EDIN., C.B.,
COLONEL, INDIAN MEDICAL SERVICE.

Colonel B. B. Grayfoot, whose death from illness contracted on active service was reported on Sept. 30th, was son of the Rev. Chrichlow Grayfoot, sometime Chaplain to the Forces in Barbados, and was born in 1860. At the age of 20 he came to this country with a Gilchrist scholarship, and studied medicine at Edinburgh and University College, London, obtaining in due course the conjoint and triple diplomas, and later the M.D. of Durham University. Passing out of Netley into the Indian Medical Service in 1886, he

was for some years in charge of the New Civil Hospital at Karachi, and spent his whole time in the Bombay Presidency, where he was medical storekeeper to the Government until his appointment as A.D.M.S. of the Lahore Division in 1912. On the outbreak of war he went with this division to France, where he was mentioned in despatches and appointed C.B. for his services. In December, 1915, he was transferred to Mesopotamia, where he later became D.D.M.S. For

a period he acted as D.M.S. to the whole of the Tigris Forces. His tireless energy and apparent ability to withstand the rigours of the climate gave place to an attack of jaundice of a malignant variety, from which he died at Alexandria on his way home to England.

Colonel Grayfoot was a man of strong character and genial disposition, trusted by his superiors and looked up to by those of whom he had charge, both natives and Eurasians. It is stated that no one could be awkward or shy in his presence, and many stories are current of his outspokenness on occasions which demanded it. On the occasion of an official visit to a local hospital which was short of necessary funds, the Governor remarked that a certain door wanted new paint to bring it into keeping with the appearance of the rest of the building. Colonel Grayfoot replied: "We had the hospital whitewashed for this visit. Your Excellency, and should have had the door painted if we could, but there wasn't enough money for that!" Colonel Grayfoot will be greatly missed both in India and at home. The portrait which we are able to give of him is from a pencil sketch of the whole of his officers' mess by the French artist Sarut.

DEATHS AMONG THE SONS OF MEDICAL MEN.

The following sons of medical men must be added to our lists of those who have fallen during the war:—

- Second Lieut. J. R. Greathead, Rifle Brigade, sixth son of the late Dr. J. B. Greathead, of Grahamstown, South Africa.
- Second Lieut. G. C. R. Atkinson, East Lancs Regiment, elder son of Dr. T. R. Atkinson, of Chadwell Heath, Essex.
- A. R. H. Chessall, London Regiment, second son of the late Dr. W. Chessall, of Horley, Surrey.
- Second Lieut. H. S. Blair, Duke of Cornwall's Light Infantry, elder son of Dr. C. S. Blair, of Richmond, Surrey.
- Second Lieut. W. H. Dyson, London Regiment, son of Dr. W. Dyson, of Sheffield.
- Second Lieut. A. S. Cleveland, Sherwood Foresters, elder son of Dr. R. A. Cleveland, of Nicosia, Cyprus.
- Corp. A. G. Leeson, Canadian Infantry, only son of the late Dr. A. E. Leeson, of Dorset-square, London.
- Lieut. F. S. Rankin, Canadian Engineers, attached Royal Flying Corps, eldest son of Dr. W. D. Rankin, of Woodstock, New Brunswick.
- Second Lieut. T. Maxwell, Royal Dublin Fusiliers, only son of Mr. P. W. Maxwell, F.R.C.S.I., of Lower Baggot-street, Dublin.
- Second Lieut. T. S. Woods, Royal Field Artillery, eldest son of Sir R. H. Woods, Past President of the Royal College of Surgeons in Ireland, of Merriion-square, Dublin.

CENTRAL MEDICAL WAR COMMITTEE: THE FINANCIAL INTERESTS OF MEDICAL MEN ON SERVICE.

The Central Medical War Committee have drawn up the following procedure which they recommend to the attention of medical men in all localities. Under the procedure the financial interests of medical men on naval or military service would be to some extent protected; loss to them may be inevitable, but much will be saved if the suggestions of the Central Medical War Committee are faithfully followed:—

1. On a new patient presenting himself he should be asked the name of the doctor who last attended him. If his doctor is absent on service and has left a locum tenens an attempt should be made to induce the patient to go to the locum tenens.
2. If the last doctor who attended be on military service it should be explained to the patient that attendance will willingly be given on behalf of that practitioner and on no other terms.
3. Any attendances on behalf of such patients should be carefully and separately recorded and a list of such attendances sent at regular intervals to the representative of the absentee.
4. An attempt should be made to ascertain the fees charged by the absentee, and a charge not less than this should be made on his behalf.
5. Accounts rendered on behalf of the absentee (if sent in by the deputy) should mention the absentee's name, and moneys received should be divided according to the scheme adopted by the Local Medical War Committee.
6. The rule of dividing the fees should apply to all kinds of work. No exception, for example, should be made as regards operations, inquiries, consultations, and anaesthetics, unless some special arrangement has been arrived at as regards particular services by the Local Medical War Committee after consulting the local profession.
7. New patients introduced by the patient of an absentee should be regarded as belonging to the absentee's practice.
8. In cases in which the patient's frequent change of doctor leads to doubt as to who should be regarded as the regular attendant, the absentee should be given the benefit of the doubt.
9. No patient attended on behalf of an absentee should be attended by the deputy for at least one year after the absentee's return.
10. The greatest discretion should be used as to the introduction of a partner or assistant or in commencing a new practice in an area from which men are absent on service.
11. Great care should be taken in the buying and selling of practices. Newcomers to a district should be doubly scrupulous in regard to the practices of absentees, and should at once ascertain and join in any arrangements that have been made for the protection of absent practitioners.
12. The honour of the profession is specially involved where a vacancy occurs through the death of a practitioner on service. Definite arrangements have been made to meet such a contingency in some areas and should be made in all. Every assistance should be given in enabling the successor to the practice to have such a fair start as will entitle the dependents on the practice to expect a fair price for it. The local practitioners should carry out the same procedure with regard to the successor as they had undertaken with regard to the man who has fallen while on service—namely, refuse to attend the patients of the practice except on behalf of the successor, for a period of at least a year after the practice has been taken over.
13. In all cases of doubt as to what is the right course of action as regards an absentee the practitioner should consider what he would like his neighbours to do if he were absent on military service. The Local Medical War Committee or the Central Medical War Committee will always be glad to advise.

PHYSICAL EXAMINATION OF CANDIDATES FOR FLYING SERVICE.

We all admire the work of our aviators, and realise that they must be picked men—how carefully picked few of us have any knowledge. Consequently there is great interest in the account of the measures taken in selecting airmen for the United States Navy and the French Army, which are detailed in the *Military Surgeon* (Washington, D.C.) for October. To begin with, in each case men are required who are ordinarily sound and fit for general service. The United States Navy then requires that their eyesight and hearing shall be fully normal and lays special stress on the absence of middle-ear disease and on careful tests of the sense of equilibration or the power of maintaining balance. The French service makes very minute inquiry,¹ by the help of the D'Arsonval chronograph, into the psycho-physiological aptitudes of candidates, testing their reaction time to auditory and sensory stimuli (must not exceed 0.15 of a second) and to visual signals (must not exceed 0.2 of a second). Emotional tests are also applied, and a candidate is rejected if his respirations are disturbed for more than 1/25th of a second by the unexpected firing beside him of a pistol. So it is said "the heroes of the air are neither neuropathic nor drug users, but calm men of steady hearts, with nerves of steel, strong eyes, and sure hands." In the United States Naval Air Corps the particular after-effect of the use of alcohol, viz., delayed reaction time, causing a lessened ability to act quickly, is a known danger, and its bad effects are prevented by voluntary abstinence.

¹ THE LANCET, March 18th, 1916, p. 633.

HOSPITAL MAGAZINES.—There are many magazines issued for the amusement of the patients and staffs at our war hospitals, among the best being the *Craigleith Hospital Chronicle* and the *Gazette of the 3rd London General Hospital*, the November issues of which have now been published. Both contain pictures and letterpress, humorous and serious, of a creditable standard, and as the profits of the magazines are devoted to providing extra comforts for our wounded soldiers, the publications are deserving of support. The *Craigleith Chronicle* can be obtained at the 2nd Scottish Hospital, Craigleith, Edinburgh, price 6d., and the *Gazette* at the 3rd London General Hospital, Wandsworth, price 3d.

HANDICRAFTS FOR THE WOUNDED.—An appeal signed by Lady Emma Crichton and the Hon. Mrs. Eliot York has been issued on behalf of a fund for supplying materials for handicraft to the wounded in the Royal Victoria Hospital, Netley. For this purpose a sum of £600 is required, and a sale of soldiers' handicrafts will be held in connexion with the fund on Nov. 24th at 19, Grosvenor-square, when H.R.H. the Princess Christian will preside.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—As the result of the Final Examination held from Oct. 10th to 24th the following candidates were among those approved in the undermentioned subjects, but are not qualified to receive the diplomas:—

Medicine.—A. Arias, St. Bartholomew's; H. H. Bailey, L.M.S.S.A. Lond., London; D. J. Batterham, B.A. Cantab., Cambridge and St. Bartholomew's; Margaret Eliza Björkgren, Royal Free; L. G. Blackmore, Middlesex; C. J. L. Blair, St. Bartholomew's; H. J. Blampied, St. Thomas's; C. S. Bluemel, M.A., M.D. Colorado, Colorado University; Hilda Kathleen Brude, Manchester; H. R. Buttery, Cambridge and St. Bartholomew's; P. A. Buxton, B.A. Cantab., Cambridge and St. George's; O. St. L. Campion, Guy's; C. H. Carroll, London; A. A. Cockayne, B.A. Cantab., Cambridge and St. Thomas's; C. J. C. Cooke, University College; G. F. Cooke, St. Bartholomew's; R. N. Cooper, M.B., B.S. Bombay, Bombay University; W. Cramer, University College; H. A. De Morgan, L.M.S.S.A., Middlesex; J. D. Dimock, L.D.S. Eng., Middlesex; J. R. Dingley, University College; H. W. Eddison, B.A. Cantab., Cambridge and Guy's; E. E. Gibb, B.A. Cantab., Cambridge and St. Thomas's; A. Girgis, London; L. B. Goldschmidt, B.A. Cape, King's College; Iris Harding, Royal Free; T. L. Heath, Guy's; N. S. Hewitt, B.A. Cantab., Cambridge and London; L. G. Higgins, B.A. Cantab., Cambridge and St. Thomas's; C. Homi, M.B., B.S. Bombay, Bombay and Middlesex; H. Johnson, L.S.A. Lond., Guy's; E. A. C. Langton, St. Bartholomew's; Hilda Mary Lazarus, M.B., B.S. Madras, Madras University; H. W. Leatham, B.A. Cantab., Cambridge and St. Thomas's; J. B. S. Lewis, B.A. Cantab., Cambridge and St. George's; H. D. McIlroy, B.A. Cantab., Cambridge and London; K. A. I. Mackenzie, B.A. Oxon., Oxford and St. Bartholomew's; Marie Mathilde Alice Moralt, Royal Free; A. H. Morris, Bristol; J. B. Mudge, St. Bartholomew's; Elizabeth O'Flynn, St. George's; A. Orr-Ewing, B.A. Cantab., Cambridge and St. Bartholomew's; W. W. Newton, Birmingham; A. L. Packham, L.D.S. Eng., Middlesex; J. A. Pantun, Manchester; A. A. Prichard, M.A. Cantab., Cambridge and Glasgow; F. H. Smith, M.A. Cantab., L.D.S. Eng., St. George's; N. F. Smith, B.A. Oxon., St. Bartholomew's; R. H. Tasker, Bristol; H. Taylor, Liverpool; S. A. T. Ware, St. Thomas's; A. G. E. Wilcock, Cambridge and St. George's; K. M. O. Woodruff, Guy's; W. G. Woolrich, B.A. Cantab., Cambridge and St. Thomas's.

Surgery.—C. S. Bluemel, M.A., M.D. Colorado, Colorado University; J. Burke, Glasgow and London; A. A. Cockayne, B.A. Cantab., Cambridge and St. Thomas's; A. B. Cocker, L.D.S. Eng., Guy's; M. A. B. Demerdash, University College; H. A. De Morgan, L.M.S.S.A., Middlesex; Frances Jane Du Pré, Sheffield; T. L. Heath, Guy's; M. C. Joynt, Guy's; G. M. Kendall, B.A. Cantab., Cambridge and St. Thomas's; C. F. Kernot, London; E. R. Longstaff, St. Bartholomew's; H. D. McIlroy, B.A. Cantab., Cambridge and London; N. H. S. Maelzer, Guy's; C. J. Pennv, B.A. Cantab., Cambridge and Middlesex; W. M. A. Rahman, University College; M. Shimberg, London; and W. G. Verniquet, B.A. Cantab., Cambridge and St. Bartholomew's.

Midwifery.—J. K. Adhya, M.B. Calcutta, Calcutta and Middlesex; E. G. Anderson, London; E. B. Andrae, London; H. D. Apergis, Guy's; H. H. Bailey, L.M.S.S.A. Lond., London; E. J. Ball, Ph.D. Heidelberg, Bristol; N. A. H. Barlow, Guy's; H. W. Barnes, King's College; D. J. Batterham, B.A. Cantab., Cambridge and St. Bartholomew's; E. V. Beale, B.A. Cantab., Cambridge and London; D. C. Beaumont, Cambridge and London; W. T. Beswick, St. Thomas's; A. O. Bolton and J. E. A. Boucaud, St. Bartholomew's; E. D. Broster, B.A. Cantab., Cambridge and University College; W. B. Buer, Guy's; R. Calvo, St. Thomas's; O. St. L. Campion, Guy's; J. E. Carpenter, London; O. C. Carter, London; D. G. Churcher, St. Thomas's; E. A. Clegg, Middlesex; A. M. Clement, St. Thomas's; R. N. Cooper, M.B., B.S. Bombay, Bombay University; R. S. Corbett, St. Bartholomew's; G. R. Cowie, Middlesex; J. Crestin, St. Bartholomew's; D. R. Curnock, L.D.S. Eng., Charing Cross; G. V. Davies, St. Mary's; S. R. E. Davies, St. Bartholomew's;

P. G. S. Davis, St. Thomas's; L. P. de Abrew, Ceylon and London; H. B. Dodwell, B.A. Cantab., Cambridge and University College; C. T. J. N. Drobig, St. Thomas's; E. F. Fernando, St. Mary's; L. P. L. MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—The next general meeting will be held on Tuesday, Nov. 21st, at 2.45 p.m., at 11, Chandos-street, Cavendish-square, W., Lieutenant-Colonel David G. Thomson presiding. Captain Colin McDowall will read a paper on Functional Gastric Disturbance in the Soldier.

ROYAL SOCIETY OF ARTS.—The sessional arrangements include an opening address (Nov. 15th at 4.30 p.m.) by Dugald Clerk, F.R.S., chairman of the council, on "The Stability of Great Britain"; a paper (Dec. 20th at 4 p.m.) by A. C. Benson, C.V.O., Master of Magdalene College, Cambridge, on "Classical and Scientific Education"; a series of three Howard lectures (Nov. 27th and Dec. 4th and 11th, at 5 p.m.) by John S. S. Brame, professor of chemistry at the Royal Naval College, Greenwich, on "Coal and its Economic Utilisation"; and a series of four Cantor lectures (Jan. 29th and Feb. 5th, 12th, and 19th, at 4.30 p.m.) by Professor A. B. Pite, F.R.I.B.A., on "Town Planning and Civic Architecture." Admission is by ticket.

Parliamentary Intelligence.

HOUSE OF COMMONS.

WEDNESDAY, NOV. 1ST.

Medical Men and the Silver War Badge.

Mr. WATT asked the Financial Secretary to the War Office whether the silver war badge for service was refused to medical men who had served for a year or over in the Royal Army Medical Corps if they had not relinquished their commissions on account of old age, or physical infirmity arising from wounds, or sickness caused by military service; whether he was aware that this regulation worked out unfairly to many medical men who had left the service only on the urgent call of duty to the civilian population who were bound to have some medical attention; and whether he would alter the regulation accordingly.—Mr. FORSTER answered: The silver badge was introduced specifically for distinguishing those who, having served with His Majesty's Forces since August 4th, 1914, have relinquished their commissions or appointments or have been discharged on account of age, wounds, or sickness. It is not a commemorative medal for service during the war. If a medal is granted for the present war, claims of those persons whom the honourable member mentions will be considered with all others who have served in the war.

Medical Appeal Boards.

Mr. ANDERSON asked the Financial Secretary to the War Office how many medical appeal boards had been set up and in what parts of the country; and whether he could state by what means a man who was convinced that he had not received fair treatment by the first medical board could get

in touch with the appeal board and so obtain re-examination.—Mr. FORSTER replied: One special medical board has been set up in London. Men who after being passed fit for service by a recruiting medical board are convinced that they have not received fair treatment can produce evidence to that effect before the tribunal. If the tribunal consider that the men have not been correctly classified by the recruiting medical board and the case goes to the special medical board in London, arrangements are made for the man's travelling and subsistence during the period he is away from home.

Mr. HOGGE: May I ask whether the chairmen of the various tribunals in Scotland have decided that provision could not be made on account of the expenses involved, and under those circumstances could not an appeal board be established in the capital of each country?—Mr. FORSTER: I hope that the answer I have given will remove that feeling.

Medical Arrangements for the Volunteers.

Mr. HOGGE asked the Financial Secretary to the War Office whether there were any medical arrangements for the County of London Volunteers; whether he was aware that accidents occurred during training on Sundays and that the provision of medical assistance was haphazard; whether he was aware that many doctors would be willing to give their services regularly if they were recognised on the old regimental system whereby they could be allocated to the volunteers in their own district; and whether he would devise a system which would utilise such men for a very desirable purpose.—Mr. FORSTER answered: A scheme for the formation of a medical service as part of the Volunteer organisation has been prepared, but certain details remain to be settled. It is hoped, however, that the necessary instructions will be issued very shortly. The considerations referred to in the question have been borne in mind in framing the scheme mentioned above.

Health of Australian Troops.

Mr. LYNCH asked the Financial Secretary to the War Office whether he could state the figures showing the number of deaths from pneumonia during last year among Australian soldiers at Perham Downs; and whether, in view of the difference between the climate of this country and that of Australia, extra precautions would be taken this year to ensure that the health of the Australian troops here should be maintained at as high a level as possible.—Mr. FORSTER said in reply: I have not the figures available, but I can assure the honourable Member that the medical officers, who are themselves Australians, are fully alive to the point and all precautions are being taken.

Infectious Disease and the Discharge of Soldiers.

Sir CHARLES NICHOLSON asked the Financial Secretary to the War Office whether it was the case that no soldier was discharged from the Army, except for tuberculosis, into civil life whilst still in an infectious condition owing to any illness, and particularly any venereal disease; and whether, that was to say, such a soldier was retained under treatment until all danger of infection to others had passed, especially as regards any venereal disease.—Mr. FORSTER wrote in reply: Yes, sir.

T.N.T. Poisoning.

Mr. ANDERSON asked the Home Secretary whether his attention had been called to the inquest on Mrs. Lydia Elizabeth Gibson, aged 24, of Ponder's End, Enfield, who died in St. Bartholomew's Hospital from the effects of T.N.T. poisoning; whether he was aware that it was stated on evidence that the recommendations and precautions against this industrial disease were not being observed at Woolwich; that it was stated by Dr. Collis, the Home Office medical inspector, that as regards the health of women examiners the whole machinery of protection against poisoning had broken down; that the coroner declared that such cases occurred time and again and that it was impossible to find out who was responsible; and whether he would say what further action was to be taken to protect all concerned against the poisonous effect of T.N.T.—Mr. H. SAMUEL replied: The deceased in this case was an examiner in the service of the Inspection Department of the Ministry of Munitions, and was employed by that department at a factory in the north of London, and the usual precautions had not been carried out in her case owing to a misunderstanding as to her position. It was to this point Dr. Collis drew attention at the inquest. No reference was made to the conditions at Woolwich, where, I am informed, the greatest care is exercised, nor was the deceased in any way connected with the Arsenal, but the Inspection Department used to have its headquarters at Woolwich, and its examiners were, and still frequently are, referred to as Woolwich examiners. This no doubt gave rise to the erroneous impression that the Arsenal authorities were concerned in the case. As regards the steps being taken to protect workers against this disease, I would refer the honourable Member to answers to recent questions on this subject.

Physical Condition of School Children.

Mr. ANDERSON asked the Prime Minister whether his attention had been called to the report of Sir George Newman, Chief Medical Officer to the Board of Education, and to his statement that out of the 6,000,000 children in our elementary schools not less than 1,000,000 were so physically or mentally defective or diseased as to be unable to derive reasonable benefit from the education which the State provided; whether he was aware that this state of things was largely due to years of bad housing, insufficient nourishment, and poverty; and whether the Government, in considering after-the-war schemes and policies for the improvement of trade, would also consider schemes of improved social organisation with a view to ridding the country of slums and destitution and placing within reach of all the basis for strong healthy life.—Mr. ASQUITH replied: Yes, sir, these matters are being carefully considered.

Cannock Chase Camps.

Commander WEDGWOOD asked the Financial Secretary to the War Office whether the deaths from pneumonia arising in the Cannock Chase camps during last winter were above the average; whether he had heard complaints as to the condition of the hutments on Cannock Chase; and, if not, would he have an independent inquiry made into the housing conditions on the Chase before the winter came on.—Mr. FORSTER wrote in reply: According to the information in the possession of the Army Council there were only six deaths from October, 1915, to April, 1916, two in February, and four in March. No complaints have reached the War Office as to the condition of the hutments on Cannock Chase.

Hospital Accommodation under Canvas.

Commander WEDGWOOD asked the Financial Secretary to the War Office whether it had now been arranged that convalescent hospitals should be under canvas rather than in huts; what, if so, was the type of tent used; was he satisfied that all such tents were watertight, and also with the class of tent and the flooring of such tents; and, if not, will he send a small committee of responsible civilians to inspect all these convalescent tented hospitals.—Mr. FORSTER (in a written answer) replied: It is necessary to expand hospital accommodation from time to time, and hospitals are sometimes put under canvas in climates where patients and convalescents can remain under canvas in winter. Where this is done proper hospital marquees are provided and extra comforts for the winter are also issued. No complaints of the kind suggested by the honourable Member have been received. I cannot agree to the proposal contained in the last sentence of my honourable friend's question.

TUESDAY, NOV. 7TH.

Military Hospitals in Ireland.

Mr. COOTE asked the Secretary for War (1) whether he could give reasons why the military hospitals at Omagh, Enniskillen, Armagh, and Dundalk were closed and the military patients at those depôts sent to the civil infirmaries in each locality; whether these military hospitals were fully equipped for all their needs; and what was the relative cost of military patients per day in the military and civil hospitals respectively; and (2) whether the assistant deputy of military services, Belfast district, was the authority on all military matters connected with his district; was he consulted before the military hospitals at Omagh, Enniskillen, Armagh, and Dundalk were closed; were they closed with his approval; who was the present deputy of military services in Ireland; and what other posts had he held during the last 12 months.—Mr. LLOYD GEORGE replied: The small military hospitals at Omagh, Enniskillen, Armagh, and Dundalk are unsuitable for the reception of sick and wounded from overseas as they are not equipped for the purpose. They are only used therefore for cases which do not require serious medical or surgical treatment. On the other hand, the county hospitals have experienced surgeons and suitable staff, and have expressed a desire to receive sick and wounded from overseas. All parties have much appreciated the new arrangements, and the scheme is working very satisfactorily at a lessened annual cost to the State. Detailed figures of the relative cost are not available. The authority to decide questions of opening or closing hospitals is the General Officer Commanding-in-Chief, Irish Command.

Nerve-shaken Soldiers.

Colonel YATE asked the Secretary to the Local Government Board whether, in view of the number of men who had been discharged from the Army owing to the effects of uncertifiable nerve strain, any steps had been taken by local committees, acting under the instructions of the Central Statutory Committee, to provide convalescent homes, free from detention or suspicion of connexion with lunacy, to which ex-soldiers of this class might go temporarily, with a view to the promotion of recovery and to linking them up again with their ordinary employment.—Mr. HAYES FISHER replied: The Statutory Committee have advised the local committees that various kinds of treatment are required for

nerve-shaken men. The Statutory Committee have been making careful inquiries into this difficult question, and they have under consideration at the present time a scheme under which appropriate cases would be treated and trained in an institution or institutions in which cases of ordinary wounds and illness other than mental would also be received.

Treatment of Tuberculosis in Scotland.

Mr. MACCALLUM SCOTT asked the Secretary for Scotland whether any steps were being taken to secure throughout Scotland greater progress in combating tuberculosis by any of the following methods—viz., by securing more careful diagnosis of cases in which there was any possibility of tuberculous disease and consequently more general notification in the earlier stages, an improvement of housing conditions, and the establishment and development of after-care committees for the supervision of cases after institutional treatment and for assisting patients to qualify for a suitable change of employment. Mr. TENNANT replied: I recognise the importance of the subject raised by my honourable friend, and have consulted with the Local Government Board for Scotland, who will lose no opportunity of encouraging local authorities, so far as practicable under existing conditions, to deal with the problem of tuberculosis by any available method. I cannot go into greater detail within the limits of a Parliamentary question and answer.

WEDNESDAY, NOV. 8TH.

Medical Students and Military Service.

Answering Captain O'NEILL, Mr. FORSTER (Financial Secretary to the War Office) said: Under instructions issued last August medical students of any year, who have been duly registered in the books of the General Medical Council and who are not fit for general service, are to be relegated to the Reserve and required to continue their medical studies. I have no figures available of the number so released.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

- CULLEN, J. R. F., M.B., C.M. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Acts, for the Alexandria District of the county of Dumfries.
- ELLIOTT, G. C., M.D. Edin., Certifying Surgeon under the Factory and Workshop Acts for the Stafford No. 2 District of the county of Stafford.
- MCKENDRICK, G. B., L.R.C.P. & S. Edin., L.F.P.S. Glasg., Certifying Surgeon under the Factory and Workshop Acts for the Pollokshaws District of the county of Lanark.
- SMITH, MALL, M.R.C.S., L.R.C.P., Senior Obstetric Assistant to the Royal Free Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

When the application of a Belgian medical man would be considered the advertisers are requested to communicate with the Editor.

- BARROW-IN-FURNESS, NORTH LONSDALE HOSPITAL.—House Surgeon. Salary £250 per annum, with board, &c.
- BOURNEMOUTH, ROYAL VICTORIA AND WEST HANTS HOSPITAL (Boscombe Branch).—House Surgeon for six months. Salary £125, with board, &c.
- BRISTOL, CLIFTON DISPENSARY.—Resident Medical Officer. Salary £200 per annum, with furnished house.
- BRISTOL GENERAL HOSPITAL.—Casualty House Surgeon. Salary at rate of £175 per annum, with board, &c.
- BRISTOL ROYAL INFIRMARY.—House Physician. Salary at rate of £120 per annum, with board, &c.
- CHESTER ROYAL INFIRMARY.—House Surgeon and House Physician. Salary £180 and £160 respectively, with board, &c.
- DARLINGTON HOSPITAL AND DISPENSARY.—House Surgeon. Salary £200 per annum, with board, &c.
- DARTMOOR SANATORIUM.—Medical Assistant.
- DERBYSHIRE ROYAL INFIRMARY.—House Physician and Casualty Officer. Salary £220 per annum, with board, &c.
- FOLKESTONE, ROYAL VICTORIA HOSPITAL.—Resident Medical Officer. Salary £200 per annum, with board, &c.
- GREAT NORTHERN CENTRAL HOSPITAL, Holloway, London, N.—House Surgeon for six months. Salary at rate of £100 per annum, with board, &c.
- HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—Assistant Resident Medical Officer. Salary £103 per annum, with board, &c. Also House Physician for six months. Salary 33 guineas.
- LEEDS INDOOR INSTITUTIONS, Beckett-street.—Female Assistant Medical Officer. Salary £225 per annum, with three meals daily.
- LIVERPOOL, BROWNLOW HILL INSTITUTION.—Resident Assistant Medical Officer. Salary at rate of £300 per annum, with rations, &c.
- LONDON HOMOPATHIC HOSPITAL, Great Ormond-street, London, W.C.—Resident Medical Officers. Salary £80 per annum, with board, &c.
- MANCHESTER COUNTY ASYLUM, Prestwich.—Locum Tenens. Salary £7 7s. per week, with board, &c.

- NEW HOSPITAL FOR WOMEN, Euston-road.—Temporary Female Assistant Surgeon for six months. Also Female House Physician, Two House Surgeons, and Obstetric Assistant for six months. Salaries at rate of £50 per annum, with board, &c. Also Anaesthetist. Salary £10 10s. Also Clinical Assistant for Ophthalmic Department.
- NORDBACH-UPON-MENDIP SANATORIUM.—Assistant Medical Officer. Salary £200 per annum, with board, &c.
- PADDINGTON GREEN CHILDREN'S HOSPITAL, London, W.—Temporary Pathologist. Salary £125 per annum, with lunch.
- QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone.—Physician to Infant Consultation Centre.
- ROTTERHAM HOSPITAL.—Junior House Surgeon. Salary as arranged, with board, &c.
- SHEFFIELD, ECCLESALL BIERLOW UNION INFIRMARY.—Assistant Medical Officer. Salary £200, with board, &c.
- SIDMOUTH URBAN DISTRICT COUNCIL.—Medical Officer of Health. Salary £100 per annum.
- SOUTHAMPTON PARISH.—Resident Assistant Medical Officer for the Infirmary, Shirley Warren. Salary £250 per annum, with board, &c.
- STOCKPORT COUNTY BOROUGH EDUCATION COMMITTEE.—School Medical Officer. Salary £300 per annum.
- VENTNOR, ISLE OF WIGHT, ROYAL NATIONAL HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST ON THE SEPARATE PRINCIPLE.—Assistant Resident Medical Officer.
- VICTORIA HOSPITAL FOR CHILDREN, Tite-street, Chelsea, S.W.—House Physician. Salary £200 per annum, with board, &c.
- WARRINGTON, WHITECROSS MILITARY HOSPITAL.—Resident House Surgeon. Residence, rations, &c., provided.
- WEST HAM UNION INFIRMARY, Whipps Cross-road, Leytonstone, N.E.—Resident Assistant Medical Officer. Salary £300 per annum, with usual residential allowances.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Ballindine, Mayo; Slieveagh, Cork; and at Lewes, Sussex.

Births, Marriages, and Deaths.

BIRTHS.

- JEFFRIES.—On Oct. 28th, on H.M. Island Ascension, Jessie, the wife of Surgeon Hugh S. Jeffries, R.N.—a daughter.
- MACFIE.—On Oct. 5th, at Deoban, Colchester, the wife of J. D. Macfie, M.B., Tuberculosis Officer to the Essex County Council, temporary Lieutenant, R.A.M.C.—a son.

MARRIAGES.

- BROSTER—THOMAS.—On Nov. 6th, at Christ Church, Highfield, Southampton, Lennox Ross, Captain, R.A.M.C., to Edith M. V., elder daughter of Mr. and Mrs. D. C. J. Thomas, Elm Croft, Wynn-road, Southampton, and Johannesburg.
- CHARLES—BAILEY.—On Nov. 2nd, at Bulth Well Parish Church, George Frederick Charles, Captain, R.A.M.C., to Dorothy Blake Bailey, daughter of the late John R. Bailey, solicitor, of Mark-lane and Leatherhead.
- MARSHALL—MARSHALL.—On Oct. 17th, at May-street Presbyterian Church, Belfast, Robert Marshall, M.B., Captain, R.A.M.C., to Evelyn Mary, only daughter of William Marshall and Mrs. Marshall, Princeton Villa, Bangor, Co. Down.

DEATHS.

- BETTS.—On Oct. 31st, Dr. R. Sidney Betts, Assistant Medical Superintendent to the Milton Asylum, Portsmouth.
- BOWER.—Killed in action, on Oct. 20th, Lieutenant William C. B. Bower, attached Newfoundland Regiment, R.A.M.C., M.R.C.S., L.R.C.P., late of Torkington House, Stamford, Lincs.
- NETTLETON.—On Nov. 5th, at Winfrith, Folkestone, in his 90th year, Harry Thomas, Fleet Paymaster, R.N., M.R.C.S.
- REES.—Died of wounds, on Oct. 30th, Captain Morgan James Rees, R.A.M.C., M.D. Lond., of the Local Government Board, aged 41.
- WHITAKER.—On Oct. 23th, in hospital abroad, Frederick Whitaker, Lieutenant, R.A.M.C., M.A., M.B., B.Ch. Cantab., in his 42nd year.
- N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

Notes, Short Comments, and Answers to Correspondents.

A PAINTER AND QUACK.

In the Annual Report of the Council of the Royal College of Surgeons of England for 1916 mention is made of the gift to the Museum in the past year by Dr. G. P. Shuter of a pewter enema syringe of peculiar design, "used by the celebrated painter and notorious quack, Dr. Louthembourg." This refers to Philippe Jacques de Louthembourg, who was born at Fulda (Hesse-Nassau) in 1740, and died in London in 1812. His father was a painter and a disciple of Largillière (1656-1746), but wanted his son to follow a military career; his mother, however, favoured the ministry. He followed his own inclination and became a pupil of Charles Vanloo and in his style imitated Berghem and Wouvermans and Salvator Rosa. He was employed by Garrick in 1771 in scene-painting at Drury Lane, and he is credited with the invention of a kind of moving pictures or panorama, called "Eidophysicon." He was admitted to the Royal Academy in 1782. Among his best-known pictures is the "Defeat of the Spanish Armada, 1588," which is in the possession of the Lords Commissioners of the Admiralty and was lent by them to the Royal Naval Exhibition in 1891. As regards his being a quack, the following extract from "Extraordinary Popular Delusions," which has been sent to us by a correspondent, is amusing:—

"Louthembourg the painter and his wife followed the same profitable trade (lectures on animal magnetism); and such was the infatuation of the people to be witnesses of their strange manipulations, that at times upwards of 3000 persons crowded around their house at Hammersmith, unable to gain admission. The tickets sold at prices varying from one to three guineas. Louthembourg performed his cures by the touch, after the manner of Valentine Greatraks, and finally pretended to a divine mission. An account of his miracles, as they were called, was published in 1789, entitled *A List of New Cures performed by Mr. and Mrs. de Louthembourg, of Hammersmith Terrace, without Medicine; by a Lover of the Lamb of God. Dedicated to his Grace the Archbishop of Canterbury*. This 'Lover of the Lamb of God' was a half-crazy old woman, named Mary Pratt, of Portland Street, Marylebone, who conceived for Mr. and Mrs. de Louthembourg a veneration which almost prompted her to worship them. . . . She stated that from Christmas, 1788, to July, 1789, Dr. Louthembourg and his wife had cured 2000 people, having been made proper recipients to receive divine manuductions; which heavenly and divine influx, coming from the *radix God*, his Divine Majesty had most graciously bestowed upon them to diffuse healing to all, be they deaf, dumb, blind, lame, or halt."

In "Old and New London" will be found a reference to Louthembourg, citing Horace Walpole's letter to the Countess of Ossory, July, 1789:—

"Louthembourg, the painter, is termed an inspired physician, and has 3000 patients. His sovereign panacea is barley-water; I believe it is as efficacious as mesmerism. Baron Swendenborg's disciples multiply also. I am glad of it. The more religions and the more follies the better; they inveigle proselytes from one another." "Particular days were set apart and advertised in the newspapers as 'healing days,' and a portion of the house was given up as a 'healing room.' Patients were admitted to the presence of the artist physician by tickets only. In the end the failure of one of Louthembourg's pretended 'miracles' led to his house being besieged by a riotous mob, and he was compelled to make his escape in the best way he could. He however, subsequently returned to his old quarters at Hammersmith, where he died in 1812."

Louthembourg is buried in Chiswick churchyard, where Hogarth's tomb also is. His epitaph is an amazing example of rhodomontade.

VITAL STATISTICS OF MALTA.

Field-Marshal Lord Methuen, Governor of Malta, has reported to the Colonial Office upon the Colony for the year 1915-16. From this Blue-book it appears that the civil population on April 1st, 1916, was estimated at 220,968 as against 218,542 on April 1st, 1915. The birth-rate in the year under review was 30.45 per mille, compared with 31.81 per mille in the previous year; the average birth-rate for the past 12 years was 35.74 per mille. The death-rate in 1915-16 was 23.15 per mille, as against 20.90 in 1914-15, while the average for the past decade was 22.34 per mille. The number of marriages was 1482, as compared with 1121 in the previous year. The general state of health in Malta and Gozo during the year was good. The total number of cases of undulant fever reported from the fleet and garrison was only six; the number of goats and sheep found infected and destroyed during the year was 603 out of a total of 7613 examined. 4514 persons were successfully vaccinated. The death-rate among children under 12 months was 261.55 per 1000 births, as against 242.48 in the previous year. The death-rate of children under five years was 96.70 per 1000 of the population at that age, as compared with 89.19 in the previous year. In 1915-16, 3637 patients were admitted into the hospitals of Malta and Gozo, as against 3407 for the previous year. There were 424 deaths, as compared with 411 in 1914-15. In addition to these,

141,956 persons were attended by the district medical officers at the Government dispensaries or at their own residences, as against 133,078 in the previous year. There were 764 patients in the Lunatic Asylum on March 31st, 1916. The number of admissions during the year was 148; 51 were discharged as cured, 10 as relieved, 12 not improved, 30 not subjects for the asylum; the number of deaths was 58. The inmates in the Leper Hospital increased from 103 on March 31st, 1915, to 110 at the end of the year; the number of deaths was 14. The highest temperature in the shade was 99.5° F. at Casal Zurrioco on August 31st and the lowest 36.5° at Casal Zeitun on Feb. 5th. The mean temperature for the year was 65.4°, as compared with 63.70 in 1914-15.

THE PROLIFICITY OF OPPOSITE TWINS.

To the Editor of THE LANCET.

SIR,—Your recent correspondents on this subject seem unaware of the conclusive investigation carried out by Sir James Simpson and published under the title "On the Alleged Infecundity of Females Born Co-twin with Males" at the end of the first volume of his collected works. Yet his very reason for putting the results of his inquiry on record is that "the evidence that I have obtained upon the topics in view may probably be fortunate enough to save others from expending time and trouble upon the same research."

His conclusions may briefly be summarised in the statement that whereas sterility in such cases is the rule, though not without exception, in the bovine race, it does not hold good amongst any other animals, and that the human "free-martin" is fertile in the same proportion and to the same degree as other women.

I am, Sir, yours faithfully,

MARION B. ANDREWS.

Belfast, Nov. 6th, 1916.

SAUROL.

IN an interesting note on a bituminous deposit found in a mine in Switzerland not far from Lake Lugano, Dr. Louis Merian, of Zürich, calls attention to the important therapeutic qualities of the oil obtained by distilling this shale, which appears to be in no respect inferior to ichthyol. The shale is taken down to a factory in Meride, where it is subjected to distillation. The black bituminous material becomes inflammable when exposed to air and when struck emits a peculiar sulphurous odour. The resulting purified oil contains from 6 to 7 per cent. of sulphur in organic combination and is now on the market for therapeutic use, direct supplies being obtainable from "The Meride and Besano Bituminous Schists Mining Company, Meride, Switzerland." Dr. Merian has studied the effect of sauroil in skin diseases, and reports good results in eczematous and other conditions. He has also employed it for washing out the urethra and bladder with good results. It has also been employed internally in chronic constipation and in all those cases in which ichthyol has given favourable results. As the supply of ichthyol is restricted, the chief source being in the Austrian Tyrol, it is interesting to note that a Swiss product can replace it without disadvantage, and its cost is considerably less. We have received a specimen of the oil, and in appearance it is indistinguishable from ichthyol, while it readily responds to the test for sulphur and shows altogether characteristics consistent with the statement that it is extracted from bituminous schists rich in fossil fish remains.

JOHN PECHEY.

To the Editor of THE LANCET.

SIR,—I am compiling a biographical memoir of John Pechey (1654-1718), the editor of the first English version of Sydenham, and am desirous of obtaining a sight of the following of his works which are absent from the medical libraries:—

"*Promptuarium Praxeos Medicæ*," &c., 1694; 1702 (cum aliis tract.); and 1718, Amst.; 1695, Lipsiæ, 12mo.

"The Whole Works of Sydenham," &c., fifth edition, 1710 or 1711, London, 8vo.

"*Collections of Acute Diseases*," published separately in five parts, 1686-91; and together in one volume, 1691, London, 8vo.

Perhaps one of your readers will be able to help me.

I am, Sir, yours faithfully,

Nov. 6th, 1916.

GEORGE C. PEACHEY.

THE FALLING BIRTH-RATE.

"Disgusted" writes to us of a married couple in his district with four fine children, of whom the man several times during recent years has thrashed the woman without provocation, so that she aborted. After the first assault the local magistrate dismissed the case. "Disgusted" thinks—and we agree with him on the facts as stated—that heavy penalty should have been inflicted.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Tuesday, Nov. 14th.

PATHOLOGY (Hon. Secretaries—G. W. Goodhart, C. Price-Jones): at 5 P.M.

Communications:

Dr. E. W. Scripture: A New Method of studying the Pathology of Speech.

Dr. Crosswell Shearer, F.R.S., and Dr. H. Warren Crowe: The Role of the Phagocyte in Cerebro-spinal Fever.

N.B.—Will members please note that the meeting will be held at 5 P.M. (instead of 8.30 P.M.).

Wednesday, Nov. 15th.

HISTORY OF MEDICINE (Hon. Secretaries—J. D. Rolleston, Charles Singer): at 5 P.M.

Exhibition (at 4.30 P.M.):

Mr. Macleod Yearsley: Document concerning the King's Evil; and other Exhibits.

Communications:

Mr. D'Arcy Power: A Revised Chapter in the Life of Dr. William Harvey.

Dr. James Rae: The Medical History of the Exiled Stuarts.

Thursday, Nov. 16th.

DERMATOLOGY (Hon. Secretaries—J. E. R. McDonagh, Henry MacCormac): at 5 P.M.

Exhibition of Cases (at 4.30 P.M.).

Friday, Nov. 17th.

OTOLOGY (Hon. Secretaries—E. D. D. Davis, Somerville Hastings): at 5 P.M.

Cases and Specimens:

Will be shown by Mr. W. M. Mollison, Dr. H. Banks Davis, Mr. Somerville Hastings, Mr. E. D. D. Davis.

N.B.—If other members desire to show cases will they please communicate at once with Mr. E. D. D. Davis, 39, Wimpole-street, W.

ELECTRO-THERAPEUTICS (Hon. Secretaries—E. P. Cumberbatch, Robert Knox): at 8.30 P.M.

Discussion:

On "The Treatment of War Injuries by Electrical Methods."

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—8.30 P.M., Discussion on Epidemic Nephritis (opened by Capt. Langdon Brown, R.A.M.C.(T.). Followed by Sir W. Osler, Bart., Lieut. J. S. Dunn, R.A.M.C., Mr. W. H. Jessop, Dr. S. West, Mr. J. F. Adler, and Dr. T. J. Horder.

ROYAL MICROSCOPICAL SOCIETY, 20, Hanover-square, W.

WEDNESDAY.—8 P.M., Paper:—Dr. C. Singer: The Microscopic Work of the Accademia dei Lincei.

CHILD STUDY SOCIETY LONDON, Royal Sanitary Institute, 90, Buckingham Palace-road, S.W.

THURSDAY.—6 P.M., Discussion:—Experiments in Hand-writing in Schools—Dr. C. W. Kimmins: A Further Account of Speed Tests in Manuscript Writing. Papers:—Mr. W. Scutt: The Artistic Aspect of Manuscript Writing; Mr. J. W. Samuel: Manuscript Writing in a Central School; Mr. A. Sinclair: Manuscript Writing in a Boys' Elementary School. (The papers will be illustrated by lantern slides.)

SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, Cavendish-square, W.

FRIDAY.—5.30 P.M., Papers:—Dr. H. Bayon: The Development of Pathogenic Properties in Protozoa, with Special Reference to the Herpetomonid Group.—Dr. C. H. Treadgold: A Note on the Eggs of the Liver Fluke *Clonorchis sinensis*, var. *Minor* Verdun and Bruyant, 1908.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East.

TUESDAY AND THURSDAY.—5 P.M., Fitz Patrick Lectures:—Dr. W. H. R. Rivers: Medicine, Magic, and Religion. (Part II.)

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

Course of Lectures on the Anatomy of the Human Body, for First aid and Ambulance Students:—

MONDAY.—5 P.M., Lecture VI.:—Prof. A. Keith: The Spinal Cord and Nerves.

WEDNESDAY.—5 P.M., Lecture VII.:—Prof. A. Keith: The Structures concerned in Shock.

FRIDAY.—5 P.M., Lecture VIII.:—Prof. A. Keith: The Anatomy of Wounds received in Warfare.

Anatomical Preparations and Specimens used for illustration will be on exhibition in the Theatre from 3 P.M. to 5 P.M. on each lecture day, and between 10 A.M. and 5 P.M. in the Hall of the Museum on the following day.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simson: Diseases of Women.

TUESDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical

and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Dr. Simson: Diseases of Women.

THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Gray: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Simson: Gynecological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics.—10.30 A.M., Surgical Out-patients (Mr. E. Gillespie). 2.30 P.M., Medical Out-patients (Dr. T. R. Whiphram). Gynecological Out-patients (Dr. Banister). 3 P.M., Medical In-patients (Dr. R. M. Leslie).

TUESDAY.—2.30 P.M., Surgical Operations (Mr. Carson). Clinics:—Medical Out-patients (Dr. A. G. Auld); Surgical Out-patients (Mr. Howell Evans); Nose, Throat, and Ear Out-patients (Mr. C. H. Hayton). Radiography (Dr. Metcalfe). 3.30 P.M., Medical In-patients (Dr. A. J. Whitting).

WEDNESDAY.—Clinics.—2.30 P.M., Throat Operations (Mr. C. H. Hayton). Children Out-patients (Dr. T. R. Whiphram); Eye Out-patients (Mr. R. P. Brooks); Skin Out-patients (Dr. H. W. Barber). 5.30 P.M., Eye Operations (Mr. R. P. Brooks).

THURSDAY.—2.30 P.M., Gynecological Operations (Dr. A. B. Gilles). Clinics:—Medical Out-patients (Dr. A. J. Whitting); Surgical Out-patients (Mr. Carson); Radiography (Dr. Metcalfe). 3 P.M., Medical In-patients (Dr. R. M. Leslie). Special Demonstration:—Dr. R. M. Leslie: Selected Medical Cases.

FRIDAY.—2.30 P.M., Surgical Operations (Mr. Howell Evans). Clinics:—Medical Out-patients (Dr. A. G. Auld); Surgical Out-patients (Mr. E. Gillespie); Eye Out-patients (Mr. R. P. Brooks).

THE THROAT HOSPITAL, Golden-square, W.

MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.

THURSDAY.—5.15 P.M., Clinical Lecture.

CHADWICK PUBLIC LECTURES.

TUESDAY (at the Norwich Museum).—3 P.M., Dr. C. Porter: The Health of the Future Citizen—Lecture III., The Child (illustrated with lantern slides).

INSTITUTE OF HYGIENE, 33-34, Devonshire-street (Harley-street), W.

TUESDAY.—4 P.M., Lecture:—Lady Barrett: Venereal Disease—its Racial Effects.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

The following journals, magazines, &c., have been received:—Canadian Practitioner, Therapeutic Gazette, Dublin Journal of Medical Sciences, Revue de Chirurgie, Philippine Journal of Science, Archives de l'Institut Pasteur de Tunis, Nordiskt Medicinskt Arkiv, British Journal of Dental Science, British Dental Journal, Homoeopathic Recorder, American Journal of Public Health, Biochemical Journal, Medico-Legal Journal.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

Offices: 423, STRAND, LONDON, W.C.

MANAGER'S NOTICES.

ALTERATION OF INLAND SUBSCRIPTION RATES.

INCREASED war expenses and cost of production necessitate an increase in the subscription rates.

The revised Inland Subscription rates are:—

| | |
|---------------------|---------|
| One Year | £1 10 0 |
| Six Months | 0 16 0 |
| Three Months | 0 8 0 |

The revised rates for the Colonies and Abroad (thin paper edition) are:—

| | |
|---------------------|---------|
| One Year | £1 12 6 |
| Six Months | 0 17 6 |
| Three Months | 0 8 9 |

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed) London County and Westminster Bank, Covent Garden

Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET OFFICES, 423, Strand, London, W.C.

ADVERTISEMENT RATES.

Y.—Yost Typewriter Co., Lond.; Mr. C. G. Young, Bettisfield.

An Inquiry INTO

THE NATURAL HISTORY OF SEPTIC WOUNDS.

By KENNETH GOADBY, M.R.C.S., L.R.C.P.
LOND., D.P.H. CANTAB.,

LATE HUNTERIAN PROFESSOR, ROYAL COLLEGE OF SURGEONS OF
ENGLAND; HONORARY BACTERIOLOGICAL SPECIALIST, ROYAL
HERBERT HOSPITAL, WOOLWICH; LECTURER ON BACTERIOLOGY,
NATIONAL DENTAL HOSPITAL, ETC.

(A Report in Three Sections to the Medical Research Committee.)

SECTION III.¹—TISSUE REACTIONS.

In the previous two sections of the present report I have attempted to collect certain facts relating to Sinuses and Sinus Formation and Vaccine Therapy, reserving the consideration of Tissue Reactions, both general and local, to the present and concluding section.

Many of the present observations are concerned with the phenomena of sinus formation, and in addition complement the conclusions reached after a critical survey of controlled vaccine therapy—namely, the utmost importance of the adoption of immunological methods as an essential and urgently necessary concomitant in the general principles of treatment of the wounds of war, not only as a palliative in the earlier febrile stages, but experimentally and clinically shown to be the intrinsic therapeutic and orderly complementation of the normal defensive processes whereby injured tissues re-establish their integrity and defeat the invasion of infecting micro-organisms.

BLOOD EXAMINATION IN SEPTIC WOUNDS.

In Table VII. I have collected the figures of the total and differential blood counts in certain cases of wound infection. The clinical type of case is indicated, and the day of disease upon which the examination was made is given. The majority of the patients were severely ill at the time the blood was examined. A case of acute streptococcal infection contracted by a nurse in attendance on septic wound cases and two cases of cerebro-spinal meningitis are included for comparison.

Acute gas gangrene.—Cases Nos. 1 to 9 and 37 were clinical gas gangrene. In Nos. 1, 3, 9, and 37 amputation was performed. No. 1 was a fatal case. The blood was taken immediately after amputation of the leg and shows very little departure from normal; a slight increase of leucocytes is noticeable; there were no changes in the red cells and no polikytosis. Case No. 2: Blood obtained on the day before amputation; blebs were present on the skin and contained *B. perfringens*; the leucocyte count is practically normal. In Cases Nos. 4 and 6 secondary hæmorrhage had occurred, which complicates the blood enumeration from the point of view of gas gangrene. Case No. 6 had a very extensive flesh wound; the red cell count was abnormally low in this case as well as in Case No. 5, but the leucocyte count was high. The differential count shows polymorphonuclear leucocytosis. Case No. 9, a severe compound fracture necessitating amputation followed by chronic tetanus, showed considerable leucocytosis, mainly polymorphonuclear; the amputation was performed on the tenth day and the blood count was made five days later. In all 10 cases, *B. malignant oedema*, *B. perfringens*, streptococci, staphylococci and members of the coli group were isolated; in Nos. 1, 2, 4, and 10 *B. perfringens* in enormous numbers was found in the infected tissue.

Severe septic wounds.—Cases Nos. 10, 11, 12, 13, 15, 16, 18, 19, 20, 28, and 34 were without clinical gas gangrene, but had gas bubbles in the pus together with *B. malignant oedema*, *B. perfringens*, *B. Hibler*, *B. proteus*, *B. coli*, streptococci and staphylococci. In case No. 18 the blood count, made after secondary hæmorrhage, showed a great diminution in the red cells count, definite leucocytosis, and a white cell ratio of 1:122. The differential count, taken in conjunction with the total white cell count, shows the

increase to be general, with a slight increase in polymorphonuclears. In Cases Nos. 12 and 34 counts made on the fifty-sixth and twenty-fourth days respectively (both cases were still very ill) showed myelocytes in the blood; these were not seen in the other cases. The total increase in the white blood cells in the average septic wounds is below 20,000 per cubic millimetre.

Streptococcal septicæmia.—In Cases Nos. 17, 23, 27, and 34 streptococci were obtained from the blood during life. In Case No. 34 *B. perfringens* was also obtained. Of these four cases three died and one recovered (34). In Case No. 23 the polymorphonuclears were 89 per cent. In Case No. 34, which recovered, the differential count shows first a normal polymorphonuclear proportion, followed by an increase in their ratio as the case recovered. *Perfringens* and streptococci were isolated from the wound, but *B. malignant oedema* was not found.

Streptococcal infection, blood culture negative, wound positive.—Cases Nos. 14, 21, 23, 25, 30, 35, and 36. The blood enumeration was made somewhat late in Cases Nos. 14, 25, and 35. Case No. 14 gave an almost normal count with the exception that myelocytes formed 2 per cent. of the differential count. Case No. 30 was an industrial accident, a crush of the upper part of the thigh with extensive skin necrosis and foul odour. *B. perfringens* was found in the undermined skin and subcutaneous tissue. Case No. 24, prolonged sepsis commencing with paratyphoid fever and later running on to perineal abscess. The blood count in this case gave the lowest of any of the cases examined. Case No. 33, an instance of streptococcal infection occurring in a nurse, shows the diminution in the hæmoglobin from 90-50 in the course of nine days, with a sharp fall and then a slow rise of the leucocyte ratio. The differential counts give a marked increase of polymorphonuclear cells.

Other Cases.—Nos. 31 and 32 are blood examinations and differential counts in acute and convalescent cerebro-spinal meningitis. Case No. 29 was a proteus infection in which *B. proteus* was obtained both from the knee-joint wound and the urine. This case shows a low polymorphonuclear count and an increase of leucocytes; the other case showing a low differential count being Case No. 11, a case of gas gangrene without constitutional disturbance.

Emery suggests that the leucocyte count in cases of malignant oedema may be 40,000 or more. In only one case in my series, Case No. 5, was the leucocyte count above 40,000; in this case practically all the cells were polymorphonuclears. The case recovered. In Case No. 2 the blood was taken during the acute stage of infection, but the leucocyte count was not above normal. Case No. 1, a fatal case, blood taken at amputation of thigh, the total leucocytes had only reached 12,000. It is only in the recovered case or during recovery that the full leucocytosis is established.

It seems from a survey of Table VII. that some information is to be obtained from the total and differential blood counts in differentiating gas gangrene and streptococcal septicæmia. Early leucocytosis with a considerable increase of the polymorphonuclear cells is suggestive of the streptococcal infection rather than of commencing malignant oedema, and in view of the histological findings it is probable that the leucocytosis occurring in the later stages of gas gangrene and during recovery is related to the secondary coccal infections of the wound rather than to *B. perfringens*, &c. The degree of anæmia is more pronounced as far as the hæmoglobin is concerned, and a sharp fall in hæmoglobin, with an increase in polymorphonuclear cells in the differential count, points to coccal, perhaps streptococcal, infection. The presence of myelocytes and other signs of tissue irritation occur in late stages of wound infection.

Emery also states that a left deviation of Arneth's count is observed in cases of gas gangrene. In Table VIII. are given eight cases of Arneth's count in acute sepsis. The case numbers given in Table VIII. correspond to Table VII. It will be seen that the left deviation is pronounced in certain cases, more especially in Cases Nos. 12, 14, and 27. In these three cases prolonged sepsis had occurred, and in No. 27 the condition of the patient was desperate. A case of cerebro-spinal meningitis is appended for comparison.

On staining by Giemsa's method or Pappenheim's panoptical method (a combination of Jenner and Giemsa) in blood from cases of severe wound infection, a large number of polymorpho-

¹ Sections I. and II. were published in THE LANCET of July 15th (p. 89) and Sept. 30th (p. 585), 1916, respectively.
No. 4864.

basophilic, are to be found, but the general appearance of the polymorphonuclear cells is the most striking, suggesting considerable cell degeneration; probably, notwithstanding the high total of the leucocyte count, a number of the polymorphonuclear cells in the circulating blood are aberrant, and it is questionable if their phagocytic activities remain normal.

HISTOLOGICAL EXAMINATION OF SEPTIC WOUNDS.

During the course of the investigations attention was frequently directed towards the tissue reactions occurring in the wounds, partly by clinical phenomena and partly by observation during surgical operations. Some reference to these tissue reactions has been made from time to time in the preceding sections, and I now propose to detail the more important observed facts which have a direct bearing on the after-history of a wound. It is not possible at the present moment to give a complete survey of the tissue changes taking place in all classes of wounds; time has not allowed examination of all the available material, and consideration of many of the interesting side issues must be reserved until a later date. Certain general facts, however, have come to light, and amongst them some having a practical bearing on clinical treatment. The tissue reactions may be divided into two main categories:—A. The local reactions in the wounded tissues engendered (1) by the impact of the missile, (2) by the bacterial flora developing within the wound. B. The general or systemic reactions produced as a result of changes in the wound itself, resulting in alteration in the blood and symptoms of disease in parts of the body remote from the wound.

I have already noted in passing, and it is essential to recapitulate briefly before proceeding to the description of the histological changes which have been met with, certain facts which mark off the wounds of war from the wounds met with in civil hospital practice and everyday civil life. Practically every gunshot wound, with the possible exception of simple in-and-out wounds of the flesh, show—(a) deep tissue laceration, together with what may be termed *molecular disturbance* and disintegration of the surrounding area; (b) anaerobe infection grafted on to a wound of irregular and radiating form. Some years ago Professor Boys used to exhibit in the course of certain popular lectures, photographs of bullets striking and passing through a pane of glass; the photographs showed curious waves caused by the disturbance of the air radiating from the point and butt of the bullet. Similar waves were seen radiating in all directions from the glass at the moment of impact, and after the bullet had passed through the glass, each particle of the splintered material flying off at various angles possessed a similar V-shaped wave. Now when a bullet strikes flesh or bone the enormous energy in foot pounds possessed by the bullet (circa 200 foot pounds at 200 yards range) must be absorbed by the tissue in the immediate vicinity, splinters of bone are driven off, each with their own degree of

momentum, and the total energy possessed at the moment of impact by the bullet is thus distributed over a wide area, and each particle driven off the bone produces some degree of wound of the soft tissues. Such an illustration, though imperfect—the photographed waves of the bullet and fragments of glass are due to alteration in the density of the air—assists one to visualise the energy absorbed by the tissue when struck by a high-velocity projectile. Much more damage is caused than usually appears on mere inspection or even prolonged surgical examination of such wounds, and I believe that this generalised but microscopic tissue damage is one of the primary factors in the production of gas gangrene.

When a shrapnel ball or shell fragment is removed from a wound, more particularly from bone, a piece of clothing is frequently found driven into the tissue in advance of the metal fragment, and histological examination of wounds shows that, in addition to pieces of clothing, fragments of skin and surface epithelium are also driven in, and at times take root and become grafted on to the deeper tissues. Histological examination of sections of recent wounds frequently shows fragments of skin which have become adherent to the surrounding connective tissue; whether such grafts may eventually prove dangerous only the future can tell.

I have already pointed out in the section on Chronic Sinuses that I have succeeded in isolating anaerobic bacteria from a large series of sinus cases many months after the original wound was inflicted and in numerous cases in which the external wound had completely healed. There is little doubt that the disruption of the tissue radiating from the vicinity of the injury is in a great measure responsible for the persistence of anaerobe bacteria; their method of entrance requires little explanation, clothing and fragments of epithelium driven into the wound produce direct inoculation; thus, in a recent case of a simple in-and-out wound without bone injury mud from the trenches was present on the skin of the thigh near the entrance wound. The mud was scraped off (nearly a gramme was obtained), and from it both *B. perfringens* and *B. malignant* oedema were obtained on cultivation.

Chronic Anaerobic Infection.

Conditions for anaerobic development and persistence in a wound are ideal, and the following case is typical of such persistence.

Vaccine Case No. 19, Table VI. (Section II.), showed spore-forming organisms in the pus films, and *B. malignant* oedema and *B. perfringens* were isolated in pure cultivation. Five days after wounding portions of the broken muscular fibre, comminuted bone, radius and ulna, were excised at time of operation. A further examination of this case was made on the 232nd day; a small sinus was persistent which passed downwards to a cavity in the ulna. X ray photographs showed a small sequestrum lying in the centre of the cavity, surrounded by a great deal of loose callus. The sequestrum was removed and cultures made from it and fragments of the callus. *B. malignant* oedema and *B. perfringens* were recovered.

Histological Examination.

I. *Specimen from operation on fifth day.*—Bone, fibrous and connective tissue, and muscle were found inextricably mixed; here and there scattered throughout the tissue were areas of cell proliferation, in which a considerable number of cocci, staphylococci, and streptococci were seen; a few large bacilli were scattered amongst the cocci, but their numbers were small in comparison with the coccal infection. (Fig. 7.) This area of cell proliferation was mainly situated towards the free surface of the tissue and corresponded to the internal surface of the actual wound cavity. In the deeper layers of the mass cell reaction is nil; bundles of muscle fibres are observed, which have lost their striation. The connective tissue between the bundles is swollen, oedematous, stains badly, while long cracks and mechanical separation of muscle fibre and connective tissue are seen in all directions. The connective-tissue cells stain badly, and a number of greenish-yellow patches and stippling are partly fat globules and partly represent the remains of nuclei. Hematoxylin and eosin fail to show any living nuclei in these regions. A great difference is seen between the inner and the external parts in sections stained by Gram's method. In the depths a considerable number of Gram-positive bacilli and few cocci exist, in the outer layers few Gram-positive bacilli and many cocci are found. In the deeper layers, although the bacteria are mainly confined to the supporting tissue of the muscle bundles, some are seen lying in spaces in the muscular tissue itself, at times between

the individual muscle fibres. (Cp. Fig.) Some of the bacilli stain irregularly, with the curious granular appearance characteristic of *B. perfringens*, but in other areas bacilli with subterminal spores are seen in small groups. The organisms for the most part are arranged with their long axes parallel, and although the structure of the capillary walls is indistinct, the whole appearance suggests that the organisms have travelled along the capillary channels. In some situations the muscular tissue is entirely disintegrated and large masses of bacteria are found, but these areas are few in number, especially when compared with sections presently described, obtained from cases of acute gas gangrene.

It will be seen from the foregoing that both bacteriological and histological examination demonstrated the tissue infection with organisms of two classes, *aerobes* more or less confined to the superficial areas, *anaerobes* mainly present in the depths. The tissue damage evidently contributed in some measure to the bacterial distribution. The description of the section is typical of a large number of wounds investigated. One is struck in examining such cases with the paucity of tissue reaction to the anaerobe infection on the one hand and the tissue necrosis on the other, especially when compared with streptococcal or other usual types of infection.

II. *Specimen of callus and sequestrum removed at operation on 232nd day.*—The sections of the callus stained by hæmatoxylin and eosin showed much loose bony formation and areas of connective-tissue spaces filled throughout with proliferating cells; the nuclei throughout stained normally; in the bone Haversian canals are seen in active formation. Here and there spaces are found throughout the callus in which secondary degeneration has taken place; few nuclei are visible, but fibrous stroma is everywhere evident. The nuclei of portions of the adjacent tissue show vacuoles, are ill-defined; many have disappeared. The areas of secondary degeneration are small and do not make up any considerable proportion of the tissue; in some parts the newly-formed and irregular bone is apparently dead. The cellular elements immediately surrounding the structureless areas stain very deeply, owing to the presence of a mass of polygonal and multinucleated cells, the nuclei of which are in a state of active mitosis; polymorphonuclear cells are to be seen amongst them as well, some with cytoplasm staining brightly with the eosin.

Sections stained with Gram-Weigert.—The clear spaces noted in the hæmatoxylin- and eosin-stained specimens are found to contain bacteria. The islands of structureless bone, surrounded by inflammatory cells, contain numbers of streptococci in long curled chains, the cell proliferation passing right up to the edge of the streptococcal infection. The cells, especially the polymorphonuclears, are seen to contain numerous englobed organisms, mostly diplococci, but a few chains of streptococci are seen. The streptococcal infection is for the most part confined to the free borders of the tissue—namely, that forming the internal wall of the cavity. The sequestrum also showed active cell proliferation, with a similar mass of streptococci at the free borders of the tissue. The clear spaces noted in the hæmatoxylin-eosin specimens and in which the nuclei were unstained, contained a few Gram-positive bacilli; the numbers were small and no bacilli were observed in the tissue cells surrounding. No actual spores were seen, the actual number of Gram-positive anaerobes was small, a fact confirmed by the bacteriological examination; for although both *B. malignant oedema* and *B. perfringens* were recovered subsequently, three or four days elapsed before the bacilli appeared in the cultures.

The histological appearances observed in this sinus and sequestrum are illustrative of numerous similar cases examined. The chief emergent fact is the association of tissue regeneration and tissue degeneration in the same district of the wound, a circumstance closely related to the clinical course observed in many compound comminuted fractures. The anaerobic persistence, associated with minute areas of degeneration in the immediate vicinity of the organisms, to some extent explains the intractability of the "sinuses" and furnishes a clue to "flares" following sinus operations. These facts also support the procedure suggested by Captain C. W. Rowntree of using a tourniquet to facilitate the examination of deep sinus cavities and the removal of minute sequestra, each of which if left in the wound may act as a fresh focus of infection. Lazarus-Barlow,¹ in dealing with reaction to causes of inflammation, says: "But though it may be broadly stated that when the irritant is living the presence of numerous cells at the part is most obvious the statement is not entirely correct." He also further points out how frequently coincident destruction and repair may be observed in tissues infected with micro-organisms. However, although considerable controversy exists as to the source of

the phagocytes which destroy the organisms in an infected area there is general consensus of opinion that phagocytosis is the ultimate process of destruction of the invading bacteria in wounded tissue, yet even after long intervals of time have elapsed from the date of wounding, patches of tissue without phagocytic reaction are invariably found, such tissue stains badly, is apparently undergoing digestion, and is usually found in the vicinity of Gram-positive anaerobic bacteria. On the other hand, on examining a number of sections of wound tissue, areas are found in which phagocytic activity is a prominent feature, and bacteria of the anaerobic variety may be seen engulfed by a number of the cells.

Sir Almroth Wright,² in his lecture before the Royal Society of Medicine, has shown that the *B. perfringens* is readily phagocytosed *in vitro* by polymorphonuclear leucocytes, and d'Este Emery,³ in a modification and amplification of the method suggested by Sir Almroth Wright, gives some interesting details of the conditions determining phagocytosis of *B. perfringens in vitro*; he also suggests that a toxin is elaborated by the organism inducing negative chemiotaxis. On the other hand, a number of observers, amongst whom may be quoted Muriel Robertson⁴ and Taylor,⁵ have found considerable difficulty in obtaining a toxin from *B. perfringens*, while Dale and Barger⁶ only found ammonia from cultures of *B. malignant oedema*. There is reason to suppose, as was suggested at the conclusion of Section I. of my report, that the biological activity of the anaerobes might be of more importance than their infectivity. *B. perfringens* readily produces acid from glucose, from inositol, and from other carbohydrates, and there is not a little evidence to suggest that the curious and rapid changes in muscular tissue in the neighbourhood of perfringens infection is related to the biological production of acid rather than to the liberation of true toxin. I shall recur to this point after discussing the histology of acute gas gangrene.

Acute Gas Gangrene.

The following case is illustrative of the type of acute gas gangrene met with during the inquiry.

The case was admitted on the fifth day with shrapnel wounds of both legs and left upper arm; a large piece of shrapnel was lying embedded in the left calf in close proximity to the upper end of the tibia; there was no bone injury. The radiograph suggested a large amount of gas in the region of the wound, apparently in the subcutaneous tissue and separating it from the muscles and fascia. The leg was amputated through the middle of the thigh. Subsequent dissection of the leg confirmed the diagnosis of gas infiltration; the whole of the subcutaneous tissue from just below the knee-joint to within three inches of the ankle-joint on the posterior surface of the leg, was separated from the muscular layer by the development of large quantities of gas; incision of the leg resulted in the escape of gas in considerable quantities. The muscular tissue was not deeply penetrated, but the surface of the gastrocnemius was undergoing surface digestion; in the immediate region of the wound there was no deep infiltration of the muscle visible to the naked eye. The subcutaneous tissue spaces formed by the gas pressure were occupied by areas of semi-fluid blood clot and hemorrhagic exudation of recent origin; there was no smell. At the upper and lower extremities of the area of gas infiltration, penetration of the subcutaneous tissue by an irregular line of pus formation was found, extending along the intermuscular planes. There was no naked-eye appearance of gas in this region, and the tissues appeared normal in colour and were undigested, but on either side of the area of pus formation beyond the gas-affected parts the subcutaneous tissue, when incised, gave off a quantity of yellow fluid. This yellow fluid contained a number of globules, which on staining by Sudan III were found to be fat. The fluid itself was quite clear, free from cells on microscopic examination, and rapidly stained any linen or dressing material bright yellow. I have already noted this yellow staining as associated with *B. malignant oedema*. On the addition of a small amount of blood to a portion of the fluid, complete clotting occurred in about five minutes, but the fluid itself did not undergo spontaneous coagulation. The subcutaneous tissue from which this fluid exuded was much more yellow than the unaffected areas, and by making a longitudinal section of the skin and subcutaneous tissue throughout the length of the amputated limb, transition from gas infiltration through areas of pus formation, yellow and oedematous and finally normal subcutaneous tissue could be easily traced. Similar phenomena have been observed in all other cases in which immediate dissection of the amputated limb was performed.

Unfortunately, on the day subsequent to the amputation of the thigh, the wound in the left upper arm broke down with severe secondary hæmorrhage, necessitating ligation of the third part of the axillary artery. Within 15 hours of the ligation the internal surface of the upper arm had undergone degenerative changes; the muscles were soft and diffident, particularly the biceps; the skin was dead and in ribbons, the fœtor extremely pronounced, and emphysema was found in the muscle. Amputation was accordingly performed and immediately upon amputation the arm was dissected. A similar condition to that observed in the leg was found; the area of gas infiltration and subcutaneous hæmorrhage was found to extend down the forearm to within two inches of the wrist-joint, but in this area there was no penetration of the muscular tissue. The subcutaneous tissue in the lower part of the upper arm and the upper part of the lower arm was œdematous and exuded yellow fluid which did not clot spontaneously but coagulated on the addition of a small amount of blood; no cells were seen in this fluid, but fat globules were found floating on the surface. The humeral biceps muscle was the one principally involved and was found more affected than the gastrocnemius. On separating the muscles the whole of the biceps was found infiltrated and emphysematous; a portion cut off floated in water and crepitated like a piece of lung. The other muscles of the upper arm were unaffected except superficially where they were in contact with the biceps. The deltoid was quite normal on its outer side and contracted sharply when incised.

In a previous section of the report I have drawn attention to the yellow staining found upon dressings under certain circumstances, and have pointed out that this curious yellow may be found occasionally in cultures on egg broth containing *B. malignant* œdema. The stain sometimes resembles that caused by iodine and was at first attributed to it, but the above description points to tissue disintegration as the source of this yellow-stained lymph, and its presence may be regarded clinically as a sign of progressive tissue destruction calling for careful surgical consideration. Some of the fluid was collected and further examined in the laboratory.

Slight coagulation occurred on boiling, but the coagulum formed was small and the whole fluid did not clot. The portion to which blood had been added after standing for 15 hours separated into loose clot and yellow clear fluid, similar to that obtained from the tissue.

Spectroscopically no absorption bands were seen, and the fluid which separated off from the clot did not contain hæmoglobin bands. On shaking with chloroform the yellow colour passed into the chloroform; this gave no spectroscopic information. On the addition of amyl-alcohol no extraction of colour took place, but general precipitation occurred. The precipitate gave Millon's reaction. On addition of dilute acid to the original fluid a white, somewhat sticky, precipitate formed, insoluble in alkali. Sodium hydrate produced no precipitate in the original fluid. The precipitation of this fluid by dilute acids will be referred to subsequently.

A bacteriological examination was made of the arm and leg; cultivations from every source, including the pus at the spreading edge of the gangrenous area, gave *B. perfringens* and *B. malignant* œdema in addition to streptococci and Gram-negative bacilli. *B. malignant* œdema and *B. perfringens* have been recovered from all the cases I have examined.

Microscopical examination of the muscular tissue attacked by acute gas gangrene gives an extraordinarily striking picture, especially when compared with that of a normal muscle or inflammation of muscle due to other forms of bacterial infection. The outstanding feature in acute gas gangrene, foreshadowed by the examination of chronic anaerobic infection, is the absence of cellular reaction. The actual form of the muscular tissue is not greatly altered at the commencement—that is to say, the muscle bundles remain in their supporting network and in transverse sections are abnormally definite but still show striation. The following description taken from the case of acute gas gangrene described above is typical of the histological findings in all the cases I have investigated.

Portions of the gastrocnemius near the wound and the humeral biceps were removed for histological examination. The portion of the biceps floated when placed in Müller's solution. The specimens were stained by hæmatoxylin and eosin and Gram-Weigert. Both transverse and longitudinal sections show muscle bundles widely separated from one another, the connective-tissue spaces between the main fasciculi are widely dilated, stretched, and in most instances only a small quantity of tissue debris is left which remains attached to the muscle bundle. (Fig. 8.) No cell nuclei are seen; some parts of the fibrous tissue contain granular masses

and granules suggesting disintegrated nuclei; the striation of the muscle bundles has disappeared. The individual muscle fasciculi do not all stain to the same degree, and here and there, scattered throughout the section, spaces are seen representing the position of a muscle bundle which has undergone liquefaction. No individual cells can be made out, no leucocytes and no connective-tissue corpuscles are apparent. Under higher powers many of the muscle bundles are eroded, their edges irregular and diffident, and here and there in the less affected muscles a faint trace of the original striation is observed; many are split into their ultimate fibres.

On examining the Gram-stained specimens with high magnification the whole of the interstitial spaces are found packed with a mass of Gram-positive organisms (Fig. 8), together with some smaller Gram-negative rods; no phagocytosis is seen. The organisms are not free, but are in the tissue spaces and clustered along the lines of the capillary vessels in the supporting tissue; in many instances the network of this tissue can only be traced by the arrangement of the bacteria. Very few organisms are to be found inside the muscle bundles, but this invasion takes place at a later stage, and here and there large spaces are seen in the interior of the muscle bundles containing bacilli resembling *B. perfringens*. In a few instances definite penetration of the muscular tissue is observed, organisms passing inwards from the disrupted edge of the muscle.

The picture is in certain particulars comparable with that of chronic gas gangrene already described, the infection and disruption of the tissue being only one of degree. Where the process has been in operation for rather longer, attempts at repair are found at the edges of the infection. The muscle tissues have lost most of their nuclei in the infected areas, but just outside this area the nuclei are deeply stained and can be traced around the muscle bundles. As the infected area is gradually approached the muscle bundles are found partially digested, staining is unequal, and some fragmentation has taken place, best seen where the muscle is cut longitudinally, proliferation of the connective-tissue corpuscles has commenced, and here and there the proliferation has progressed so far that whole tracts of muscle bundles have been replaced with round-cell infiltration of the usual type, suggesting that the partially dead muscle is being rapidly cleared away. Amongst the cells in the outer limit of the infiltration phagocytes are seen containing bacilli and other cells containing Gram-positive granules, evidently the semi-digested protoplasm of *B. perfringens*. The bacterial flora of this part consist mainly of cocci mixed with a few Gram-positive and a few Gram-negative bacilli. Clinically the gastrocnemius muscle was only slightly affected; the emphysema had not spread throughout the muscle from which the section was made. The appearance of the section suggests that commencing infiltration was in progress, but at the same time defensive tissue reaction was getting the upper hand in the area under examination.

Spore-forming organisms are not always found, but in some cases they are present in considerable numbers. Fig. 9 shows a portion of muscle from such a case; a crack, probably caused by gas pressure, is seen extending across the upper part of the field, and another commencing split is seen in which are a number of spore-forming organisms of the malignant œdema type. The granular stippled appearance is also well shown. In other portions of this section areas are seen occupied by organisms without spores and staining with the curious Gram-granular effect so often seen in *B. perfringens*. Fig. 10 is such a field obtained from the same case. Figs. 11 and 12 are from the extreme limits of the gangrenous process; Fig. 11 showing a small ruptured vessel the walls of which are outlined by the mass of Gram-positive bacilli adhering to them, a clear gas space exists between the vessel and the muscle tissue in which numerous phagocytic cells are seen packed full of Gram-positive bacilli; a good many free unphagocyted organisms are also seen in the intercellular spaces. The lower part of the photomicrograph shows a tissue space probably due to gas splitting.

Fig. 12 is a photograph of the same area but under a lower power than Fig. 11. This section shows the relationship of the area of tissue reaction to the source of infection, a small vessel the wall of which has given way. The wall of the vessel is clearly outlined by a dark line which, on examination with a high power, is seen to consist of a mass of Gram-positive bacilli adhering to the vessel walls. The connective-tissue spaces are seen on the other side in the vicinity of the blood-vessel. These specimens are stained by Gram-Weigert. In the hæmatoxylin-eosin specimens the nuclei stain deeply, and many well-defined mitoses may be seen. A little below this part, not shown in the photograph, the tissue is undergoing coagulation necrosis, and the nuclear staining is indistinct. Attempted repair has therefore progressed to a certain point and has then ceased, some influence having destroyed the tissue vitality.

A small portion of subcutaneous tissue was removed from the extreme limits of the gangrene of this case. Pus

formation had commenced, and although no actual discharge or abscess cavity had formed the tissues were impregnated with milky purulent fluid which microscopically showed numerous phagocytic polymorphonuclear cells. The tissue in this region was 8 inches distant from the actual site of injury. A large amount of fibrous tissue was in course of formation; organisms, many of them partially digested, were found within the cells; the majority of these organisms were cocci. Bacilli were few in number.

Summary of the Pathological Histology of Gas Gangrene.

Throughout the greater part of the affected tissues the cells are dead, the nuclei have disappeared, and no trace of defensive tissue reaction is to be found. Scattered through the supporting fibrous and cellular tissue are enormous numbers of Gram-positive bacilli, mainly confined to this tissue but also invading the muscle bundles. The destruction of the tissues is so complete that it might be compared to the devastated and blackened country over which a prairie fire has passed, leaving but a few withered and shrivelled tree trunks in its wake. In the region of the actual wound where the primary infection commences, cocci and Gram-negative bacilli in addition to the anaerobic Gram-positive bacilli are found; the cell reaction is intense, and the destroyed tissues are in an active stage of repair by round-cell infiltration.

The mere occlusion of the circulation, either by thrombosis or by gas pressure, is hardly sufficient to determine the extraordinary disappearance of cell structure in a comparative short time—10 to 15 hours—and the phenomena point overwhelmingly to the generalised action of some rapidly diffusing protoplasmic poison.

In a recent communication Cuthbert Wallace⁷ gives a very valuable description of gas gangrene as seen at the casualty clearing stations. He cites a case in which microscopical in addition to bacteriological examinations were carried out by Captain J. W. McNee, Captain E. Roberts, and Lieutenant Dunn. Sections of the affected muscles showed that the fibres had lost their transverse striation, the muscle substance was broken up in transverse plates or presented longitudinal markings as if painted with a coarse brush. Between the fibres, which were obviously separated from one another, were bacteria in varying quantities in the inter-fibrillar spaces. There were some polymorphonuclear leucocytes. Wallace makes a number of extremely important observations; he says that the lesion in its early stages is apparently longitudinal, running up and down the muscles. Muscles and groups of muscles are involved while others escape. There is little tendency for the infection to pass from one muscle to another. Crepitation is apparently a late phenomenon. Gas crepitation develops in the later stages of the disease. Wallace quotes the paper I have already referred to by Mullally and McNee,⁸ in which secondary gas gangrene occurred at the site of hypodermic injections. A similar case occurred in my own series, in which gas gangrene developed in the track of saline infusion, performed in the chest wall during amputation in a case of gas gangrene of the thigh.

Wallace further states that "many men who die of the effects of gas gangrene in the clearing stations die before there is any marked suppuration; it may be that the supuration and involvement of the fascial planes are seen after the patients have left the front, being a late manifestation of the disease." This supposition is borne out by my own observations made upon cases which have been incised for gas gangrene in France and hospitals in this country. The cases already quoted in which suppurative areas were found at the extreme limits of the acute gangrenous process may be taken as one type of sequelæ; the other type, surgical wounds, in which gas bubbles are found in the pus, local spread of the original mixed suppurative process, and radiating areas of tissue-necrosis (incipient gangrene), from which members of the anaerobic group of bacilli can be isolated. Cases have been seen which had been operated upon for gas gangrene in France; profuse discharge of pus was present, and in the pus both *B. perfringens* and *B. malignant oedema* were isolated without difficulty, showing that whilst the actual organisms of gas gangrene are still present in the wound, the surgical expedient of wide incision had limited the development of further spreading gangrene. In Tables V. and VI. (Section II.) the bacteriology of this type of case is given and the relative proportion of the species of bacteria is seen to be the chief difference between acute gas gangrene and chronic or subacute anaerobic inflammation.

Wallace suggests that the infection travels inside the vessels just before or after the circulation has ceased, the open ends of the vessels on the infected wound being the starting point. There is no doubt that this is the right explanation in the early stage. The description of the histology given above and the illustrations, Figs. 11 and 12, support the view that blood infection is the important channel of dissemination. The rapidity with which the disease spreads, the intimate relation of the organisms to the blood-vessels, and the fact that they are found within the vessels, demonstrate that they have entered before coagulation occurs. The occasional exacerbation of symptoms of gas gangrene after "subsequent" surgical interference confirms the view that the open ends of the vessels are the portal of entrance. In the chronic or recurrent cases the local development of gas may split and open the tissues, thus allowing the organisms to enter the vessels. There is another and probably a more important factor in the spread of infection which has support from clinical and bacteriological evidence—i.e., the elaboration of digestive enzymes in the affected areas. We have evidence in the first place that recurrent secondary hæmorrhage takes place from a wound; this point has already been dealt with in Section II., Table VI., and also in Section I. in discussing sinus formation. Secondly, the bacteria isolated from the wound in such cases are organisms whose proteolytic activity is demonstrable—i.e., *B. malignant oedema*, *B. proteus*. Further, after many months the tissue from the depth of a sinus has been shown to contain the *B. malignant oedema*, and histologically patches of tissue-necrosis have been observed.

Histological evidence, clinical evidence, and bacteriological evidence therefore may be correlated, and point to tissue digestion as of paramount importance in furthering the spread of gas gangrene. Cuthbert Wallace's observation that single muscles and groups of muscle tend to be affected suggests the infection of a common blood-supply. Emery found that in order to facilitate the development of *B. perfringens* the addition of chalk is of considerable assistance, and that in tubes to which chalk had been added the development of the organisms was accelerated, and that in such tubes the amount of free acid in the medium was small. He also points out in discussing the question, "Is *B. perfringens* actually the cause of gas gangrene?" that the organism, though found mixed with other bacteria in the superficial layers, is present in increasingly great numbers as the deeper layers of the infection are approached. My own

DESCRIPTIONS OF ILLUSTRATIONS.

(I am indebted to my friend, Mr. Cyril Hill, F.R.M.S., for the photographs.)

Fig. 7.—*Localised gas gangrene*.—Compound comminuted fracture of ulna and radius tissue removed at operation five days after injury. Evil-smelling black pus containing many gas bubbles. The tissue shows heavy coccal infection (top right hand) at part corresponding to wound cavity, various large bacilli are seen penetrating the deeper structures, which have lost most of their nuclei. Both *B. perfringens* and *B. malignant oedema* were isolated. Gram-Weigert $\times 1000$.

Fig. 8 (from Case 1, Table VII.).—*Acute gas gangrene*.—Humeral biceps 15 hours after ligation of axillary artery. Section of affected muscle. The muscle bundles are seen widely separated and all connective-tissue structure has disappeared. Large numbers of *B. perfringens* are seen lying in the spaces between the bundles, which in places are undergoing digestion. Stained Gram-Weigert $\times 500$.

Fig. 9.—*Acute gas gangrene*.—Compound comminuted fracture of femur, much oedema, gas infiltration slight but present, a crack probably caused by gas pressure is seen extending across the upper part of the field, and from it another commencing split is seen in which are a number of spore-forming organisms of *B. malignant oedema* type. The muscle from which this section was cut showed general blackening (malignant oedema reaction). Stained Gram-Weigert $\times 1000$.

Fig. 10.—*Acute gas gangrene*.—Extensive flesh wound of thigh; no bone injury. Similar case to Fig. 7, but this section was obtained at a distance from the gas-infiltrated area; the muscle was red, Wallace's "red death" (*B. perfringens* reaction). The remains of a few nuclei are seen and many Gram-positive bacilli. Stained Gram-Weigert $\times 500$.

Fig. 11.—*Acute gas gangrene*.—Deep flesh wound of buttock. Subcutaneous and muscular tissue at the extreme limit of the gas infiltration of the thigh, near knee. The upper part of the figure is the subcutaneous tissue; between it and the muscular tissue is a crack due to gas infiltration. A small vessel, the walls of which are rendered distinct by the Gram-positive organisms adhering to the walls, lies just above the crack, and at two points, one to the right and another to the left, the vessel wall has ruptured. The muscular tissue is full of phagocytes. Stained Gram-Weigert $\times 250$.

Fig. 12.—*Acute gas gangrene*.—A portion of the muscular tissue from the same case more highly magnified showing the commencing disruption of the muscular fibres and the large Gram-positive organisms (*B. perfringens*) within the polymorphonuclear cells. Stained Gram-Weigert $\times 500$.

FIG. 12.

observation on the histology of gas gangrene given above entirely confirms the presence of the anaerobes in greatest numbers in the deeper parts of the tissue (see Figs. 8, 9, 10, 12). Emery also calls attention to the original experiments of Welch—namely, that if an animal is infected with *B. perfringens*, killed, and then incubated the bacilli grow with great rapidity throughout the body, but are found in greatest numbers and produce the largest amount of gas in those organs which are richest in sugar.

Emery lays down as one of the important factors, if not the most important, in the spread of gas gangrene the inhibition of leucocytic activity by the toxins produced by the organisms. Taylor,² on the other hand, regards the gas fragmentation of the tissues as the chief cause of dissemination, and suggests the gas pressure occludes the circulation in the tissues and further assists the organisms to diffuse. He says: "No cases of subcutaneous infection without previous muscular invasion have been seen among the patients. The pathology is therefore chiefly limited to muscle destruction." He notes a sweet odour of the gas escaping from the wound and that it explodes if lighted with a match. My own observations upon the tissues are substantially in agreement with those of Taylor, but I am inclined to interpret the phenomena somewhat differently, to regard the gas infiltration as a stage of the tissue alteration and coagulation necrosis as the primary lesion. Mullally and McNee and Taylor note the presence of polymorphonuclear leucocytes as usually occurring in the depths of the infection, but in those cases I have examined, as noted above, the outstanding feature of the deep areas of infection is the absence of any cell proliferation. (Fig. 8.) Taylor's illustration of muscle debris with gas bubbles does not show any active cell proliferation. Taylor says the bacilli are massed around the external portions of the muscles. This feature is characteristic of certain muscular fibres, and is, I believe, the second step in the infection, and it is presumably in such areas that rapid gas-formation occurs. The fulminant cases of gas gangrene are accompanied, as the name implies, by enormous development of gas, often taking place with such extraordinary rapidity that the phenomenon has been aptly described as explosive.

General Summary of the Various Ascertained Facts Relating to Acute Gas Gangrene.

- (1) The syndrome is rapid, at times explosive, in onset.
- (2) The histology of the tissues points to widespread and rapid destruction which the occlusion of tissue circulation alone seems inadequate to explain.
- (3) Anaerobic organisms are always demonstrable, *B. perfringens* especially in the areas of extreme gas formation, but *B. malignant* oedema may usually be found on careful examination.
- (4) In 75 per cent. of septic wounds uncomplicated with acute gas gangrene, anaerobic bacteria similar morphologically and culturally with those of gas gangrene are demonstrable.
- (5) The toxicity of *B. perfringens* and *B. malignant* oedema cultures is invariably low even when isolated from fulminant cases.
- (6) Phagocytosis of *B. perfringens* is observed both *in vitro* and *in vivo*.
- (7) The two organisms found in gas gangrene differ in their biological activities. *B. malignant* oedema is essentially proteolytic. *B. perfringens* is essentially a fermenter of carbohydrate.

A critical consideration of the various phenomena relating to the gas production by anaerobic bacteria, especially *B. perfringens*, therefore appears to promise the most likely explanation of the tissue destruction and the march of the disease.

The production of gas by *B. perfringens* upon milk often occurs with extreme rapidity, and is apparently related to some physical balance which having been attained the generation of gas occurs with violence, the milk clot becoming torn and disintegrated; so rapid is the associated production of acid concomitantly that the organisms quickly die off and subcultures from the milk tubes are frequently negative. This phenomenon of sudden gas formation is also exhibited by other anaerobic bacteria; thus, if a suitable medium of magnesium, calcium chloride, &c., in distilled water is prepared, and pure cellulose in the form of filter paper added and a small quantity of Thames mud, the flask

placed under strictly anaerobic conditions and incubated, gas is developed and the filter paper disintegrated. Some time usually elapses before the gas is given off in any quantity, the latent period being up to three days, but when the equilibrium point is reached the action is frequently so violent that the cotton-wool plug may be driven out of the flask. The phenomenon, due to anaerobic cellulose fermenters, is strikingly similar to the sudden development of gas in cases of gas gangrene, and, moreover, again suggests that anaerobic fermentation may have a "critical point" below which activity is slow. Further research in this direction is in progress.

Wallace, in discussing the theories of the disease as suggested by Taylor and Emery, adopts the *via media*, that both views—namely, the primary toxin view of Emery and the gas fragmentation suggested by Taylor—are both of importance in the production of infection. On the other hand, Taylor calls attention to the fact that the production of toxin by the *B. perfringens* is extremely small; this is the experience of all who have attempted to extract the toxin from *B. perfringens* cultures. Emery agrees that the amount of toxin produced is extremely small, but by using 48-hour culture with the addition of chalk the fluid produced inhibition of leucocyte activity, but he says even then all cultures did not give satisfactory results.

Analogy to other infections has led to the postulate of a "toxin" as the cause of tissue destruction in gas gangrene, notwithstanding the fact that the toxicity of broth cultures *in vitro* is extremely small. On the other hand, Dale and Barger have shown that *Vibrio septique* produces toxic material when grown upon muscle, but they showed that this toxic agent was probably free ammonia. Now, when carbohydrates are fermented with gas production various products are formed, among which organic acids and alcohol are paramount. *B. perfringens* is a carbohydrate fermenter, producing acid as well as gas, as may be demonstrated in milk and also in *meat cultivations*. The red colouration of cooked meat produced by *B. perfringens* in the laboratory is exactly similar to the red colouration seen in affected muscles in man and aptly termed by Wallace "red death." The reaction of the *red meat* in culture tubes is acid; so, too, is the *red muscle* in gas gangrene. The muscle sugar and glycogen of the tissues is obviously the substrate from which the gas is derived, and the fermentation of this substrate with gas formation must be associated with a corresponding development of acid, the tissues in cases of gas gangrene giving a distinct acid reaction. Sir Almoth Wright, quoted by Emery, is of opinion that there is a marked decrease in the alkalinity of the blood in cases of gas gangrene.

I have already pointed out above that the tissue changes in gas gangrene are extremely rapid, that tissue coagulation and disappearance of the nuclear staining precede the evolution of gas, and that the destruction of the tissue is more rapid than can be ascribed to the cessation of circulation by gas pressure. The appearances certainly suggest a toxic agent, but the consensus of opinion derived from animal experiment negatives the presence of a highly virulent and diffusible toxin.

Is there any other product of the biological activity of *B. perfringens* which is produced in considerable quantity which can account for the widespread damage? Gas has been suggested, but with inositol and glycogen present in the muscle gas means carbohydrate fermentation, and carbohydrate fermentation with gas production entails production of acid. *B. perfringens* not only produces gas from cooked meat *in vitro*, but turns the meat a curious red, and this red meat gives an acid reaction. The muscles in the vicinity of gas gangrene before they have become riddled with gas have a curious red colour (Wallace's red death). This colouration and that of the meat in the culture tubes are identical. Further, if the acid formed in a culture is neutralised as soon as it is formed, the organisms continue to ferment the substrate with the production of gas until all the available carbohydrate is exhausted; if, therefore, the acid produced from the carbohydrates in the tissues be neutralised as it is formed, continuous fermentation and continuous gas production will take place, there will then be little or no free acid in the tissues; physiologically the fixation of acid by the tissues is possible.

One other point may be adduced. The tissue fluid escaping from the limits of the gangrenous process has been

demonstrated to be precipitated with weak acid, and it is not improbable that the progressive spread of the gangrenous area may be accelerated by precipitation of the oedema fluid in the tissues themselves through the action of the acid produced by carbohydrate fermentation.

It is not suggested that no toxin is produced by *B. perfringens*, although so far no highly virulent one has been obtained, but it seems reasonable to correlate the demonstrable acid production of the organism with the tissue changes found in gas gangrene rather than to postulate a toxin which experiment has so far failed to demonstrate.

CONCLUSIONS.

The conclusions which may be broadly stated arising from the facts scheduled in the third section of my report relate mainly to certain tissue reactions against bacterial infection, and may be briefly summarised:—

(1) That the energy dissipated in the tissues from projectiles produces changes in a wider area than that immediately lacerated by the projectile itself.

(2) That the cellular activity promoting repair in the affected areas proceeds concomitantly with degenerative processes; with the degenerative processes are associated anaerobic bacteria, *B. perfringens*, *B. malignant* oedema, and possibly *B. Hibler* IX. type.

(3) That there is direct histological evidence of tissue digestion, in addition to necrotic changes due to traumatism or coagulation owing to interference with circulation. Evidences of degenerative tissue changes are found in tissue removed from wounds at long periods after the original infection of the wound.

(4) That acid production by anaerobic bacteria of the *perfringens* class is an important factor in the determination of clinical gas gangrene.

(5) That the general blood reaction in the direction of leucocytosis is more related to infection with the pathogenic cocci than the anaerobic bacilli.

In the three sections of the present report an attempt has been made to correlate certain facts obtained in the course of an inquiry as yet uncompleted, and this, the concluding section, is perhaps more an indication of the lines upon which research is proceeding. The examination of the tissue reactions in the wounds has been found to be in close agreement with the general bacteriological details given in the previous sections. The bacteriological data as to the organisms occurring in the depth of the sinus have been confirmed by direct examination of the tissue concerned. The bacteriological evidence of sequestered organisms in the sinus walls of "flare" cases also receives striking confirmation from the histological examination. The evidence adduced confirms the opinion previously expressed that the organisms remaining in the tissue retain their activity and potentiality for disease. Theoretically there is further evidence that the use of vaccine therapy of appropriate antigen is of advantage in combating the infections. Sir Almroth Wright,¹⁰ in his address on wound infections, says:

"None the less we shall do well carefully to consider in connexion with the employment of vaccines in the treatment of imperfectly drained wounds certain questions. It is clearly a matter for consideration whether—despite the fact that the output of pus from the wound is not diminished—there may not be some useful clinical result from the vaccines. In short, it is not unreasonable to think that the antiseptic vaccines might aid the surgeon in his conservative surgery, and might enable him to hold on longer when trying to save a limb.

Sir Almroth Wright thereafter points out the importance of drainage in wound treatment.

The histological evidences I have advanced strongly support the conclusions of the second section of my report and the opinion of Sir Almroth Wright cited above. No drainage in the ordinary sense of the term can easily affect the contorted intricacies of a sinus passing first of all into bony tissue and thereafter radiating in several directions; it is in this type of wound, or rather sequelae to a wound, that the bacteria are found lodged in the tissues, partially shut off from the action of the living cells. Operative interference sets them free; they may, and do, reinfect the surrounding areas, and to raise the patient's resistance to such disability is clearly a therapeutic step of supreme importance.

A NOTE ON THE VALUE OF VACCINE THERAPY IN THE TREATMENT OF SEPTIC GUNSHOT WOUNDS.

VIEWED FROM A SURGICAL ASPECT.

BY R. H. JOCELYN SWAN, M.S. LOND., F.R.C.S. ENG.,
CAPTAIN, ROYAL ARMY MEDICAL CORPS; SURGICAL SPECIALIST,
ROYAL HERBERT HOSPITAL, WOOLWICH; SURGEON TO THE
CANCER HOSPITAL, S.W., ETC.

DURING the last two years a very large number of cases of septic gunshot wounds have been under my immediate care, and as some of these have recently been brought into prominence in a series of articles in THE LANCET by my colleague Mr. Kenneth Goadby, under the heading of "An Inquiry into the Natural History of Septic Wounds," it has occurred to me that a short note from the surgical aspect of these cases might prove of benefit to my surgical colleagues who are engaged in similar work to myself in base hospitals.

I must confess that when first I commenced the treatment of these septic cases in September, 1914, I, in common with many surgeons, was inclined to look upon vaccine therapy as of a very minor importance, but after a few months' work with Mr. Goadby became convinced of the value of appropriate vaccines, and now seek his assistance in the treatment of my cases. In our earlier work the routine bacteriological examination of the wounds showed that the large majority were infected with multiple organisms, but nearly all contained a bacillus of the coli or proteus group, pyogenic cocci and anaerobic gas-forming organisms, and it was not long before we recognised that it was the admixture of the proteus and the cocci which paved the way for the anaerobe to invade the tissues in the immediate proximity of the wound and cause the breaking-up of the muscle tissue and the partial digestion which is now recognised in these wounds. Following up this line, I have now had a large number of my cases treated with a mixed vaccine of proteus and streptococcus, and can without any hesitation say that the treatment has to a large extent assisted the other methods of treatment carried out on ordinary surgical lines.

To such an extent have I modified my former views as to the value of vaccine in these cases, that I now direct that every case arriving from overseas with a septic wound should receive an initial dose of a mixed polyvalent vaccine of proteus and streptococcus until the true bacteriology of the individual wound can be worked out and before any surgical measure, other than freely incising the wound to secure adequate drainage, is adopted. This may appear at first glance as a "shot in the dark," but it is only in a comparatively few cases that a mixed infection containing both proteus and streptococcus will not be found, and I would make a note of the necessity of making an examination of both the superficial and the deep aspects of the wound, for we have found so frequently that the deeper part of the wound only will give the true indication of anaerobic activity. The future course of vaccines naturally depends upon the examination revealed in the individual wound, when appropriate combinations can be given.

In some cases operative interference of some sort is necessary as an urgent measure before vaccine therapy can be given, and it is in these cases that the operation is so frequently followed by pyrexia to 102° to 103° F. for from

Continued from preceding column.

Note.—A supply of the sensitised antiseptic vaccine, referred to in the report, is available, and on application will be sent, with full instructions for administration, to any medical officer in charge of hospitals treating septic gunshot wounds.

24-48 hours, whereas similar cases in which vaccines have been used usually show no pyrexia even when anaerobic gas-forming organisms were proved to be present in the depth of the wound. In the large majority of cases arriving from overseas I contend that no operation should be performed without the knowledge of the interior of the wound afforded by a thorough radiographic examination, particularly as regards bone injury and the presence of metal fragments, and it is just this time that is so valuable in an attempt to immunise patients against the proteus and streptococcal infection that, in my opinion, it should be done in all cases.

I have found the greatest value of vaccine therapy in the treatment of complicated septic fractures of long bones and of fractures which open into joint cavities. In the treatment of septic compound fractures I now make a routine practice of giving a preliminary dose of polyvalent vaccine (proteus and mixed streptococci), and then after two or three days freely open the wound to secure adequate drainage, approximating the fragments and only removing those fragments which are undoubtedly completely separated, at the same time taking advantage of the opening of the wound to obtain further bacteriological examination. Extension apparatus of various types or splints suitable to the individual fracture are applied, but should the resulting position of the fragments prove on further radiographic examination to be unsatisfactory, I have no hesitation, after a further few doses of specific vaccine, in securing the bone fragments in apposition by means of silver wire or even bone plates in the presence of sepsis, and can now look back on a series of cases in which not only have limbs been saved, but bones in good alignment and functional use. Further, the result as regards sinus formation and necrosis of fragments of bone in the seat of fracture has been more appreciably lessened in those cases in which vaccines have been used than in those in which exactly similar surgical measures were employed without the assistance of vaccines.

In the treatment of septic gunshot fractures which involve a large joint, I am sure that vaccine therapy holds an important place. I have been so disappointed in the past with the ultimate result obtained in these cases, where the resulting immobility of a joint such as the elbow or the shoulder so seriously affects the wage-earning capacity of the patient, that I have, after an immunising course of vaccine, proceeded directly to excise the joint in the presence of sepsis, leaving the cavity freely drained and following with an appropriate specific vaccine. In these cases I have been able to obtain a freely movable and serviceable limb, and a much better result than after excising a fixed joint after the wounds have healed, when the tissues around the joint are so matted by the long-continued suppuration. I hope to be able to refer more fully to the treatment of septic fractures and to fractures involving joints in a future article.

Another feature which has impressed me very forcibly is the freedom from secondary hæmorrhage in cases treated with a polyvalent proteus and streptococcal vaccine. Whereas before its use secondary hæmorrhage was not uncommon in septic wounds, I have had no case under my care in which it has occurred where vaccines have been employed. In my earlier work with Mr. Goadby I kept two wards of cases untreated with vaccine in order to compare the results obtained in wards in which vaccines were used and it was in those cases not treated with vaccine that secondary hæmorrhage occurred. Surely this cannot be a coincidence where exactly similar surgical measures were adopted, but must in some measure be influenced by the vaccine; it seems probable that the control of the proteus and streptococcal infection arrests the digestive action in the tissues of the anaerobic coexisting infection.

I cannot venture to discuss the bacteriological problems involved, but I am convinced of the great use of vaccines as a supplementary treatment to surgical measures in septic wounds, and am satisfied that the routine employment of a polyvalent vaccine of proteus and streptococcus is of value in inhibiting the tissue-necrosis caused by anaerobic bacilli, which are so commonly associated with these organisms in gunshot-wound infection.

I must thank Colonel R. J. S. Simpson, C.M.G., A.D.M.S., Woolwich, for permission to bring forward this note, and especially my colleague, Mr. Goadby, for the enormous amount of work he has undertaken for me in the examination of my cases and for his ready assistance at all times in the preparation of vaccines for the treatment of the cases.

THE PSYCHOLOGY OF MALINGERING AND FUNCTIONAL NEUROSES IN PEACE AND WAR.

By THOMAS LUMSDEN, M.D. ABERD.

DEPUTY CHIEF MEDICAL EXAMINER, LONDON COUNTY COUNCIL, ETC.

IF individuals complaining of symptoms which are characteristic of hysteria, neurasthenia, or malingering would be so accommodating as to keep within the limits precisely laid down for each of these conditions in our good text-books, the task of the physician dealing with them would be comparatively simple. The fact is, however, that almost invariably the three states mentioned are combined one with another in differing degrees, so that a patient originally hysterical may become neurasthenic, and may also mangle for sympathy or for gain of a more sordid nature. Frequently only two of these disorders are mingled in cases we have to deal with, so it happens that there are in all seven possibilities; a patient may have any of the three conditions in a pure state or any two, or all three at once.

I do not propose here to describe the symptoms and signs of hysteria or neurasthenia in detail, since these can be found in any ordinary text-book of practice of medicine; I shall instead take a few clinical cases as examples and discourse upon them in the light of the experience I have accumulated and the principles which seem to me to emerge therefrom.

Hysteria.

CASE 1.—I was called to see this young woman, and found her lying on a bed, being held down by six people while she was going through the evolutions characteristic of hystero-epilepsy. Her "fit" had already lasted half-an-hour and showed no sign of ceasing. She was waving her arms and legs, wildly jerking her body now up, now down, frequently assuming the opisthotonic posture and resting on her head and heels; at other times she kept banging her head on the pillows. I removed everyone except her mother from the room, laid her on the hard floor instead of the comfortable bed, and suggested that the fit was about to cease and that certain signs about her eyes showed this, adding that if it did not stop within two minutes it would be necessary to throw cold water right over the patient. The "fit" continued in spite of this threat, but having obtained a pail of water, and splashing a little of it on the patient, with the apparent intention of emptying the whole over her if necessary, the patient rapidly recovered. She was put to bed and was quite normal to all appearance next morning.

This was an example of pure hysteria and shows the following characteristics. The cause was emotional and the fit was in the line of an explosion of suppressed and accumulated feelings—a sort of emotional Jacksonian epilepsy. This is very characteristic of hysteria; whether it shows itself as aphonia, paralysis, or as a simple hysterical fit it is in every case an outlet for suppressed emotion, and is associated with a subconscious desire for sympathy or notoriety.

Hysteria is more a lack of will to do right than a will to do wrong. Looking deeper behind that illusive term "will" we find that in the hysterical patient the highest centres cease to control the lower subconscious centres, inhibition gives way, and the abnormal manifestations appear. All my experience of hysteria leads me irresistibly to the conclusion that this disease is nothing but the vicarious expression of unsatisfied desire, usually of a sexual nature. Civilisation and popular morality deny such desires and many other motives, their natural outlet, yet these motives are so powerful that some discharge of all the potential energy they represent must take place, and hysterical symptoms are the result.

All action may be regarded as the modified result of the energy which accumulates in the brain, by the summation of afferent impulses and of the desires (memories of pleasures) which they awake. When there is nothing to prevent the normal and evident action suggested, all is well; the desires are satisfied and the potential energy they represent is dissipated. But when custom, public opinion, conscience, &c., raise objections a struggle ensues; the normal outlet may be prevented, but the potential energy is not used up yet, and accumulates till it compels some expression for itself, and hysterical manifestations result. Who, then, is to blame for the condition—the patient whose desires are clearly beyond her own control,

or the public opinion and laws which deny those desires their normal outlet? I personally blame the unnatural conditions of our so-called civilised life; I pity the individual, while I blame the system and the lack of human charity.

A more profitable line of inquiry is, How are we to prevent or cure such cases? My answer is: In a general way prevention is only to be attained by our resuming or acquiring more natural habits and customs, and this can only come from a more intimate study and knowledge of ourselves and our environment; of Nature and her laws: once these are truly appreciated, they will involuntarily be followed, and evil results of unnatural restrictions (e.g., hysteria) will disappear. Sin after all is merely ignorance. Evil is only folly misunderstood and misnamed. To work out this hypothesis is a wide subject which must be reserved for another occasion.

In any particular case cure is to be sought only in two directions: (1) By arranging that the desires attain a sufficient outlet, e.g., in the case of sexual desires by marriage before the brain has become permanently warped; and, alternatively (2) if this is impossible, then by other forms of occupation the energy which has been finding unnatural expression may be used up through some different channel; hard physical work will prevent lust, and charity may replace a craving for selfish sympathy. Altruism makes in the end for happiness, while egotism leads to misery, worry, and hysteria.

Neurasthenia.

CASE 2.—The patient comes to me complaining that he has lost all his energy, he gets exhausted on the least exertion either mental or bodily, his memory is failing, he has lost all interest in his work and even in his amusements, he suffers from pains in his head and back, he is losing weight, and his sleep has become fitful, uncertain, and unrefreshing, his appetite is poor, he suffers from "indigestion," and he has a sense of depression so deep that he has even contemplated suicide. I find on inquiry that he has been overworking himself for months past; he has also been worried monetarily and at home. He is weak but irritable, and is a pure example of neurasthenia.

Each of us has a banking account in the nerve energy bank, and our state of well-being (in this direction) depends on our balance at this bank. If our expenditure is too great or our income insufficient, our balance inevitably declines or disappears; we may even become entirely bankrupt; we then suffer from neurasthenia. This bank is in our brain cells, and the substance we pay into it is the mother substance of thought and energy—cf., myosinogen in the case of muscle. We make this substance, which I propose to call "ergogen" from our food, if it is sufficient and if our digestion is good; sufficient sleep diminishes our expenditure of it. Work, and especially mental work, and worry use up ergogen and thus diminish our "balance" of it in the brain cells. Cure of neurasthenia is thus to be sought in two directions: (1) By increasing our income of ergogen—i.e., taking sufficient food and digesting it thoroughly; (2) by diminishing our expenditure of this precious substance by sleeping and resting sufficiently, and by avoiding worry as far as may be.

A fact which is sometimes overlooked is that brain cells depleted of ergogen are irritable and hypersensitive, though they are weak for action. I sometimes compare them to a supposititious regiment of old colonels, who would be very irritable and peppery, very prone to wrath, if you trod on their toes, and yet they would be of very little use at digging a trench, or at marching on the toes which seemed so full of energy when trod upon by others.

Another characteristic of neurasthenic patients is their tendency to introspection; hence arise all the various aches and pains from which they suffer and of which they bitterly complain. In many instances they magnify by this means the normal bodily and organic sensations into aches and pains. It is as though they saw their own interiors with the fovea centralis of the mental vision instead of with the retinal periphery of the mind, as the normal man should; or, again, as if they always heard their own internal clock ticking, instead of disregarding its sound as long as it is regular and normal, as we do in the case of a clock ticking regularly in the room we are working in.

Weir Mitchell treatment cures these cases by diminishing work and increasing the ergogenic income by special dieting. Equally effective as a means of cure is residence at a quiet farmhouse, with at first rest, and later a gradually increasing amount of exercise, and good country feeding all the

time. I sometimes tell people to approach as nearly as possible to the type of existence of a turnip, or, if they prefer it, of a lily or a rose.

Malingering.

CASE 3.—A workman in the employment of a public company, which pays half wages to those injured on duty, and who is a member of two clubs and comes under the State insurance scheme as well, has hurt his arm while on duty; he now complains that the shoulder-joint is stiff and that he cannot raise his arm as high as his head. I find on examination now no evidence of past injury or present disease (the alleged accident was ten days ago). On making him place both hands on a chair-back and then step away from it, so that I may examine his back, his head descends readily between his shoulders; I then catch hold of his arm and tell him to stand up, when, of course, he is disappointed to find that he has been tricked into raising his "injured" arm till it is in the same line as his spine, and therefore high above his head, and this although my attempt to raise his arm before had elicited gasps and heartrending wails of pain. As there is a witness present he can no longer deny his fraud. I find on adding up his club money and half-pay under the Workmen's Compensation Act that his income when ill is actually greater than when he is at work. A further temptation in this case was the stupid provision of the Act that a man must be absent for 14 days if he is to be paid compensation right from the date of injury, and so this man was most anxious to remain off work till that period at the least. While dressing himself the man raised his arm quite freely as he put on his shirt.

This was, of course, a case of pure malingering, and there was, as one always finds, a clear motive for feigning disability. The motive was largely a monetary one, but there have been many examples recently of malingering in order to avoid military service. Malingering is an instance of wilful fraud, and is in one sense equivalent to theft, where a monetary gain is the one sought for; but in many of the combined cases, e.g., hysteria plus malingering, the gain looked for may be only notoriety or sympathy (see Case 4).

Combined Cases.

Hysteria and malingering.—Very many cases of hysteria have an element of malingering about them; indeed, hysteria may be looked upon as a sort of subconscious malingering in which the patient herself is deceived as well as, and sometimes even more than, others round her; to this subconscious fraud it is very common to find conscious fraud superadded.

CASE 4.—The patient was brought to me for a wound of the elbow. She was 17 years of age, and had the furtive look so characteristic of this type of hysteria. On examining the wound I found lying on the surface a piece of glass. The wound was a very superficial one, but had a good deal of blood round it, and the dress was also blood-stained. The patient said she had cut her arm by mistake, having put it "through the window" while attempting to open the same. The wound did not look as if it had been caused in this way, and on investigation it was found that the patient had just previously had a quarrel with her governess, and her parents had rather taken the latter's part. Being much annoyed, the patient went up to her own room and almost immediately returned with the wound mentioned; further, it emerged that one of the housemaids had seen from another window her young mistress deliberately break the window with a book. It is evident, therefore, that this was a case of a hysterical girl emotionally upset by a quarrel in which she had got the worst of it, and who deliberately broke the window and then scratched her arm in order to regain the sympathy she had forfeited, and to make those round her sorry that they had been hard upon her. This young lady was addicted to typical fits of hysterical weeping and laughter when emotionally upset.

Hundreds of cases of the combination of malingering and hysteria could be given, but Case 4 is sufficient. It is not surprising that this combination is so common, since the border-line between the conscious and subconscious parts, or rather phases, of our brains is not sharply defined; indeed, the one state passes imperceptibly into the other. "Concentration" passes gradually into reflection and musing, &c., as a river flows into the sea.

A case of hysteria entirely free from malingering is almost a rarity, so frequent and close is the association of the one condition and the other. The aim of the malingering is, however, seldom sordid in these cases, being only for sympathy, or at worst notoriety, as in the case of "blind" or paralysed girls who get their names into the papers every now and then, generally under the heading of "miraculous cures," and so on.

Hysteria and neurasthenia.—The combination of hysteria and neurasthenia is also very common, especially in the

patient's later years; indeed, I think it would be true to say that every uncured case of hysteria will become neurasthenic if the subject lives long enough.

CASE 5.—This patient, 40 years of age, had been typically hysterical in her youth. She never married, though she had had opportunities of doing so, because she did not wish to leave her mother, who would then have had to live quite alone. Two years ago the mother died, and the patient is now a typical hysterical neurasthenic; she has no energy, and she spends most of her time on the sofa, practically her only interest in life being her own complaints, whose name is legion. She is never free from "neuralgic" pains, mostly in the head and spine. She does not really wish to get well. I once nearly cured her by treatment in a nursing home, but finding herself putting on flesh and otherwise making good progress she insisted on coming out of the home and giving up the treatment. Another practitioner now listens to her woes and ministers thereunto.

There is, of course, a stage in these cases where it would be difficult to say whether the disease was more hysterical or neurasthenic; and, indeed, it does not matter much, for the treatment is the important thing, not the name. Wherever neurasthenic symptoms are present it will be well to treat, and if possible remove, them; but it may happen, as in the case just cited, that the hysterical part of the patient will resent the disappearance of any of her beloved symptoms, in which case, if, as is likely, the hysteria is a deeply-ingrained and old-standing disease, cure is very difficult or impossible. We may try to help the sufferer to regain some of the *joie de vivre* and to wish again to get well, and if we succeed in doing this by means of suggestion and the strength of our personality all may go well; but we have to deal with the ever-present harmful autosuggestion of the patient, and results are apt to be disappointing. Marriage, even at a comparatively advanced age, gives perhaps the best hope of cure if only the right man can be found; but the "right man" is usually not forthcoming, and I for one do not blame him.

"*Traumatic neurasthenia*" and "*shell shock*."—The true neurasthenic does not mangle; he is as much deceived as deceiving. It is true that he exaggerates sensations, making in this way mountains out of mole-hills, but this process is quite involuntary, and there is nothing to be gained by him; he really suffers very much as the result of his hypersensitiveness. Many doctors may disagree with this dictum, but I think if they do it will be because they call certain cases neurasthenic which I do not regard as such. For instance, there is a condition following after accidents which is often called "*traumatic neurasthenia*." A workman, it may be, is injured in a tramcar accident; he suffers considerably from shock at the time, and complains thereafter of pains in the head, giddiness, weakness in the back, palpitation, and so on. Such patients frequently mangle, but are they initially and essentially neurasthenic? I think not. I look upon them as late results of an emotional shock, and hold that they are in fact hysterical or mixtures of hysteria and malingering. Only when they have become inveterate, a neurasthenic element may appear, as it does in every hysterical case which lasts long enough; the case then becomes an example of the combination of all the three disorders mentioned above—hysteria, neurasthenia, and malingering. After a shock, for instance being blown up on a ship which is torpedoed, a sailor or passenger may lose his nerve so much that he shudders at the sight or even at the thought of a ship or the sea. This state (in so far as it is unreasonable) I look upon as clearly hysterical, a result of disordered emotions; it is true that it may induce neurasthenia if the man's livelihood entails voyaging, as he will worry for the loss of his occupation and pay, but the condition is not essentially neurasthenic.

Very rarely it may happen that a man who is already neurasthenic may have that condition aggravated or precipitated by an accident, but the accident is here only the last straw, and is not the real cause of the neurasthenia, and such are not the cases which are connoted by the misbegotten term "*traumatic neurasthenia*." Most of the cases of so-called "*shell shock*" are of this nature and very clearly show the stigmata of hysteria; they suffer from such symptoms as stammering, twitching, choreic or convulsive movements, anæsthesias and paræsthesias, all of which are hysteroid manifestations and not neurasthenic, as also are the loss of voice, sight, and sense of identity which are now and then results of "*shell shock*." The strain and worry of war do produce a number of cases of neurasthenia, but

these are just the same as neurasthenia produced by similar causes (overwork and worry) in peace time, and are not the cases which are designated and advertised under the misnomers "*traumatic neurasthenia*" and "*shell shock*," terms whose vulgarity will always be associated in my mind with such horrible expressions as "*Doing your bit*" and "*We shall win through*."

As in all other cases of neurasthenia, these instances just mentioned as being due to the stress and worry of war conditions suffer from a lack of ergogen, and all that is required to cure them is peace, rest, and good country feeding, while the hysterical "*shell shock*" cases require and will be cured by firmer handling on "suggestive" principles. The cases into which malingering (as well as hysteria) enter form a third class to be dealt with similarly, whether they arise as the result of war, of accidents in peaceful times, or of a desire for sympathy or notoriety, as mentioned above.

Conclusions.

Hysteria is to be regarded as a disorder of the sub-conscious phase of the personality, in which suppressed desires and emotions manifest themselves vicariously by symptoms referable to any or all of the cerebral activities, motor, sensory, vaso-motor, or sympathetic. In hysteria the highest conscious centres and cells lose their control over the lower cerebral centres, which then act under the direction of the sub-conscious and emotional areas. The motives being denied outlet in their normal direct course find expression in some perverted and abnormal direction.

Neurasthenia is the state which results when the brain cells are deficient in "ergogen." The patient is bankrupt as far as energy goes, yet hypersensitive of afferent impulses reaching the brain. Rest and nourishment restore the balance of ergogen and so cure the condition. In this disorder a vicious cycle of weakness and worry is common; dyspepsia and depression, &c., may be similarly associated.

Malingering connotes the fraudulent feigning of symptoms or signs of disease selfishly for gain, and is a disease of the highest conscious cerebral centres in the frontal lobes.

As regards these conditions in relation to the war, pensions, and so forth, much harm has resulted from confusion between the three classes of cases referred to above—viz., (1) cases of pure neurasthenia due to overwork or worry; (2) hysteria following shock, i.e. the so-called "*shell shock*"; (3) hysteria combined with malingering, the gain sought for being either exemption from military service or a pension. Besides these there are, of course, cases of pure malingering.

I append in tabular form a résumé of the main distinctions between the conditions here dealt with.

Table showing the Main Distinctions between the Conditions dealt with.

| | Hysteria. | Neurasthenia. | Malingering. | Shock. |
|------------|--|--|---|--|
| Cause. | Heredity; emotional upset; female sex; repressed (generally sexual) desires. | Heredity; worry; overwork; debilitating diseases; masturbation. | Dislike of work; desire for money, ease or sympathy not earned. | Accident; injury, physical, mental; operation; hæmorrhage. |
| Onset. | Sudden, varies. | Gradual, even. | Varies. | Sudden or gradual. |
| Symptoms. | Emotional; mercurial temperament; quick active mind, may be brilliant; protean symptoms involuntary, or may mangle, too; globus, spasms, fits, faints, &c.; "sub-conscious malingering." | Weak for action, but hypersensitive; memory weak; mind and body easily tired; introspective; dyspeptic; depressed and irritable. | Any which are easily feigned; pains in back; giddiness; lost senses, e.g., sight, &c., corresponding with the gain sought for; voluntary and conscious. | Collapse; cold sweat; dilated pupils; weak pulse of low tension; pallor. |
| Cure. | Marriage; full and pleasing occupation; suggestion. | Sleep, rest, and food build up ergogen; exercise later. | Detection, or if it ceases to pay well. | Stimulants, fluids, alkalies, rest, food. |
| Pathology. | Motives get beyond conscious control; "auto-suggestion"; "buried complex." | Brain cells run down; bankrupt of ergogen. | Conscious and fraudulent; a moral cell disease. | Falling blood pressure; brain cells ill supplied with blood. |

South Eaton-place, W.

THE ANGLE OF THE DROPPING PIPETTE AND ACCURACY IN AGGLUTINATION TECHNIQUE.

By R. P. GARROW, M.D. ABERD., D.P.H.,
CAPTAIN, R.A.M.C.

IN an interesting article on the Serum Reactions of 300 Unselected Cases of "Enteric" in THE LANCET of August 5th, 1916, Professor Ernest Glynn and Dr. E. Cronin Lowe state, *appropos* of accuracy of technique: "It is *probably* advisable (the italics are mine) to hold the dropping pipette at the same angle when distributing the drops." If any doubt exists in their minds on this point it may be readily dispelled by the following simple experiment, which shows it is necessary that, in order to secure accuracy in dilution, the dropping pipette should always be held in a vertical position throughout the entire process of distributing the drops.

Experiment.—Part 1.—Deliver at a uniform speed into a wet test-tube 100 drops of normal saline solution from the dropping pipette contents of the and again deliver drop by drop at test-tube, this an angle of 80° this process at 20°, 10°, and in This can readily test-tube, in the cardboard on

are marked by lines. The dropping pipette is held against these lines while its contents are being delivered into the test-tube. (See diagram.)

Part 2.—Now fill the dropping pipette with normal saline and drop 100 drops at a uniform pace into the test-tube, holding the pipette vertically. Draw up this saline into the pipette again and discharge it a second time with the pipette still held vertically. Repeat ten times.

Result of experiment.—Part 1.—The number of drops obtained for the various angles from the vertical to the horizontal were:—

| | | | | | | | | | | |
|------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|----|
| Angle... | 90° | 80° | 70° | 60° | 50° | 40° | 30° | 20° | 10° | 0° |
| No. of drops ... | 100 | 100 | 95 | 88 | 82 | 75 | 66 | 62 | 54 | 48 |

Part 2.—The number of drops obtained from the same volume of normal saline discharged at a uniform rate, ten times, the pipette held vertically, were:—

| | | | | | | | | | | |
|-----|-----|----|----|----|----|----|----|----|----|----|
| 100 | 100 | 99 | 99 | 99 | 99 | 98 | 98 | 98 | 98 | 98 |
|-----|-----|----|----|----|----|----|----|----|----|----|

The loss of two drops is, no doubt, due to evaporation.

Conclusions.—1. The number of drops, and therefore the size of each drop, which a dropping pipette will deliver from a given quantity of a liquid varies considerably with the angle at which the pipette is held.

2. For an equal variation of angle—e.g., 10°—the dilution error tends to be greater the further the angle is from the vertical.

3. The only correct position in which to hold a dropping pipette is the *vertical position*. It is the easiest to adopt and maintain accurately, and it is the least liable to error from slight alteration of angle.

4. The drop method, when used intelligently, is an extremely accurate method of making a series of dilutions for the estimation of the relative agglutinating titre of blood serum.

Medical Societies.

MEDICAL SOCIETY OF LONDON.

Epidemic Nephritis.

A MEETING of this society was held on Nov. 13th, Lieutenant-Colonel D'ARCY POWER, the President, being in the chair.

Captain LANGDON BROWN, R.A.M.C., opening a discussion on Epidemic Nephritis, said that acute nephritis was rare in men of military age. In wars it was not common, apart from the American Civil War, in which 14,000 examples of nephritis occurred, but this number included cases both of acute and chronic nephritis. In the central army the number of cases rapidly increased, the incidence rising for 12 months and reaching as high as 1.5 per 1000. This was not repeated in subsequent years. In that war the military conditions were somewhat similar to those of the present war, a rapid advance and retreat being followed by a period of prolonged trench warfare. The units were involved in the same irregular and patchy manner. In our own army, up to the end of June, 1915, there were 1062 cases. Few occurred before February of that year. They increased until 1916, when there was a steady fall. The Belgian Army had been unaffected and the French Army little until July, 1915. In the Mediterranean zone cases did not occur prior to the movement of French troops to that area. A similar outbreak appeared among the German and Austrian troops. The cases on which the paper was based fell into groups. One of 58 studied at St. Bartholomew's Hospital, the other of 108 at the 1st London General Hospital. Nine were from the Mediterranean, the remainder from France. Few officers were included, numbering only 5 of the whole series and two others in addition. The cases were haphazard in their distribution. Only one patient had been in France for less than one month. The numbers increased for each month's stay in France, but fell again after the seven months' period was reached. Exposure could not be held to be of etiological importance, for there were few cases during the worst weather and the number increased after the spring when the violent fluctuations of temperature were passed. In the South African War there were practically no cases of nephritis, although the range of temperature was enormous. The same was true of the Suvla Bay operations and of the Russo-Japanese War. In 22 only of 186 cases in which the point had been elucidated was there a history of the patient having been wet; in the remainder there was no story of exposure. Cold, however, accentuated chronic nephritis. There was no evidence that the affection was dependent upon the water-supply as had been suggested. The solder and lead which might contaminate tinned foods had been blamed by some, but this was not a likely explanation or the condition would have been present in South Africa and Suvla Bay, where tinned foods were much employed. The urine of nephritis of metallic origin was, moreover, of a different character. By others excess of protein and a deficiency of fresh vegetables in the diet were held responsible, but this would not explain the increase in the French Army in July, 1915, nor was

¹ A chart showing the incidence of nephritis among the Northern Armies during the first part of the American Civil War appeared in THE LANCET of Feb. 19th, p. 392.

there any evidence of a co-existent intestinal toxæmia. Wounded soldiers were not especially liable to nephritis. It had been suggested that the nephritis was a complication of an epidemic of a suppressed form of scarlet fever, and the comparative freedom of the Indian troops, who are immune to that infection, was cited in evidence, as well as the occurrence of sore-throat at the beginning of the attack. A history of early sore-throat was obtained in 27 per cent. of his cases, but he regarded it as secondary to the cough. There were many points of similarity between scarlatinal nephritis and this form, but such a view would mean that there had been 10,000 cases of scarlet fever, all suppressed, and all free from desquamation, which seemed impossible. A previous history of nephritis was obtained in 13 only, so it could hardly be due to recrudescence of former nephritis. Nor was antityphoid inoculation the cause, for nephritis had not occurred in a similar manner among the troops at home or in South Africa. That the condition was due to a specific infection was suggested by the fever at the onset and preceding relapses, the spread to the French troops four months after its occurrence among the English and to the Mediterranean area when troops were transferred there from France. Its patchy distribution also resembled that of cerebro-spinal fever. The results of post-mortem examinations pointed to an involvement of the glomeruli and tubules, as in an infective nephritis. Examination of the urine, however, had afforded little support to this view, for of 21 examined bacteriologically 18 were sterile. Blood cultures were also sterile. Various organisms had been isolated from the throats of affected patients, but not more frequently or in greater numbers than among controls, and antibodies to these organisms were not found in excess in the blood. In two cases, however, Dr. Mackenzie Wallis had been able to reproduce albuminuria in rabbits by inoculating them with the urine of affected persons, and this after an incubation period of eight days, which corresponded approximately with the incubation period as estimated clinically. His investigations suggested that the infective agent was ultra-microscopic and filter-passing. A positive Wassermann reaction was obtained in 18 out of 56 cases examined; this might mean a corresponding incidence of syphilis, or, on the other hand, be due to another animal infection such as that by a filter-passing organism [was supposed to be. Considering next the symptoms of the disease, he said that the incubation period was between 6 and 15 days. Premonitory symptoms, according to Captain Abercrombie, were met with in about half the cases, and were bronchitic, febrile, or abdominal (pain and vomiting). (Edema was usually the first symptom noticed, and was present in 97 per cent. of the cases, but generally lasted only a few days and was not often considerable. Early dyspnoea was noticed in 76 per cent., starting usually at the same time as the oedema, but ceasing sooner. It would appear from estimations of the alveolar air that the dyspnoea was not always associated with acidosis, uræmic or otherwise, and was possibly explained by a similar effusion into the lungs. He had not observed the wide fluctuations of the blood pressure described by Abercrombie. The commonest systolic pressure was 140 mm., and there were but few patients with a really high pressure, and these were men who had been painters or plumbers in civil life. The difference between the systolic and diastolic pressures was very considerable, being about 10 c. mm. Hg. These findings would account for the fact that cardiac hypertrophy and arterial changes were little evident. The urine was often much increased in amount, even in the acute cases. Red blood cells were seen in it in 102 of the 166 cases and white corpuscles in 79. A flocculent reddish-brown precipitate containing blood elements was commonly met with. Casts were found in the majority. There were blood casts in 2, epithelial in 37, fatty in 7, granular in 73, hyaline in 58. Retinal changes occurred in 18 per cent. and convulsions in 4 per cent., but these generally yielded quickly to venesection. As occasional symptoms were herpes and parotitis, suggesting an infective origin. Milkiness of the blood serum was not found in any of the specimens withdrawn for the Wassermann reaction except in one fatal case. Two cases only out of the 166 were fatal; in the majority the patient felt well when the oedema had subsided. The albuminuria was intermittent, and often relapsed, ceasing after a period of from 14 weeks to 5 or 6 months. Recovery might be complete after a long period of albuminuria. He considered

that all soldiers who had suffered from nephritis should be regarded as unfit for foreign service, and if the albuminuria persisted for more than four months should be discharged. The diastase output must have returned to normal before a cure could be said to have been established. As treatment he recommended a low nitrogenous diet during the acute stages, but one containing considerable variety. The diet suggested contained 43 grm. of protein, 285 grm. of carbohydrate, and 50 grm. of fat, with a total calorie value of 1815. When the acute stage was over this might be replaced by an ordinary nitrogenous diet, including mutton or fish, and might contain as much as 95 grm. of protein, the total calorie value being 2690. His experience with theocine had been unsatisfactory, the drug appearing to act as a renal irritant as well as a diuretic and being unsuitable in acute cases. The same was true of diuretin. It was impracticable to flush out the kidneys in acute nephritis, but there was a risk in diminishing the intake too much. Hot-air baths had definite limitations; they were only useful if followed by diuresis. For hæmaturia he found no drug of certain value. With dry cupping his experience had been unfortunate. Venesection was valuable for cases not doing well and most efficacious for convulsions.

Lieutenant W. H. DUNN, R.A.M.C., recounted his clinical experience of nephritis in France in the casualty clearing station zone. No composite picture of the symptoms could be drawn, but a fairly clear group could be selected as characteristic. The patients had the appearance of health, showing little anæmia or loss of flesh. Dyspnoea was very common, but not urgent. The urine was usually considerable in amount and seldom diminished. The amount of albumin was usually 2-4 parts per 1000, but in some cases was 8 parts per 1000, and higher figures had been met with. In spite of this the urine was clear and was not smoky. The casts were commonly hyaline and epithelial; blood casts were uncommon. Rapid improvement was the rule. There was usually no fever. In some cases blood was passed in considerable amount; then fever was often associated. He was at a loss to assign any general cause. Against an infective process, like scarlet fever, was the fact that although the troops were in close contact with civilians the latter were unaffected. There was nothing to support the view that the ground was infective in particular areas. He had studied the pathological anatomy in 24 cases in all, of which 17 acute cases and 2 subacute cases were of the kind of nephritis under discussion. Little could be detected by the naked eye, except that on the cut surface of the cortex the glomeruli projected slightly as grey translucent nodules, not as red nodules, such as were seen in ordinary acute nephritis. Microscopically, catarrhal changes in the tubules were indicated chiefly by degeneration of cells; fatty changes were seen in some cells. Tubular hæmorrhages occasionally appeared. The main changes were found in the glomeruli. They were enlarged, and often pouted into the tubules, their cell content being increased. Desquamation of the covering epithelium was sometimes present. The vascularity was diminished. The capillaries were dilated, and contained abnormal nucleated cells. There was little evidence of reaction or degeneration. Proliferation of the epithelium was met with. In two cases total infarction of the tufts was found, due to occlusion of the afferent arterioles. These changes corresponded closely with the book descriptions of glomerular nephritis, and were therefore not new. Special examination of the organs had failed to give any evidence of a bacterial cause. The lungs in one case were found to be acutely emphysematous and oedematous and to contain diffuse patchy hæmorrhages. The spleen also was the site of numerous small hæmorrhages and was slightly enlarged. Similar hæmorrhages were found in the brain. Detailed examination of the lungs showed a peculiar lesion of the walls of the infundibula and ends of the bronchioles. These were prominent and covered by dense fibrin, and had the appearance of having been cauterised. The changes found resembled those following the inhalation of Cl_2 or other irritant gases. The large bronchi showed a similar condition. In two other cases like changes were found, and in four others lesions showing a comparable but not identical change. In six out of the seven there was evidence of thrombosis of the capillaries in relation to the infundibular damage. Hæmorrhages occurred in the spleen and brain in two cases and were apparently embolic in origin. It

seemed that in many there was a process of multiple embolism in being, and this suggested that the kidney lesion was similarly caused, but no thrombi had been found in the glomeruli. In shell-gas poisoning the lung condition was very similar, and thrombosis of the pulmonary capillaries and cerebral hæmorrhages of embolic origin also occurred. In one case the kidney contained thrombi in the glomerular capillaries; in others there were no thrombi there, but proliferation of the endothelium. It was possible that thrombi had previously been present. Although it was not suggested that the nature of the irritant inhaled was drift gas or shell gas, it seemed clear that the origin of this form of nephritis was to be found in capillary embolism, and it might be in emboli derived from the lung lesion, which was of the kind recognised as due to an inhaled irritant.

Mr. W. H. JESSOP said that of 75 cases he had found that 71 per cent. had retinodema with the occurrence of plaques and sometimes of detachment of the retina. There were few hæmorrhages. 57 per cent. of the patients were between 20 and 30 years old. The vessels were unaffected and the blood pressure was normal. All these changes could be watched from time to time and be seen to disappear. He could not but conclude that they were due to toxæmia, as also was the œdema elsewhere.

Mr. J. E. ADLER said that he had met with blood casts on several occasions. He regarded the diastase test as of the utmost value. In acute nephritis there was generally a low diastase reading. In 800 readings it varied from nil to 40. In the majority of cases a diastase value consistently low was evidence of low renal efficiency. Of 69 cases with a low diastase value, 31 showed blood in the urine and 38 no blood; occasionally blood was found with a high diastase reading. The pthalein test was the most valuable. To perform this 6.6 mgm. of pthalein was injected intramuscularly and the bladder emptied 1 hour and 10 minutes later, and every hour up to 3 or 4 hours. The test depended upon the amount excreted at the different hours. The amount excreted during the first hour should equal the total of the amounts passed at the end of the second and third hours. It agreed with the diastase readings in showing that the permeability of the renal cells was markedly decreased in nephritis, and it also indicated the advent of uræmia. The diastase readings and the pthalein test results were generally in agreement, but there were instances when the test was more reliable than the diastase values. The disadvantages of the diastase test were that a 24 hours' specimen was necessary, the readings were variable, much time and special apparatus were required, and the starch had to be made fresh every day. Its use necessitated laboratory work. He thought that both tests should be carried out in every case to enable a decision to be arrived at as to what should be done with the patients.

ROYAL SOCIETY OF MEDICINE.

SECTION OF DERMATOLOGY.

Exhibition of Cases.

A MEETING of this section was held on Oct. 19th, Dr. J. H. STOWERS, the President, being in the chair.

The following cases were shown.

Surgeon D. LOUGHLIN, R.N. (for Dr. H. BATTY SHAW): Case of Leukæmia Cutis. The patient was a man aged 37. Purple-coloured patches first appeared on his body eight months ago. Three months later an ulcer developed over the sacrum, and within another month lumps, which have gradually been getting bigger since, appeared in the skin of the trunk, limbs, and face. The patient was ill, febrile (temperature 101°-102° F.), and had the leonine facies typical of the condition. The lymphatic glands were not enlarged, and neither the liver nor the spleen could be felt. The blood count showed a diminution of red cells, some of which exhibited vacuolation and poikilocytosis; also macrocytes and microcytes were seen. The white cells were absolutely decreased, but there was a relative increase of lymphocytes. The histological specimen showed the typical infiltration of the tissues with lymphocytes.—Dr. F. PARKES WEBER recorded a somewhat similar case, which had been published under the name of Granuloma Fungoides.—The PRESIDENT referred to another case similar to the one shown exhibited by Dr. Lidiard at the first meeting of the Clinical Section.

Dr. H. G. ADAMSON showed, amongst others, a case of Schamberg's Disease. The patient was a man who had a chronic punctate inflammatory condition of the skin on one shin. When the lesions disappeared they left pigmented marks.

Dr. A. WHITFIELD: Cases of Pruritic Dermatitis caused by infection of mange from a kitten. The lesions differed from those of ordinary scabies, as they were small papules surrounded by an oval zone of erythema, and in some instances surmounted by a minute pin-head-sized vesicle looking not unlike a varicella papule. The lesions were generalised, but the fingers and wrists were free. In the kitten the acarid and a run, including eggs and faeces, were found in some scales removed from the skin behind the ears.

Dr. J. H. SEQUEIRA showed, amongst others, a case of Erythremia in a man aged 28.

Dr. S. E. DORE showed a case of Localised Sweating of the Face and Hydrocystoma.

Dr. PARKES WEBER: Case of so-called Multiple Pigment Sarcoma of Kaposi. The patient was a Russian Pole, 26 years of age, who came to England when he was 1 year old. The disease began two years ago on the left hand. Microscopically the lesions were typical—i.e., the most prominent feature was the large quantity of thin-walled blood-vessels surrounded by a number of fibroblasts.

The PRESIDENT exhibited a case of Circumscribed Scleroderma (Morphea) in a girl, aged 7 years, of extremely nervous disposition. The child of healthy parents, she was stated to have developed the disorder a few weeks after being suddenly awakened at midnight by a bomb explosion one year ago.

An abstract of a paper on Acnitis in an Egyptian soldier was communicated by Dr. A. G. CHALMERS and Dr. J. MARTYN, and illustrations were exhibited.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—The first meeting of the session was held at the Leeds General Infirmary on Oct. 27th, Mr. W. R. Bates, the President, being in the chair.—The President gave some notes of cases that he had had the opportunity of observing over a long period. The cases described were of considerable clinical variety, and showed how uncertain was the element of prognosis.—Professor J. B. Hellier read a paper on the Treatment of Placenta Prævia, in which he discussed the place of Cæsarean section in dealing with this condition. He said that when there had been one well-marked hæmorrhage modern opinion was strongly in favour of terminating the pregnancy without delay. Given a patient who was not in labour and who had an uninfected genital canal, Cæsarean section by a man accustomed to abdominal surgery might be strongly recommended. He quoted three cases in point. In one a woman, who had a severe attack of flooding, had been treated expectantly, and a second attack of flooding had proved fatal before she could be delivered by version. In two other cases, after the first hæmorrhage he had performed Cæsarean section and had saved both mothers and children. He recommended that such cases should be transferred to nursing home or hospital after the first hæmorrhage for treatment by hysterotomy. He did not say that all cases of placenta prævia should be treated by Cæsarean section, and many would still be treated by version, but he strongly insisted on the importance of waiting after version had been performed till the uterus expelled the child by natural efforts.—The President showed three original photographs taken by Captain Shearer, R.A.M.C., by his method of depicting organs *in situ* in the living body: (1) Brain and medulla, (2) brain showing hæmorrhage into arachnoid and cerebral abscess, (3) normal intestines.—Mr. G. O. Hayes showed some cases of inoperable malignant disease which had been treated with diathermy with considerable benefit.—Mr. J. F. Dobson and Dr. J. Stewart showed a patient for whom an ileocolostomy was performed three years ago for advanced rheumatoid arthritis.—Specimens were shown by Mr. L. R. Braithwaite and Mr. A. Gough, and microscopic slides by Dr. C. W. Vining, Dr. M. J. Stewart, and Dr. W. H. M. Telling.

DORSET COUNTY COUNCIL AND VENEREAL DISEASE.

—At the last quarterly meeting of the Dorset county council it was decided to establish treatment centres for venereal disease in six towns, and Mr. W. B. Cosens, with Dr. T. Howard, both of whom are magistrates, will assist the council in the scheme.

Reviews and Notices of Books.

Traitement des Fractures: Fractures Articulaires.

Par R. LERICHE, Professeur Agrégé à la Faculté de Médecine de Lyons. Avec 97 figures dans le texte. Paris: Masson et Cie. 1916. Pp. 190.

IT is a curious fact that before the war more German text-books in medicine and the allied sciences were read in this country than books written in French, though it is certain that many more medical men in the British Isles can read French than German. It is difficult to explain this fact. It is not through any lack of French medical literature, for the French press is prolific in medical works. Perhaps the explanation is to be found in the idea that the profession in Germany was more thorough in its methods than in any other country. Be this as it may, the advent of the war has directed the attention of British medical men to the medical literature written in the French language; and the interest felt in French works on medicine and surgery is increased by the fact that the war has given rise to no small number of books on matters directly connected with the war. Among these new books are some composing a series of war-books of which we have a specimen before us, written by a surgeon well versed in the matter which he discusses. He has spent no space on mere theoretical discussions, but has gone straight to the point, and has described his own methods of practice based on his own experience, and thus we have a much more valuable and interesting work than if we had merely a résumé of current opinions.

Professor Leriche deals with fractures involving joints under two sections—the first comprising the general principles and the second describing the treatment of fractures involving special joints. In connexion with the recent discussion in this country on the relative merits of a number of antiseptics in the treatment of wounds received in war, it is of interest to note that Professor Leriche does not approve of the use of any antiseptic whatever, but he puts the greatest stress on laying the wound completely open, even to its uttermost recesses, and this, in his opinion, is the most efficacious method of overcoming the microbic infection of wounds. He also values greatly the exposure of wounds to the sunshine, for he has found that the sun has a very definite action on the healing of wounds and that also it preserves the tonicity of the muscles, so that when the time comes for them to act again they are in the best condition to resume their work. Unfortunately for the use of this treatment, sunshine is not so available as might be desired.

In the section dealing with the individual forms of fractures into joints we need say little more than that Professor Leriche has in the case of each joint described the anatomical types of the fracture involving it, the immediate treatment, the indications necessary for a good functional result, and the post-operative treatment. The book contains a large number of excellent illustrations, many of which are reproductions of skiagrams. It cannot fail to prove of great value to those who have to deal with the almost innumerable cases of fractures into joints encountered in the present war.

Food and the Principles of Dietetics.

By ROBERT HUTCHISON, M.D. Edin., F.R.C.P. Lond. With plates and diagrams. Fourth edition. London: Edward Arnold. 1916. Pp. 617. Price 16s. net.

THE real appreciation of this book is seen in the issue of a fourth edition since it was published in 1900. With a wide public it has been accepted as an authoritative work on general dietetics. It is eminently practical in character, and one of its especial features is the discussion of well-known foods and beverages, proprietary and otherwise. In many instances the author has supplied in regard to these his own analytical data, while he acknowledges much work on the analyses of foods and similar subjects which has been reported from time to time from THE LANCET Laboratory. The significance of chemical results receives adequate treatment; the author states that it is not entirely chemical composition that decides on actual assimilation and appropriation of the elements of food for the body's

needs, while he points out that we often pay a fabulous price for the mere æsthetic qualities of food. He has added in the new edition a chapter on the vitamins, the presence of which in certain foods may, he admits, have to modify our views as to their dietetic merits. This subject is necessarily a difficult one to discuss in all its aspects at the present moment, and in some places the teaching may appear to have fallen behind, and in a few cases some of the proprietary preparations dealt with are no longer extant.

The book continues to be one of the most useful sources of reference on food and dietetics, and the discussion of principles is thoroughly sound. We are glad to note that some errors in the index of the previous edition have been rectified.

New Inventions.

AN IMPROVED GAG.

THE accompanying illustrations represent a gag (Fig. 1) which I have found invaluable in treating the varying degrees of trismus so commonly met with in neglected jaw injuries and gunshot wounds of the face, with consequent cicatrisation. The gag in the closed position (Fig. 2) is 5/16 in. high; as the majority of patients needing treatment can open their mouths to this extent in the incisor region the insertion of it presents no difficulty, and it is surprising how quickly full range of mandibular movement is acquired. I have found this gag absolutely indispensable in inserting the open-bite Gunning splint, the particular type of splint which I have employed with marked success in treating the severer cases of jaw injuries. Another advantage of this gag is that it can be easily manipulated by the patient and can be retained for two or more hours at a time, the range of movement being gradually increased by an occasional turn of the key.

FIG. 1.

FIG. 2.

AN IMPROVED ARTIFICIAL LEG.

WE have had exhibited to us an improved artificial leg which is made of leather, is therefore very light and has joints which work smoothly. Unlike the wooden bucket, the leather bucket, which is used in this instrument, can be easily made to fit the stump by simple lacing and is always under the control of the man who wears it and who, naturally, knows best what is most comfortable. In the "Ipswich leg" the upper bucket has a natural knee formation and works closely inside the top of the lower bucket, while the movement of the foot approximates very fairly to that in the natural limb. The action of the ankle-joint makes the mounting of stairs and curbs easy, and it is stated that even with amputation above the knee a cycle can be ridden with comfort. The leg is attached to the body by a special brace passing over both shoulders and equally dividing the weight. The weight of the instrument is 5½ to 7½ lb., and most of the repairs that are likely to be required can be executed by any saddler or cobbler. Mr. J. F. C. Hossack, F.R.C.S. Edin., writes that he has a favourable experience with this artificial leg.

The makers are Messrs. Griss and Smith, of 52 and 54, Fore-street, St. Clement's, Ipswich.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 18, 1916.

The Problem of the Disabled Soldier.

THE problem of the disabled soldier remains to a great extent undealt with, although we are aware that it is receiving the anxious attention of some of our best thinkers and organisers. In the debate in the House of Commons on Tuesday night, upon the introduction by Mr. ARTHUR HENDERSON of the Bill to establish a new Pensions Board, the magnitude of the difficulty was seen to be apparent to Members, and it must be earnestly hoped that no further delays in action will take place. Seven weeks ago we noticed a Memorandum dealing with the matter from the Committee of Reference of the English Royal Colleges; this stated that the medical aspects of the question were so important as to render advisable an immediate inquiry into the subject by experts, both civil and military. The Committee of Reference has worked in association with the Central Medical War Committee, and the Central Medical War Committee concluded some time ago that the matter was becoming urgent because the difficulties of dealing with disabled soldiers, bad enough at the moment, must grow more serious with the rapid and even daily increase of their numbers.

There are already at the lowest estimate 50,000 disabled soldiers discharged from the military hospitals as unfitted for further service, many of whom might have been enormously benefited by the continuance of such medical, surgical, and special attention as is received while remaining in the Army. The economical view under which they are now being discharged can only be justified if all that is possible is done for them, so that removal from the Army does not imply the reduction of them to civilian inutility. They would, of course, have been retained in the Army had it been considered possible to refit them for active service, but this event appearing to be out of the question, they were discharged. A certain proportion of them must in all circumstances prove unfit to conduct any business in civil life or to become wage-earners or independent citizens; but this proportion can be substantially diminished by the provision of treatment directed to their individual cases, particularly if this is made available for some considerable period. True national economy, just as much as special gratitude or common humanity, indicates that some such course should be pursued, and pursued quickly. A recent statement made by Mr. J. M. HOGGE, M.P., while emphasising the necessity which all recognise of making a quick start in the work, suggested that the Army should keep the men who

were injured or disabled until such time as they were fit to be discharged, one of his principal justifications for this course being the fact that the military hospitals have already absorbed so much of the medical skill of the country. The Committee of Reference of the English Royal Colleges have also pointed out that a large proportion of the specialists in the medical profession were holding commissions, so that while the disabled soldiers remained in a military hospital, depôt, or camp their condition could be supervised by those best qualified to secure satisfactory results, whereas on discharge their treatment was complicated by the absence from civilian duty of those whose advice would be naturally sought. In these circumstances, the great majority of the men being discharged into civil life, the National Health Insurance Commission becomes gravely concerned with the problem of the disabled soldier. When an insured person enlists he automatically comes off his panel, but on discharge from the Army he returns to the panel, and in the majority of cases will be restored to his former doctor's list. Abnormal work is thus thrown upon the panel practitioner, and there is as yet no systematic provision of consultants or specialists who can relieve him of any part of his responsibility or undertake duties which are without his province. These various aspects of the case are now under the consideration of the Secretary of State for War, who is in possession of the views of the Central Medical War Committee and of the War Pensions Statutory Committee on the subject, as well as of the valuable Memorandum of the Committee of Reference of the Royal Colleges. It is earnestly to be hoped that some general and generous plan of discharging the duty of the nation towards the disabled in the war will be set in motion.

The new Pensions Board, whose institution was made public in Parliament this week, has for its task the reconstruction of the administrative machinery for war pensions, and comes, therefore, into close contact with the problem of the disabled soldier. For the pension of the disabled soldier, however promptly handed out, cannot be expected to pay for a long course of special surgical or medical treatment. The defined object of the new Board is to perfect a pension scheme, and the War Pensions Statutory Committee will retain power to make provision for the care of disabled soldiers in respect of their health, after-care, training, and employment. Much of the admirable work which has been carried on by the voluntary committees will therefore be continued. But the medical profession would like to know with some approach to certainty what is the intended procedure. The terms of panel practice were not devised to cover the cases of disabled soldiers; yet the best that can be done for these brave men must be done. If their care falls upon the panel practitioner the best adjuncts to treatment will have to be found, whether we mean here the service of specialists, the provision of institutions, or the discipline which authority gives and under which systematic therapeutics thrive. There must be some men discharged into civil life, but from now on, it seems to us, a different policy should be pursued, and the majority of our disabled soldiers

should be retained with the Army until they are in great measure fit to conduct the battle of civil life. This is the strong feeling of an influential section of the public. Military administration naturally recognises the difficulties of this course, and we should be blind not to do so also. But in Sir ALFRED KEOGH we possess an extraordinarily sympathetic as well as able Director of the Army Medical Service, so that we can feel assured that the cause of the disabled soldier will be treated as a matter of the gravest national importance. Prompt action before the present situation becomes hopelessly aggravated ought to follow upon the deliberation of well-informed persons, commonly inspired with a desire to do their best to restore our disabled men to the highest possible grade of health and earning power.

Pain and Muscular Action.

THE problem of the nature and meaning of pain is as old as the hills. Words expressing pain are found in all languages, and in languages having a common origin the word for pain is etymologically the same. No satisfactory definition of pain has ever been given: the metaphysical interpretations of other days have now only a historical interest, while more modern views are not always free of the implication that they are definitions which do not define. In fact, a body of thoughtful opinion now supports the contention that there is no such thing as a pain-sensation—i.e., that pains (and pleasures, too, for that matter) are not sensations on the same level as, say, sensations of touch. It is held that pain is an affective element accompanying sensation, and depending on its quality, its intensity, and its duration, for the particular effect which it produces in consciousness. The pain of a cut or burn, for instance, it is said, can be analysed into a tactile or a temperature sensation on the one hand, and a feeling of displeasure on the other. Were pain a sensation in the accepted sense, it would be difficult to explain how a sensation originally unpleasant may lose its unpleasant character by repetition, or even, eventually, become pleasant, as in the case of "acquired tastes." Pleasures and pains are mental facts accompanying simple sensations, and are the expression of different physiological effects produced or aroused by the stimulus. This is equally true at higher levels of mental life; the "pain" of a blow on the shin and the "pain" of a bereavement differ in mental quality. It may be replied with truth, no doubt, that the question of specific pain-sensations is largely one, not of psychological, but of physiological and pathological evidence, and that the apparently clear separation, in the skin, of pain from other cutaneous sensations, and its apparently independent peripheral mechanism, militate against the hypothesis that pain is only a qualifying factor in sensation.

From quite another point of view pain has been regarded as "a beneficent reaction of the nervous system against threatening forces"; in its teleological aspect it is considered to be "a grouping of disagreeable stimulations for the purpose

of communicating the existence of an injury to consciousness." One of the most recent contributions to the problem of pain from the biological or evolutionary standpoint comes from the pen of Dr. GEORGE W. CRILE, of Cleveland, the high quality of whose original researches on shock and allied states has been widely acknowledged. Dr. CRILE has expressed his views in his book on "The Origin and Nature of the Emotions" and again in his more recently published work, "A Mechanistic View of War and Peace." According to this writer, pain is one of the phenomena which result from a stimulation to motor action, and he goes so far as to assert that "without some associated muscular action there is no pain." His general argument is that the phylogenetic purpose of pain is to bring about appropriate muscular action, whereby the injuring stimulus or stimuli are counteracted. Illustrative instances readily suggest themselves—a foreign body on the conjunctiva or cornea and the associated pain and reflex phenomena, the nausea that precedes vomiting, the pain of stepping with the bare foot on a sharp stone, the discomfort of bladder over-distension. Going somewhat further, Dr. CRILE next asserts that the exanthemata are painless and pyogenic infections painful because the protective response of the body to the former is mainly chemical, whereas in the case of the latter an attempt is made to prevent the spread of infection from the original focus by immobilisation of muscles whose contractions would serve to diffuse the infection—a protective muscular rigidity, which is painful. On the other hand, should the pyogenic infection be situated in organs or viscera in which muscular action can play no part in restricting it, such protective muscular action, and pain, do not occur. "This explains why tuberculosis of the hip is painful, while tuberculosis of the lung is painless." Only those parts of the body that have been exposed to injurious contacts with environment are supplied with pain receptors, hence many intracerebral pathological conditions are, according to Dr. CRILE, entirely painless. As, in this view, the emotions are as purely motor excitants as pain, it is supposed that there may be a conflict between physical and psychical stimuli for the possession of the "final common path," and the assertion is made that psychical stimuli occasion a more rapid release of energy; hence they obtain possession of the path, and pain cannot be felt until the emotional excitation dies away. In the fury of battle the soldier may not perceive the pain of a wound because emotion holds the final common path, so that muscular action is for the time being prevented.

Yet the soldier is far from being always in a state of emotional overaction when he happens to be wounded, so Dr. CRILE argues that should a high-velocity projectile pierce his body at such a time no pain is felt because "the high-speed bullet is a recent development," and the "sense organs have not become adapted" to its stimuli, hence they cannot react. As a fact, however, a number of cases of instantaneous pain, in a limb, say, from injuries by rifle or machine-gun bullets have occurred in the

war, where the pain has been agonising and continuous, and where irritation of a mixed or sensory nerve has been the cause. No muscular action, by immobilisation or the reverse, makes any difference to the pain, nor does the pain lead to any particular muscular action. Again, certain pathological intracerebral conditions, in particular lesions of the optic thalamus, are not infrequently associated with unbearable pains, referred to the contralateral limbs, trunk, or face, yet the optic thalamus has never, phylogenetically, been exposed to "injurious contacts with environment." Dr. CRILE further asserts that if the kinetic system is so completely exhausted that no more muscular action can be excited pain is impossible. That pain exhausts the sufferer, and that with absolute exhaustion sometimes comes relief, is of course a truism; but another interpretation is surely valid—viz., that it is the exhaustion of the afferent, not the efferent, mechanism or linked neuronic systems from over-stimulation which leads to the cessation of the pain, as too bright a light blinds, too loud a sound deafens. Dr. CRILE's generalisations are very suggestive, and a perusal of his two works above mentioned, as well as of a third, "The Kinetic Drive," cannot fail to interest the reader. If we are not inclined to subscribe to all his contentions, we are grateful to him for his persistent efforts to seek an adequate physical basis for phenomena whose investigation used to be left too often to the metaphysician.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

SUBSCRIPTIONS.

THE following additional subscriptions to the Fund have been received:—

| | £ | s. | d. |
|---|-----|----|----|
| Dr. G. D. H. Carpenter (16th and 17th donations—total, £17) | 2 | 0 | 0 |
| New South Wales B.M.A. (per Dr. Crago, honorary treasurer) (total, £226 19s.). Queensland Branch ... | 34 | 16 | 0 |
| Fund initiated by Otago Division of New Zealand Branch of B.M.A. (second donation—total, £1012 15s. 2d.).—Medical Men in Otago chiefly, but many from other parts of New Zealand; Pharmacists of Otago and South Canterbury; Nurses in Otago; Otago Catholic Association and General Public ... | 407 | 15 | 2 |

Subscriptions to the Fund should be sent to the treasurer of the Fund, Dr. H. A. Des Vœux, at 14, Buckingham Gate, London, S.W., and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

THE APPEAL FOR SURGICAL INSTRUMENTS.

Surgical instruments should be sent to the Master of the Society of Apothecaries, Apothecaries' Hall, Blackfriars, E.C.

ACUTE ANTERIOR POLIOMYELITIS IN IRELAND.—Unfortunately, cases of acute anterior poliomyelitis, at least 60 to 70, have occurred recently in different districts of Ireland. It is known that 9 cases have been diagnosed in and about Ballieborough (co. Cavan), 3 or 4 in Carrickmacross (co. Monaghan), 3 in Newry, 12 about Castlereagh (co. Roscommon); 7 cases have been notified in Belfast, and 6 are now in Purdysburn Fever Hospital, while cases have also been met with in Holywood, Ballymena (co. Antrim), and in Markethill (co. Armagh), as well as in other districts. One of the characteristics of several of the cases has been the rather late appearance of paralysis, which has occurred a week after the onset of the feverish attack, naturally leading at times to a deferred recognition of this serious disease. Apparently, treatment has not had much effect.

Annotations.

"Ne quid nimis."

WOMEN AND THE LAND.

BEFORE the war the employment of women as workers on the land had become so much less usual than it was two or three generations ago, or had so completely ceased, that the present demand for their services found few able to respond to it. The women agricultural labourers in France and other continental countries continued and added to their daily toil on farms; our women were not ready to do likewise in any large numbers. Those whose grandmothers used to labour in our fields thought farm work "lowering," or regarded it as over-arduous, and, moreover, had acquired no training or experience to fit them for it. In these circumstances the sudden and urgent demand produced a supply of unsuitable persons from towns and villages, for the Women's Farm and Garden Union was practically the only existing institution which had interested itself in women's work on the land in time of peace and did not possess the means to meet a large demand. But a Women's National Land Service Corps, a war offshoot of the above society, was started to deal with the problem of meeting the immediate needs of the farmers. We commend the study of this body's interim report (which is published at the headquarters of the National Land Service Corps, 50, Upper Baker-street, London, N.W.) to women with physical and mental health and strength, who are anxious to do work very important in character and most helpful to our military cause, and who are not "out for money." Women workers on the land and organisers of such work are not paid at the rates expected by munition workers, or by the more highly rated employees of the War Office and the Admiralty, and their life will not be as exciting as that of the motor-car drivers who face danger and hardship near the front, but, nevertheless, they will be doing patriotic work, the need for which can hardly be exaggerated. Much of the work on any farm is well within the physical capacity of women. Milking and most of the duties connected with the care of animals may be taken as examples. But it is not only on account of the direct usefulness of the physical work to be done that the Women's National Land Service Corps should appeal to women. It can, indeed, supply training for a short period to women which will send them to a farm not quite in the position of raw hands, and it will thus test the suitability of the work to their capacity and temperament. It has, however, also as its object the supply of women to country districts who, besides doing their task for the farmer employing them, will help in the recruiting of other women, in organising the labour of village women, and in encouraging them by example to come forward. It has among its stated aims the supplying of county committees with organisers and trained speakers. It will be interesting to see how far women who entered upon farm work to meet an emergency will devote themselves after the war to an industry to any large extent which for several generations has possessed no feminine appeal. They will have found, or probably will have been able to introduce, better conditions than those which prevailed in the "old days." They will also be qualified to express opinions in the future when

educational questions as affecting country districts are reopened and when measures are being discussed for ensuring the return to the land of a larger proportion of our population.

HEAT STROKE, AVOIDABLE AND UNAVOIDABLE.

THE tragedy in the troop train from Karachi to Simla in June last, which was described at the time in our columns, came up again recently at question time in the House of Commons when it was stated on behalf of Mr. Chamberlain that no report of the inquiry was to be published. The statement was made that the Government of India have now issued revised regulations regarding the despatch of troops by rail during the hot weather, which should prevent the recurrence of such a tragic incident. In the face of this reassuring statement we are in entire agreement as to the uselessness of publishing details and of pillorying individuals who are now keenly alive to the possible dangers. The reply of the Secretary for State closes a chapter in preventable heat stroke. The 130 cases of heat-stroke which occurred on the *Dongola* during her voyage with wounded men from Basra to Bombay are in a different category. Seventeen deaths attributable to heat stroke occurred among the invalids and crew, and five others in which death was probably accelerated by the heat. The voyage was carried out under excessively difficult climatic conditions. On account of a following wind it was necessary during the early part of the voyage to put the boat about every four hours in order to get air into the wards. Here there appears to have been neither negligence nor ignorance; all that could be done in the trying circumstances was done, and the most regrettable fatalities were due to the fortune of war, and could have been neither foreseen nor prevented.

TICKLING COUGH.

Mr. T. Mark Hovell, President this year of the Laryngological Section of the Royal Society of Medicine, dispensing with a set presidential address, directed his introductory remarks to the therapy of certain common and distressing conditions of the upper air-passages, and especially to the relief of pain and discomfort. He agreed with Sir Richard Quain in ridiculing the idea that diseases of the throat are mostly of local origin, instancing many which arise from conditions existing below the diaphragm. Functional aphonia, granular pharyngitis, nasal obstruction connected with gastrointestinal or uterine derangements, were instances of such association, and treatment must be directed accordingly. In regard to one especially distressing symptom Mr. Hovell was helpfully suggestive, and if he was right in his conjectures cases of tickling cough may frequently be relieved of their terrors. For this condition he describes a frequent cause and an efficient remedy. He says:—

The cases of tickling cough which not only are very common after influenza, but which may follow a simple cold or occur without known cause, are frequently due to enlargement of the lingual tonsil, the cough apparently being produced by the swollen tissue coming into contact with the epiglottis. A solution of chloride of zinc, 15 to 30 grains to the oz., with a trace of dilute hydrochloric acid to thoroughly dissolve the salt, is in many cases sufficient to remove the trouble, but I am indebted to Mr. Morley Agar for calling my attention to the best remedy for this condition—namely, trichloroacetic acid. A very small quantity of this drug only is required, and it is best applied on a wool-holder bent at a right angle, with only a very thin layer of wool attached to it, so as to ensure the quantity of acid being small. It is best applied with the aid of a mirror, so that it can be accurately placed on the

swollen tissue. Enlargement of the lingual tonsil as a source of throat irritation, as far as I am aware, is not universally recognised, for if this were so the cases of paroxysmal cough which are so frequently met with would not be allowed to continue as they do.

In support of his contention Mr. Hovell cites a striking case of a lady of mature age who had for fifteen years been subject to violent paroxysms of cough, both by day and night, which began to lessen after the first application of trichloroacetic acid, and became only occasional after continued treatment. Another case with a seven years' history of cough took a similar course. Mr. Hovell conjectures that the violent paroxysms of coughing in whooping-cough may also arise from enlargement of the lingual tonsil. In two patients in whom the cough was very persistent he found this to be the case, and appropriate treatment gave relief. He suggests to those who have to deal with whooping-cough a trial of this method, combined with the administration of garlic, which he is in the habit of applying by cutting the segments of the root into thin slices to be worn beneath the sole of the foot between two pairs of socks. Whooping-cough paroxysms do not readily yield to any remedy at present in use, and would therefore form a good test object for the value of these methods.

THE CLEAN WORKMAN.

If the war lasts long enough and the Munition Workers' Committee continue their beneficent labours, industrial hygiene will reach a stage of development which might have required half a century of torpid peace conditions. The condition of the workman engaged in dirty employment and obliged to return home in his state of acquired grime is one that has long attracted the attention of thoughtful people as likely to result in loss of self-respect as well as the more or less marked aversion of his fellow travellers; but apart from trades in which the dust or dirt is poisonous, where the Home Office has been obliged to step in, little has been done to remedy the evil. Memorandum No. 14 (Cd. 8387, price 1d.) now deals with the provision of washing and bathing facilities for controlled factories in a way which should help to bring a drastic improvement. The Memorandum incidentally mentions a continental factory where hot and cold shower baths are provided for operatives engaged at sweaty or dusty processes and of which such free use is made that the workmen leave the premises spick and span. Attention is very rightly called to the practical impossibility of anything in the nature of evening recreation for the worker who must travel home, often a considerable distance, to get cleaned up before he can return to the city with his family. The installation of simple and practical lavatories is described in some detail, the suggestions being in the main identical with the regulations of the Home Office Order for pottery workers. In addition to such ordinary washing accommodation the Memorandum recommends the provision of bathing facilities for workers exposed to great heat and excessive dust. The cheapest and most efficacious installation is that of shower or douche baths, which produce not only cleanliness, but also a useful and stimulating effect upon the skin, militating against the catching of cold on leaving the workshops. The Memorandum suggests that workers may with advantage be encouraged to participate in the management of bathing facilities, and may

prefer in some cases to take a share of the payment. In workshops where baths are of special benefit to health and efficiency they should be provided within working hours. We trust the recommendations may be studied by employers and employed engaged in all dirty occupation, and that a result of this study may lead to a higher standard of personal cleanliness in the industrial world which will benefit health and self-respect alike.

TUBERCULOSIS OF THE TONGUE.
